"The celebrated Mr. Daniel Wildman will exhibit several new and amazing experiments, never attempted by any man in this or any other kingdom before. The rider standing upright, one foot on the saddle and one on the neck, with a mark of bees on his head and face. He also rides standing upright on the saddle with the bridle in his mouth, and by firing a pistol makes one part of the bees march over the table, and the other part swarm in the air and return to their hive again, with other performances too tedious to insert. The doors open at six, to begin at a quarter before seven. Admittance: Box and gallery, 2s., the other seats, 1s."

OUR LETTER-BOX.

CROOK'S IMPROVED INCUBATOR.—In answer to the inquiry made by a correspondent, we can now state that we have seen a very satisfactory testimonial relative to the hatching power of this apparatus.

ISLINGTON POULTRY SHOW—PIGEONS AT NEWCASTLE.—We have no less than six letters upon these subjects, and we feel that we shall act discreetly in not admitting any further discussion of the subjects. The Show we hope and believe will be successful, and we think similar Pigeon-judging will not occur.

WOODBURY FRAME-HIVES (C. F. G., *Kirton-in-Lindsey*).—Working directions, with dimensions, were given in No. 56 of this Journal, and in the last edition of "Bee-keeping for the Many."

SQUIRREL SHEDDING ITS FUR (*A Country Clergyman*).—The bald appearance of your young squirrel is probably owing to its changing its coat, and it will most likely soon regain its fur. Bread and milk, and nuts are its best food.

PRESERVING GOURDS.—"I. B." wishes to know if these can be preserved as a sweetmeat and how. Can any of our readers afford us definite practical information on the subject?

WEEKLY CALENDAR.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 66.6°, and its night temperature 45.0°. The greatest heat was 82° on the 25th, 1832; and the lowest cold, 26°, on the 26th, 1855. The greatest fall of rain was 1.68 inch.

BULBS.

(Continued from page 209.)

FORCING HYACINTHS IN POTS.

THE soil most suitable for the growth of the Hyacinth is loam from rotted turves that have lain in a heap in the full sun for twelve months, and been turned over twice. An equal quantity of fresh manure should be mixed with the turf at the time of laying up, and a bushel of soot sprinkled in at each turning. It is very distasteful to grubs and worms of all kinds; and unless the compost be free of these and other noxious grubs it is useless planting Hyacinths in it. If the compost is made as above it will answer well; but, if the loam is of a strong nature, one-sixth of sharp sand intermixed will much improve it, and prevent its binding.

Soils that form a close tenacious mass when pressed are unsuitable, and should, therefore, be avoided. If turf loam is not to be had, soil of any moderately light description will do, adding an equal quantity of leaf mould if the soil is strong, or of hotbed manure if it is light. A liberal admixture of sand will improve the compost if it is deficient in that substance.

The compost, let it be what it may, should be chopped pretty fine with a spade, and passed through an inch riddle, which will take away any large sticks or stones, and yet leave the compost rough. Close sifting is not to be recommended, as it is apt to render the soil a mass of mud; besides, the roots do not then run freely through it.

Pots 6 inches in diameter, which, I believe, are the 32-size of the London potteries, but 24's of many provincial establishments, are the most suitable, though bulb-pots, now out of fashion, 4 inches in diameter and 8 inches deep, answer admirably. As the roots of the Hyacinth penetrate to the depth of a foot or more in the open garden, it is only reasonable to suppose that deep pots are preferable to those which are shallow. Six-inch pots, however, answer very well for single bulbs; but where three bulbs are placed in a pot the size should be proportionately larger. Three bulbs do very well in a seven or eight-inch pot, and in three's Hyacinths are more effective than when grown singly. Pots 4½ inches in diameter, which are the 32's of some potteries, will answer perfectly for the smaller kinds of bulbs; in fact any size double the diameter of the bulb will do.

The compost being in a moderately dry condition, so that it will not bind when pressed in the hand, place a

large crock over the hole in the pot, and on this half an inch of moss, cocoa-nut fibre, or pieces of charcoal, and on this again an inch of the rougher parts of the compost. We have now secured perfect drainage, and the pot must next be filled to the rim with the general compost. The bulb is cleared of offsets and loose scales, but only such as are decayed or injured, and, placing the bulb in the centre of the pot, press it into the soil so that the apex may be level with the rim of the pot, or just a little above the surface. Press the soil gently around the bulb, leaving a half-inch cavity below the rim of the pot for watering, and the soil should slope from the apex of the bulb to the sides of the pot, so that water will drain from, not to, the bulb. If three bulbs are inserted in a pot they must be equidistant from each other and treated like those potted singly.

After potting give a gentle watering, and having covered a level plot of ground on a north border or any other open and cool situation with coal ashes, so as to prevent worms entering the pots, stand these on it, and invert a 60-sized pot, or, what is better, a thumb-pot without a hole in it, over the crown of the bulb to keep it dry, as it is apt to rot when brought in contact with wet plunging materials. On the pots from 4 to 6 inches of coal ashes are placed, or old tan, or anything of a similar nature. In this position they are to remain for a time, but how long is a difficult question to answer. However, we will let them remain six weeks if potted prior to the 1st of October, and only a month if potted after that date. The object of thus plunging is to let the roots be well established before the foliage starts into growth; which is an important point in their cultivation. Plunging is by many considered of vast importance. I have no hesitation in stating from my own experience that it is of no value whatever. For some years I was in the habit of plunging the bulbs that the pot might be filled with roots before the foliage started; but I often found the foliage had started and was of a considerable length in a short time, and that, I think, was in a great measure due to the depth at which the bulbs were situated. I have found from 4 to 6 inches sufficient covering, for when placed at a greater depth the foliage quickly grows towards the light, and from the depth of soil through which it has to pass becomes blanched, and it is hopeless to expect a fine spike on a short stem after the foliage is drawn to the length of from 3 to 6 inches. I have had these bulbs plunged in ashes and covered with a foot or more of leaves, and I found such treatment, though highly lauded by some writers and practitioners, far from conducive to success. It is necessary, however, to place the pots somewhere, and I have found that putting them on coal ashes in a cold frame immediately after potting, keeping the lights drawn down at all times except when heavy rains occur, is quite equal to plunging them; for the idea that any bulb will root sooner because the pot is covered with several inches of ashes is absurd, and the foliage will not start one moment sooner because it is exposed to the influences of the atmosphere. I three years in succession divided the bulbs as received into

three parts, and placed one lot in a cold frame plunged to the rim in coal ashes, and protected from wet by the lights; but at other times, except in frost, exposed to the air day and night. The second lot were buried to the depth of a foot in ashes; and the third plunged in a like manner to the depth of from 4 to 6 inches. This was done on the 14th of September, and on the 1st of November I found those in the frame with the apex large and closely clasped by the sword-like leaves, which were green and about $1\frac{1}{2}$ inch long, the roots matting round the pot. The bulbs under 6 inches of tan were in a similar condition, but not so well rooted as those from the frame, they were, however, in good condition; but those under 1 foot of ashes were grown to an extent of from 3 to 6 inches, and in many cases the apex was gone, no doubt from want of air and an excess of moisture. Both the first and third lot did well, but the first was the best, not according to my own judging, for my employer wanting to make a present of a dozen to a lady and selecting from the 150 then in flower, chose them without exception from it. More than this, I invited a florist, who sees things in a different light from a gardener, to inspect them, and out of the thirty-eight left of those placed in the frame he selected nine as the best, whilst out of one hundred composing the other two lots there were only three equal to the nine, although the sorts and quality of the bulbs were the same in each case.

The time of potting should be regulated by the period at which the bulbs are required to bloom. For early blooming they should be potted in the last week in August; but as they are rarely purchasable before the middle of September, a number should be potted at that time and placed on ashes in a suitable situation, as before directed, for from four to six weeks; but where a few are desired to bloom very early, the pots should be plunged to the rim in a gentle hot-bed, made by throwing up dung 2 feet high and covering it with ashes. This will produce a mild bottom heat of 70° or 75° , and excite a speedy root-action, and by exposing the surface to the air the bulbs will not be excited into top or leaf-growth. The heat of such a bed will only last for a fortnight or three weeks, at the expiry of which time the pot should be washed and freed from dirt, and placed on a shelf near the glass in the greenhouse where there is a free circulation of air, so that a strong growth may result. Here the Hyacinths are to remain until the first week in November, being duly supplied with water and the temperature kept above freezing. They may then be introduced into a house with a temperature ranging from 45° to 50° from fire heat, keeping them near the glass for three weeks, giving a little fresh air daily, and water of the same temperature as the house, so as to preserve the soil in a moist state never very wet nor very dry. By the third week in November they should be in a temperature of from 50° to 55° by fire heat, with a rise of 10° or 15° by day, keeping them near the glass as before, and giving air so as to encourage a stiff growth. In a fortnight the night temperature may be from 55° to 60° , which is the greatest forcing temperature I have found the Hyacinth succeed in, with a rise of 10° by day with fire heat, or 15° or 20° with sun. If due regard has been paid to keeping the plants near the glass, admitting fresh air, and watering, they will bloom finely a little before or by Christmas, when they may be removed to cooler quarters, yet the temperature to which they are taken should not be lower than 45° , or the plants will suffer in consequence.

Providing another batch of bulbs were potted at the same time, and put in some cold place to form roots, they should be removed to the greenhouse by the 1st of November, and placed on a top shelf near the glass, where they can have plenty of air (a great point in Hyacinth culture), by which means the crowns will swell gradually, and vigorous growth result. By the 1st of December the temperature must be increased to 50° by night, or the bulbs should be placed in that temperature, it being presumed that they have been kept for the last month in a heat of from 40° to 45° ; and in a fortnight the heat may be raised to 55° at night, which will bring the plants into bloom by New Year's-day.

Where a succession of Hyacinths is in request, another batch should be potted in the beginning of October, and afterwards every fortnight until the middle of December, the first three lots being plunged in ashes for a month, then kept a month in a greenhouse, and brought into flower by

an increase of heat, the first in the second week in January, the second in the beginning of February, and the third in the latter part of that month, to which those potted after them at intervals will afford a succession under ordinary greenhouse management, the late bulbs being retarded so as to bloom late.

For general purposes, however, two pottings are sufficient —viz., one in the second or third week in September of the early double and single varieties, and another in the first week in October, but not later than the second week; for though it is desirable not to plant them when a late bloom is wanted, yet as a rule, retarding the growth beyond its proper period has a deteriorating influence on the vigour of the bulb.

Presuming them to have been potted in the middle of September, they should be removed from their situation out of doors to a shelf near the glass in the greenhouse, and where they can have air on all occasions except in time of frost and rain, even then a little air is advantageous. If not required to bloom early let them have time; but if a few are desired early, the most forward may be placed in a temperature of 50° , and they will bloom in January. If not forced they will bloom in February, at which time and a fortnight prior to it, the minimum temperature should be 45° , and in this they bloom to perfection. When the truss, or rather the bells, begin to develop, every other watering may be of weak liquid manure, as the size of the bells will be improved in consequence, but after they are in full bloom the flowers will retain their beauty longer by watering with water only.

Those bulbs potted in the beginning of October should be treated in precisely the same manner as the first lot, with this difference, they must be protected from frost, and not removed into the greenhouse until the third week in November. These, if kept in an ordinary greenhouse, will bloom splendidly in March and April, the essentials to success being—1st. Placing the bulbs in a cool situation until the pots are filled with roots. 2nd. Keeping them near the glass, for the more light the greater is the elaboration of the food, and the more stiff is the foliage, the more compactly are the bells arranged, the stouter the stalk that supports them, and the brighter the colour of the flowers. 3rd. The size of the flowers, and the shortness or rather the stiffness of the spike depends on their having plenty of air on all favourable occasions. 4th. That they have no more heat than is sufficient to maintain the plants in a healthy, growing state, for the more naturally a plant is excited the more satisfactory are the results. 5th. A free open soil with plenty of vegetable matter. 6th. Perfect drainage, and being kept free from worms. 7th. A moist soil at all times, neither too wet nor too dry; but double the quantity of moisture may be afforded when the truss is nearly developed, every alternate watering being with liquid manure at the temperature of the house. 8th. When in bloom their beauty will last much longer if they are kept in an almost invariable temperature of 40° or 45° instead of a variable one, but they must be fully in flower or the colours will not be so bright, nor the flowers so fine, without a sufficiency of light and heat. 9th. The Hyacinth will bloom much more satisfactorily in a house from which frost is only excluded, than in one where more fire heat is employed.

HYACINTHS IN GLASSES AND BASKETS.

For growing in water the single kinds, because earlier and of stronger constitution than the double, are the best; but the double kinds have been and are satisfactorily grown in water. In choosing bulbs for placing in glasses let the main point be heaviness of bulb, and look well to the base of the bulb to make sure that it is sound; those showing signs of few or no offsets are to be preferred. October is the best month to place Hyacinths in water, which should be rain or pond water. The best glasses are those which are the most opaque; those known as Tye's are to be preferred, and triple glasses look better than single ones. Fill the glasses with water, and place the bulb therein so that the base of the bulb just touches the water, or, if anything, does not quite do so. Place the glasses in a dark cool place with a temperature of 40° or 45° for from four to six weeks, until the roots have grown to the extent of 4 inches; then gradually inure to light, and fill up the glasses with

water, which must be soft as before and well aired prior to using. The most suitable position is a cool room, as near the glass of the window as possible. It is not necessary to change the water: it may be kept pure by placing a few small pieces of charcoal in it, and the glass should be kept filled up as the plant takes the water up. If it become offensive, however, it should be changed. Sponging the leaves with rain water occasionally will free them of dust and contribute to their vigour. Fresh air, also, if it can be given without creating a draught, is of great value in securing stiff foliage; and light gives the colour to the flowers. Warm rooms are apt to draw the foliage and spike. Changes of temperature, as from a hot to a cold room or the reverse, are bad; and not less so is taking them from light to darkness or the contrary. After the roots are a few inches long the water may be lowered to half an inch from the base of the bulbs, as these occasionally decay when kept constantly wet. An airy situation is best, and if it be sunny all the better. The glass should be turned frequently, so that the foliage may not draw towards the light and become lop-sided, but be evenly balanced. Be very careful not to disturb the roots, and not to hurry in placing a support to the plant, only using one when it becomes necessary. If these hints be acted upon Hyacinths will bloom well in water, but they will not be as fine as those grown in pots. I was formerly of opinion that if a little liquid manure were added every morning to the water the bloom would be all the finer. I tried it, pouring every morning about six drops into each glass, and I thought the blooms were better than those which had none; but I very much question whether the liquid manure was really the cause. Perhaps some one will try it and communicate the result.

Hyacinths, with a variety of other early-flowering bulbs, are also grown in baskets, &c., in sand, moss, and a variety of other substances. The best material that I have found is cocoa-nut dust; it is light, holds a quantity of water, and when mixed with an equal portion of charcoal, reduced to the same degree of fineness as coarse-grained gunpowder, it answers very well. If a basket or bowl is to be used we first place a layer of rough charcoal at the bottom, and then fill to the rim within the size of the bulbs with cocoa-nut dust and charcoal, in equal parts, thoroughly incorporated, on this place the bulbs, and lastly cover them so that only the apex of the bulb is left above the surface. The material should be kept constantly moist; and after planting, the basket, or whatever it may be, should be placed in a dry, cool, dark place for a month, and then be fully exposed to the air and light, so that a vigorous growth may be encouraged. If desired, the surface may be covered with *Selinia denticulata* by planting it between the Hyacinths.

If Hyacinths are planted in moss or sand lay about half an inch of charcoal at the bottom of the vessel, on which place the moss, pressing it firmly down; and on this plant the bulbs, allowing the same distance between each as the bulbs are in diameter. Cover these with moss, except the apex, give a good watering, and keep in a dark place for a month; then remove to a light, cool, airy window, and surface the vessel with green moss, which will give a cheerful appearance to the whole. Water overhead two or three times a-week through a fine rose, with well-aired soft water, to clear the leaves of dust and refresh both top and root. This watering should be discontinued after the plants come into bloom, when they should be watered at the root only. In other respects the treatment of Hyacinths in glasses filled with water, or planted in moss or sand, differs but little from that of bulbs grown in pots.

G. ABBEY.

(To be continued.)

COCOA-NUT REFUSE FOR MULCHING RHODODENDRONS.

In the Number for August 23rd Mr. Robson has given some excellent instructions on the subject of watering. He says that all newly-planted surfaces should be covered, to prevent their cracking and hardening. There is nothing so good for this purpose as the cocoa-nut refuse. I was induced to try it from seeing it used in several gardens last year, and noticing the neat appearance it had. By

spreading it thickly over the flower-beds and round the fruit trees it prevents evaporation, and saves the labour of such frequent watering; another advantage is that the water is not wasted in running off the flower-beds on to the walks. I put some of this stuff round a plant that was nearly out of the ground, with its roots exposed, and some time afterwards I removed it, as the bed was too crowded, and was surprised to see the number of fine fibrous roots the plant had thrown out on the surface where this stuff had come in contact with the old ones. My neighbour's Rhododendrons are looking almost dead, whilst mine are in a vigorous healthy state. Both of us planted them in November; I mixed a quantity of the refuse with the earth, but he used none. I should think it a good plan to apply liquid manure by saturating this refuse with it, a little of which would be washed down to the roots at every watering.—H. E.

OUR METROPOLITAN FLOWER SHOWS.

NOTHING is easier or more common than to attempt to run down by abuse when argument fails; and I therefore attach very little importance to what is said by those who, intrenched in their own fortifications, think to overwhelm me by choice epithets. But why I am a wolf in sheep's clothing I know not, except that I have used moderate and temperate language, and I have the satisfaction of knowing that my views are shared by some of the leading men in the horticultural world. I have had, since these articles were written, opportunities of meeting them—both those who are exhibitors, and those who are simply lovers of flowers—and have been told by one and all that my views are correct; and I can only say that, if they are not so, I shall be glad to see the question quietly and soberly argued, but shall refuse to believe that such matters can be set down by assumptions of wisdom, or sneers at the ignorance of others.

Can, then, nothing be done to improve the appearance of our flower shows? or are they to remain in their present state of formality? In considering this question I have been led to a few conclusions, which may, after all, be worth nothing, and to which great objections, and valid ones, may be made, but which I shall, nevertheless, set forth.

In the first place, all the three great metropolitan exhibitions might be vastly improved by the addition of more verdure, to relieve the mass of bright colouring which the most of exhibition flowers present; but, instead of offering prizes for Conifers and the like, I would propose that these be supplied by the societies themselves. All have appliances enough for this purpose; and this is precisely the plan adopted by the Royal Horticultural Society of Ireland, Mr. Moore, the intelligent Curator of the Glasnevin Gardens, always sending in some fine plants to ornament their shows. I would propose that these be grouped in the most effective manner before the exhibition plants are brought in, and that the flowers be staged or placed as these fine-foliated plants demand. This, were taste displayed in the arrangement, would tend considerably to do away with the formalism that is complained of, but which, I think, very little strikes one at the Regent's Park.

Then I would certainly restrict the size of the pots in which the greenhouse plants are shown. This has been done with the softwooded exhibition plants; and I cannot understand that, with the skill and energy displayed by gardeners now-a-days, it is impossible to grow hardwooded plants in the same manner. I would not at once do away with the large plants, but I would offer prizes for greenhouse plants and Azaleas in certain sized pots, and do away with one of the present classes if needed. Great advantages would, I think, accrue from this to all concerned. The fact is, now, that no plant, however pretty, will be grown by those gardeners who exhibit unless it will bear twisting and torturing in all directions, and bloom at certain seasons; and then their size is so great that a few of them fill greenhouses, however numerous, and the proprietor loses all his pleasure in his garden for these enormous masses: hence it is that Vincas, Eriostemons, and such-like things make their appearance every year, and go the round of all the shows. But where are the Ixoras, Clerodendrons, and many other plants which used to be grown? Oh! they would not do—

i.e., they refused this nursing process. But then it is said, How can you supply their place at the exhibitions? I believe that a far larger number of exhibitors would come forward if they were not frightened by the recollection of the huge things they have to compete with, and then we should all gain by the greater variety of plants exhibited. One can now tolerably well name what plants will be shown before the day of exhibition comes; but were suitable plants required this would not be the case. Then, as to Azaleas, while one cannot but admire the skill displayed in producing such huge pyramids of bloom, I believe that half-specimen plants, allowed to grow more naturally, would be more pleasing to the general public. One remembers, in old Chiswick days, the plants shown by Mrs. Lawrence and others; they were not crinolines or hoops, and yet how beautiful they were! Therefore, I say, offer prizes for untrained greenhouse plants in ten-inch pots. The enormous pots for Pelargoniums, Fuchsias, and, I hope, Roses, are now for ever gone. Why not try what can be done with those plants which seem to be more intractable? There must, however, be one *sine qua non*—viz., that the size of the pots be unalterable—not to be changed at the whim and caprice of the governing powers; for these plants are not such as can be trifled with; and, as to training, I am aware that no plants can be grown without a certain amount of this, but I would consider that as little as possible should be intended by the term.

All cut flowers should be separated from those grown in pots. The plan of placing them in a long tent as adopted at the Regent's Park might be easily followed, and free access obtained by all who wished to see them. And might not something be done by offering prizes for herbaceous plants? There are many beautiful things in that class which we never see, but which are certain to please when well done. I remember with much pleasure in former days tastefully arranged baskets of these as shown at the Royal Horticultural Society's shows in Dublin.

I know of nothing more that in the present state of the matter can be done, and am convinced that these are sound views. Let us hope that something may yet be attempted to remedy defects where they exist; but let not the blundering and bad taste of one society be taken as a proof that reform is needed in all.—D., *Deal*.

PICEA AMABILIS NOT THRIVING.

ABOUT twelve years ago I purchased a *Picea amabilis*, which proved to be grafted near the collar. It is now about 7 feet high, and has been removed twice, the last time about four years ago. Last year it grew 9 inches, and this year it has grown about 3. During the dry weather the leader has dropped its leaves and withered. The stem has become nearly covered the whole length by something like the American blight, and which appears on the branches, and near the ends of them, and they are drooping. The ground is rocky below, and no water can remain near. The situation is quite open, and other plants have grown very well, though not fast.—J. G.

[We fear the fact of your tree being grafted has something to do with its want of success; added to which, most likely the situation is too dry, or the present season has been too much so for a plant not yet well established. Our own experience with this species is limited, but those to which it is allied mostly like a moister soil. The Silver Fir is found luxuriating on slopes and in dells where water is not far distant; and the finest Douglas Pine that we know is also in such a situation, and we know it fails to thrive in very dry places. We therefore think your tree requires a little more moisture than it has had this season, and probably another year it may do better. We have seen *Picea nobilis* thriving admirably by the side of water, and we believe *P. amabilis* was in the same neighbourhood. The former, however, also thrives well in the dry grounds at Linton. A specimen which had accidentally lost its leader many years ago remained several years without one; but it eventually produced a fresh leader, which has rushed up with all the symmetry and uprightness of a well-formed tree, and the growth for the last six years has averaged about 3 feet each year. The subsoil, though dry, is admirably adapted

to most forest trees. If, on the contrary, the subsoil of your garden is of an unfavourable character and the surface soil not deep, the result cannot be so satisfactory. The oozing out of white resin which you mention is a proof that something is wrong, but it is too late to remedy this season. Another year it would be better to supply the tree with water during the growing season if dry weather should prevail. We do not think any useful result will follow taking up and replanting unless you have reason to believe the soil bad and unsuitable. Another season the tree may do better.]

OLD AND NEW MELON SEED.

Do you consider old Melon seed to be preferable to new? If so, please state your reasons. Do you consider it more productive than new? If so, be so good as to state the reason why it should be so. A full explanation of this subject will much oblige—*AN OLD SUBSCRIBER.*

[Practically among good gardeners we consider there is little difference between the seeds of last year and seeds from three to six years old. Generally, when placed under similar circumstances the new seeds will produce the more vigorous plants, with the greater tendency to grow and make wood instead of setting the fruit quickly; whilst old seeds will yield plants of more sturdy growth, and be inclined to show and set fruit more quickly, because they are old, and it is a universal law in vegetable nature, that whatever tends to lessen vigour of growth will also tend to promote the production of seeds, the extra production of leaf buds and fruit-buds being in an inverse ratio to each other—a fact which, thoroughly understood, has led to many improvements in modern gardening. Practically, however, the age of the seeds of a Melon, provided they vegetate freely, is of less importance, as extra vigour may be neutralised by frequent pinching and disbudding (for the Melon does not relish much cutting with the knife), and more dryness, especially at the surface of the soil, when the plants show bloom. If much cutting is resorted to, the plants when very vigorous will be apt to gangrene if the wounds are not well dried or daubed with charcoal and lime. The luxuriance, when disbudding is well attended to, will often cause the fruit to swell very rapidly after they are set.

Plants from old seeds will generally grow much more slowly at first, and have a tendency in similar circumstances to be of a more short-jointed growth, and will, as a general rule, give less trouble in disbudding and setting. Though, therefore, if we suit our practice to circumstances there will be little ultimate practical difference, we can see the wisdom of our old gardeners in carrying new Melon and Cucumber seeds in their pockets some time before sowing, and thus, by the heat of the body drying the seeds, placing them in much the same position as older seeds as respects their growth.

The chief advantages of seeds one or two years old, therefore, over new ones are the less vigorous growth and the greater tendency to show fruit early. If the seeds are too old, so as to vegetate very slowly, and vigour cannot be imparted by rich nourishment, or the plants are too delicate to receive it, we arrive at the extreme of weakness—just as new seeds, if treated with rich compost, are apt to give us the extreme of luxuriance. Whatever checks the luxuriant production of stems and roots will insure earlier maturity. In old seeds the drying consolidates the carbon, and the starchy matter becomes to a certain extent converted into albumen; and this is less easily changed by moisture and the oxygen of the air into a sugary liquid than a starchy substance in the seed. On the amount of the sugary matter which the germinating seed can obtain will depend, in a great measure, the vigour of the young plant.

The matter may be simplified if we recollect that as a seed ripens the sugar, gum, and albumen are changed into starch; and then when we wish that seed to germinate we must reverse the process, and by the chemical agencies brought naturally into operation get the starch and the albumen converted again into sugar. As a familiar instance, look at a fine Marrowfat Pea, soft, and sweet, and fit for the table—how sweet it is! Taste it when ripe, and tasteless starch along with nitrogenous matters are its chief components. Make that seed germinate, and you again obtain

the sweet moist taste of the half-ripened Pea. So much is this the case, that we have sometimes wondered that our epicures do not malt their old Peas to make them soft and sweet again for the table. Sow the Peas as soon as ripened, and they will soon germinate vigorously; keep them for a year or two, and they will germinate more slowly and more weakly. Dry them very much when thinly spread out to a bright spring sun, and the seeds of last autumn will sprout little more vigorously than older Peas. Dry them still more in sunlight, and the carbon may be so consolidated that the application of moisture will cause rottenness to ensue instead of germination. Dry fresh young Melon seeds especially in the sun for a fortnight, and you will get the slower germination that takes place with older seeds. Dry them still more, and the vital germ may be unable to find any sugar out of the consolidated starch and albumen. Old seeds, therefore, require more care at the germinating period. The moisture that would suit a fresh seed would at once in an old seed produce rottenness and decay. Old seeds thoroughly indurated should be allowed to absorb moisture gradually. We have sown two pots of Melon seeds from the same packet, and taken from the same Melon four years previously. In the one pot we used soil slightly damp, and gave no water until the seeds were swelling; and the other pot we watered a day after the seeds were sown. In the first case almost every seed grew, in the latter case not a single seedling.

We might go on and yet not explain the matter more. Without referring to man; we might instance the animals generally reared for human food. The breeders act on the same principle, though applying it differently. A quick build of beef, mutton, or pork is their object, and to secure this the animals are well fed from the commencement of their existence. The gardener would do the same with a Melon plant if his object were mere growth of plant, bulk of stems and leaves; but as early fruit is his object, he rather lessens excessive vigour of growth, and old or well-dried seeds give him a weaker and stubbier young plant to start with.—R. FISH.]

QUALIFICATIONS OF SCARLET GERANIUMS FOR BEDDING.

ACCORDING to the definitions laid down by your able correspondent Mr. Robson as to the qualifications desirable in a Scarlet Geranium for bedding, it would seem as if he held the old Tom Thumb to be a criterion of merit in a bedder of these varieties. In fact, every property he names is at present almost exclusively inherent in that variety.

As Mr. Robson invites criticism, I am happy to second what he says in relation to habit, but I must differ entirely from him in respect to foliage. A shining deep green leaf is possessed by few Geraniums, except Tom Thumb. Crystal Palace Scarlet is the nearest approach to it, but this has a white-eyed flower, with faint traces of a zone or horseshoe. Little David is another near approach to Mr. Robson's standard, and the same may be said of Punch, but the habit is not so close as desirable: hence it is only suitable for large beds. Harkaway is another near approach to the standard; but the nearest that I can conceive is Lamartine, which is a good flower and a first-class bedder, but lacks the deep scarlet of Tom Thumb. Petit Mont Rouge very nearly approaches the standard, it being quite as compact in habit, if not more so, than Tom Thumb, with large flowers of a deep scarlet. Lady Middleton and Le Titien have finely-formed flowers, and are of a fine compact habit; but the colours being rosy scarlet are undesirable; and the same may be said of Lord John Russell, though its scarlet is deeper than the rosy scarlet of the last two.

Except Christine, Rose Queen, and Roseum Compactum, which are rose-pink-flowered, there are really no Geraniums with plain foliage, without horseshoe zones, that are worthy of a place as bedding Geraniums. In fact, I think the horseshoe marking a decided improvement, for I have found it very often heightened the effect. There are few Geraniums which surpass Cottage Maid, and yet this is possessed of most bold zonate leaves, and has a bright white eye. Baron Hugel labours under the same disadvantage (I am adopting Mr. Robson's standard), and yet it is quite as effective as

any of the plain-leaved Geraniums. Harry Hieover is another which comes quite up to the point of merit in every respect, except the horseshoe foliage and the reddish flower-scapes. Princess of Prussia and Scarlet Perfection would be all that could be desired, but for their horseshoe markings. Cerise Unique, with slightly zonate leaves, is the best of the rosy scarlets, the nearest approach to it being Sheen Rival, the flowers of which are of a brilliant cerise scarlet. Black-heath Beauty, with faint yet distinctly zonate leaves and pinkish blush flowers, is a good secondary-coloured Geranium, and one susceptible of great improvement, which I hope to see accomplished ere long. Lucien Tisserand, another boldly zonate-leaved kind with a large finely-formed bright scarlet flower, and Madame Rudersdorff, carmine salmon, margined with white, combining fine form with good habit, are also of the horseshoe section. In Whites, also, the best are found in the horseshoes. Again: take Stella, with which no Geranium can compare, and Baron Ricassoli; the latter shows the horseshoe marking more than any other Geranium, whilst in Stella it is indistinct, and the flower about as far from the standard of form as can be conceived. Greater part of those named would be discarded were Mr. Robson's standard adopted; and I should be loath to part with any of the horseshoe-leaved kinds for any improved plain-leaved variety of any colour. Except Tom Thumb, Crystal Palace Scarlet, Punch, Lady Rokeby (a near approach to the standard), among Scarlets; Christine, and Rose Queen, I would have nothing to do with any of the rest of the plain-leaved kinds.

As to the points themselves, I quite agree with those relating to habit; but differ with Mr. Robson in respect to foliage, thinking as I do that the horseshoe marking is a great advantage, enabling us to produce a greater variety of contrast, and to place Geraniums in proximity with some plants near which they would be inadmissible were the foliage not distinct as well as the flowers. In order to produce a pleasing effect it is necessary to study the contrasting of the foliage quite as much as the colours of the flowers. I cannot perceive that we should gain anything, but I am certain we would lose a great deal, by discarding dark-zoned Geraniums; and faint and reddish-zoned kinds, as Stella of the former, and Sheen Rival of the latter, owe much of their beauty and fitness for certain purposes through the marking of their foliage alone. For instance: it enables us to place plants nearly related in close proximity—nay, immediate contact, with each other; and thus we attain effect with a trifling alteration of materials. Nothing could be more telling than a bed of Geraniums which I saw lately. The centre was Cottage Maid encircled with a broad band of Christine, edged with Golden Chain. It is in a great measure the horseshoe markings of Cottage Maid that make it so effective. I should be very sorry to lose it and Stella, and would part with all others rather than them. I have included Stella, which is an intermediate variety between the Zonale and Nosegay, though more of the latter than the former, and I think Mr. Robson does not include the Nosegays.

As to the flower, I do not think there is reasonable ground for the objection to a white eye; and as to their near approach to the properties of a good flower, the further are they then from possessing that rare property in a bedding plant—profusion of bloom. It is noticeable that whenever a florist takes a "starry" flower in hand he makes it not fit to be seen as a bedding plant.

With the other remarks of Mr. Robson I most cordially agree, and hope the subject will be thoroughly ventilated, and the merits of the varieties recorded in the pages of this Journal. It is a topic worthy of the attention of practical gardeners and those interested in this most popular of bedding plants.—G. ABBEY.

STRAWBERRIES, ROSES, AND PEACHES.

It is in critical seasons that you find out what are the best Strawberries and Roses to have. I have received a letter from an amateur in Yorkshire, living in the fine vale of Mowbray, who confirms my recommendations given to him, and also to the public by the press. It is pleasing to me, who can have no private interest to serve, to find that

persons unconnected with trade indorse my recommendations.

As regards Strawberries, he says, after complaining of the drought—"Strawberries were soon over. Eliza (Rivers), Wonderful, Trollope's Victoria, Empress Eugénie, and Frogmore Late Pine held out, and perfected their fruit to the end of the season. Sir Harry, British Queen, Carolina Superba, La Constante, and others soon gave in and became prostrated. The five first mentioned appear to have wonderful constitutions, and are good croppers, of good flavour, and are right in either wet or dry weather—Eliza especially: it should have been named 'Punctuality,' because it never disappoints, whatever the weather may be."

Trollope's Victoria did not do here so well as usual, but the others did splendidly. I think President will supersede it. Mr. Taylor must add to the above five President, Royal Hautbois, Lord Clyde, and, as far as plant goes, Sir J. Paxton. I have fine plants, with bold crowns and strong foliage, of this "certificated novelty." Its fruit I have neither seen nor tasted; but Mr. Turner, whose word I can take, speaks very highly of it. It is a seedling of Mr. Bradley's.

North and south the nurserymen are short of runners of all kinds. All mine of every sort were in the ground and established by August the 9th. Spring-planted runners, worked plants, and fall plants are beautiful here. What they have cost me in water I cannot say; but *labor omnia vincit*.

As regards new Roses, Mr. Taylor writes:—"Maréchal de Serrurier is a trump. You must get it. Centre dark scarlet red, outer petals dark purple crimson; in the way of Madame Paul, but larger, fuller, and better. I fear many Roses will die this winter."

They ought not to die. I have never had a finer season. All mine were manured with decayed dung in July, and have been kept watered throughout the season. Once more, *labor omnia vincit*. I ran second in Class 1 at Kensington, September 6th, for twenty-four Roses (open). I cut for Weymouth, September the 9th, twenty-four beautiful trebles, and twelve beautiful singles. To-day (September 14th), I sent to the Bazaar at Dorchester twelve splendid singles (three yellows), and seventy-two Roses in trebles, and chiefly pure trebles. Five of these trebles were yellow Roses. I mention this to show the opponents of Manetti Roses what they can do when properly treated. I began with Souvenir de C. Montault on the 7th of May, and with the yellow Roses earlier, and I have had a profusion of noble Roses from that time to this. The walls are lined with splendid yellow Roses on the Manetti stock. I bought almost all of them of Mr. J. Keynes in the year 1860. They arrived November 17th in that severe year, and not one of them has died. I shall have good Roses till frost and snow set in.

As regards Peaches, the crop of my three trees has been 560. I sent to-day the last thirteen to the Bazaar, and they were the finest Peaches there.

To show the use of affixing your name and place of residence to an article, so as to afford readers an opportunity of verifying the truth of statements, and also of examining the management recommended, on Saturday, September 10th, Mr. Willett, of Portland Place, Brighton, honoured me with a visit to review these trees. He inspected them, saw such fruit as was left, and greatly admired the fruit, foliage, wood, and general management. I showed him the *cruel tenus*, and also how I intended to manage them after the wasp-defying hexagon was removed. I also showed him the Roses and the Strawberry plants. He told me that he could grow nothing at Brighton without glass on account of the furious winds; that he only grew forced Strawberries; that Peach trees planted out did better with him under glass than those in pots. I was very glad that he came and saw the truth of my statements. Since he has left I have given the trees their autumn management. I would rather persons came to see, than ask me to answer the stupid question, "Do Peach trees degenerate?" I will answer, however, the question, and say, They do degenerate, but, were they properly managed, they would not do so; for there is no tree here so easily managed, nor any trees in the garden, or beyond its limits, with such healthy and beautiful foliage.—W. F. RADCLYFFE, Rushton.

P.S.—My servant has returned from Dorchester, conveying the thanks of the lady stall-keepers, and their especial admiration of the Roses and Peaches.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 6TH.

FLORAL COMMITTEE.—A Sub-Committee was summoned to examine seedling Dahlias, &c., on the occasion of the autumn or cut-flower Exhibition, which proved, as might have been expected, a most signal failure. Had not seedling Dahlias, &c., been sent, the exhibitors at this Show would not have numbered ten. Messrs. Henderson, Pine Apple Place, exhibited *Gardenia florida variegata*, which had previously received a first-class certificate; also *Aralia Sieboldi variegata*, which had been commended in 1861; and *Allamanda Hendersoni*, a very fine seedling with dark green foliage, and large, bright yellow flowers of great substance, a decidedly good variety and distinct—to this a first-class certificate was awarded. Mr. Bull, Chelsea, sent *Dendrobium formosum giganteum*, a large white flower, the lip strongly marked with a broad yellow band, forming a very conspicuous feature. A first-class certificate was awarded to it. Mr. G. Smith, Hornsey Road, sent seedling *Pelargonium Prime Minister*, bright scarlet, white eye, zonate foliage, fine-formed flower of good substance, but not in condition for an award; also *Pelargonium Princess*, a pale rosy pink flower, with zonate foliage. Mr. Salter, Hammer-smith, sent *Pelargonium Beauté de Surenes*, one of the Christine section, with beautifully-formed flowers, large truss of deep rose, the lower part of the upper petals white; one of the finest flowers of its class—first-class certificate. From Mr. Stalker came *Verbena Gipsy Queen*, and *Verbena Minerva*, the latter the colour of *Prima Donna*, with a good truss—second-class certificate.

Messrs. Downie, Laird, & Laing sent cut flowers of six seedling Pentstemons. Mrs. Moore, a good-formed flower, rosy purple, with distinct white throat mottled with brown, received a first-class certificate; and Mrs. E. Clarke, pale red, with white throat deeply marked, a second-class certificate. Mr. Norford, Brompton, had *Verbena Purple Prince*, small compact truss, free-flowering, useful for bedding purposes—commended. Mr. Keynes, Salisbury, sent twelve cut specimens of seedling Verbenas, none of them sufficiently distinct from other named varieties.

Mr. Keynes sent, also, several seedling Dahlias, of which George Wheeler, fine form, pale lilac, back of the petals of a deeper shade of the same colour, had a first-class certificate. Champion, fine form, rosy purple shaded with maroon, had a similar award. Second-class certificates were given for Queen of Primroses, a large bright flower rather inclined to be coarse; and Queen of Sports, white striped with rosy crimson. The following seedlings were not awarded certificates—Tippy, Bob, President, Bird of Passage, Hercules, Matilda, Mrs. Reid, Hon. Mrs. Fox Strangways, and Annie Weeks. From Mr. Legge, Edmonton, came seven seedling Dahlias, but none of them of any particular merit—viz., Victory, Mr. Golding, Marvellous, Glory, Ellen, Crimson Perfection, and Excellent. Mr. Collis, Bethnal Green, had seedling Dahlias Annie and Princess Alexandra, the latter a promising Fancy variety, bright yellow ground, distinctly marked with crimson stripes.

TODMORDEN BOTANICAL SOCIETY.

MEETING SEPTEMBER 5TH.

The President in the chair. The attendance was unusually numerous.

Mr. Hobson exhibited admirable specimens, in the dried state, of the following North-American plants, all charmingly in flower—viz., *Dentaria laciniata*, *Anemone thalictroides*, *Arum triphyllum*, *Viola ochroleuca*, *V. blanda*, *V. palmata*, *V. pedata*, *Erythronium americanum*, *Orchis spectabilis*, *Cypripedium humile*, and *Sarracenia purpurea*; also the rare *Polypodium incanum*. The above were kindly presented by Mr. Hobson in augmentation of the Society's herbarium. Mr. Hobson also gave interesting details touching North-American botany. He referred to a new Spleenwort lately discovered by himself in Pennsylvania, and, as yet, unnamed.

Specimens were exhibited from Vancouver's Island of the under-named Filices—viz., Cheilanthes (*Cassebeera*) *farinosa*, *Botrychium virginicum*, *Polystichum acrostichoides*, *Adiantum pedatum*, *Allosorus crispus* (evidently identical with the British type), and a very peculiar form of *Polyodium vulgare*, with the tips of some of the pinnae terminating in a horn-like process, extremely curious, the horn projecting from a kind of pocket or sheath. The plant, if permanent in its peculiarities, might well be named *Polyodium vulgare cornutum*. Of this oddity only one example had been gathered in the island. The Cheilanthes above-named, as might be expected, is described as rare. Amongst other Cryptogams exhibited were unusually large examples of *Asplenium lanceolatum*, gathered by Mr. A. Stansfield, jun., on the coast of Merioneth.

PACKING ORCHIDS FOR IMPORTATION.

On perusal of your Number for September 6th, I observe information is solicited on the mode of packing Orchids for importation. I therefore venture to give a few hints from my experience.

As Wardian cases are not procurable wooden boxes must be used; packing in hampers of any kind would be useless. First, then, gather moss, not sphagnum or water moss, and thoroughly dry it, so as to be like hay, because it will then absorb any superfluous moisture from the plants, and likewise give out all that is necessary for their requirements. It must be borne in mind that the foliage and roots of the plants must be dry before packing. In doing this be careful not to fix the tops nearly so firmly as the roots, and both ought to be only moderately firm. For every layer of plants insert a few sticks to keep them in place. Now, as to the situation in the vessel: this must be between decks, in order to keep them at as equable a temperature as possible, but care must be exercised not to place them near any fire, or steam boiler. They will not need any airing on their passage, as once admit sea air to your plants, and destruction will follow. If practicable choose an overland route in preference to the long sea voyage. I condemn the use of charcoal, sawdust, cotton, bran, and the like, for packing, the absorbent properties of which would inevitably destroy the greater part of the Orchids before arrival, these materials having no power to give any portion out of what they take in. Having unpacked many cases in which these materials were used, I found such to be the result.

The above statements, based on my own practical experience, I tender with pleasure.

In a future paper (if agreeable), I will give a few hints on the importation of *Phalaenopsis*, *Sophronitis*, and *Burlingtonia*.—A LOVER OF ORCHIDS.

[Such a communication will be very agreeable.—EDS.]

I AM much obliged by the courtesy of "W. B. d'A." Mr. Williams's Manual I had already consulted, for I possess both editions, as I do Appleby's, which in some respects I value even more, though both are excellent. I have myself repeatedly imported Orchids from Brazil, and from the West Indies. My correspondents in these cases, acting under my directions, stuffed the plants in, when at rest, the former in barrels with no packing material, but about one-third of the whole bulk of small charcoal poured in over the plant; the latter in a large box with the long twining roots of a *Cactus* (dry) put between the Orchids for Dunnage.

The Brazilian consignments turned out in capital condition, dirty enough of course; but that I quickly got rid of by washing the plants in tepid water before I spread them on dry moss in the shade, or hung up those that were affixed to blocks. I lost scarcely a plant.

The West Indian lot also came over in beautiful order and prospered well with one or two exceptions. I am inclined, however, to prefer charcoal dust, especially if the Orchids are not perfectly at rest when packed, because of its absorbent and antiseptic properties. Your correspondent is in error in supposing it "heating" and "causing to sweat and rot." Its action is quite in the opposite direction.

But I have had no experience in importing from so distant a region as India; and since the great expense of Wardian cases and of the overland route is out of the question for

me, I wished to know how the evergreen leafy-stemmed kinds—as *Vandas*, *Saccolabiums*, &c., would bear being packed in closed cases and sent round the Cape.

Mr. Williams's information is most valuable, but he does not tell us whether the *Phalaenopsis*, &c., that he imported from Manilla (Manual, page 9, second edition), were in Wardian or in closed cases. He presently comes to speak of a close box in which *Phalaenopsis* was packed in dry bark, "a bad material" as he says, and as I should certainly suppose; but I do not gather whether these plants were destroyed or only retarded. Then he reports well of "plants" from India packed in dry soft shavings; but he does not say that these were of the *Vandoid* type, though I presume they were. Finally, he gives no hint by what route all these consignments came.

May I not hope to receive a considerable per-centge safe if my friend be careful to pack when thoroughly at rest, to fasten the heavier plants to the bottom, sides, and lid of the case, to stuff in very dry elastic moss with the lighter plants in the centre, and to throw in a peck or two of charcoal dust over all?

I may add, that I have received repeated consignments of terrestrial Orchids from South Africa, sent by the same friend, and packed in loose charcoal. Many of these have arrived alive, though the majority have been dead—a result not to be wondered at, when we consider that they were all *Ophrydeæ* with soft viscid tubers, diminutive in size, and taken up just when my friend happened to meet with them.

If any of your correspondents who have actually imported oriental Orchids would kindly give the result of their experience, mentioning in detail the form of package, the packing material, and the route, it might be valuable to many an enterprising—ORCHIDOPHILUS.

MR. BEATON'S BEDDING GERANIUMS.

We announced some time ago that the late Mr. Beaton's entire stock of seedling Geraniums had become the property of Mr. William Paul, of Waltham Cross. Since then many of these have bloomed, and during the past season of exhibitions some of the best of them have been seen at the principal metropolitan shows, where they have invariably attracted a large amount of attention and admiration, and notices of them have appeared in our own pages and those of our contemporaries. It is with pleasure that we now announce that Mr. William Paul will be prepared to send out, in the last week of October, nine of the most beautiful varieties that have already bloomed, varieties of which we truly say the like have never been obtained; possessing, as they do, not only novelty, but singular beauty of colour and remarkable profusion of bloom, such as have never yet been met with in the class of "Bedding Geraniums." At page 4 of our present volume, will be found some notes on six of the varieties shown by Mr. Paul at the Royal Horticultural Society's Show. From what we have seen of them subsequently, we can not only indorse the statements there made, but we can say that we have seen them in much greater beauty than they have been when shown at any of the great exhibitions.

A FEW DAYS AT MARLBOROUGH.

THERE are three oft-quoted Latin words which, being translated into plain English, mean "to enjoy one's leisure with dignity." Well, I happened to have some leisure; but as to the dignity of the thing, why, I am lying flat upon my stomach, having the stump of a sawn-off Oak tree for my writing-desk, with magnificent Ferns gracefully fanning my head and shading me from the noonday sun; and I am taking pencil notes on the back of a printed bill, which describes a cottage-garden show that was to take place in the grounds adjoining the ruins of old Savernake Lodge, Savernake Forest, on the 1st of August. When I write for the public I object to inform them whether I am busy or ill, circumstances for which I cannot deceive myself into the belief that they would care one fig about; but where to pitch my tent for a few days to try and relieve myself of horrid neuralgic pains in the head and face, that was the

question. Circumstances quartered me in the quaint old town of Marlborough in Wiltshire. Rambles about the downs, and long walks amongst the splendid scenery of Savernake Forest, soon worked health-giving wonders upon me. I would advise persons so afflicted, or indeed in any way afflicted, to take the train to Marlborough, to try a few days there; and if the country should have the same effect upon them as it had upon me, why I am compensated for penning this, and doubtless they would feel grateful for the recommendation.

Savernake House, the seat of the Marquis of Ailesbury, is about four miles distant from Marlborough. To enjoy a rich treat in woodland I would recommend the pedestrian to leave Marlborough by the Salisbury road, to branch off by the turnpike-gate up into the forest, where by observing the most beaten track between varying avenues, open dells, spreading Oaks and Beech, and Ferns and Mosses many, one is lured on and on till the "King" and "Queen" Oaks of the forest are reached. The former has a diameter of rotten trunk measuring 8 feet according to my walking-stick, and the monarch is otherwise shorn of his strength and beauty, having only one arm left, poised in mid-air, and, as a notice beneath it specifies, "dangerous." Her majesty reigns in the vicinity hale and hearty, and looking as if she might reign for a thousand years or more. Under the shadow of her branches is a favourite resort for gipsy parties—in fact, there was a small one ensconced there at the time of my visit, which prevented me from taking any measurements. Nevertheless, did any of my readers after some miles of walking on a sultry day, and feeling very thirsty, ever come suddenly near good people with tempting viands spread out and bottles not drawn dry regaling themselves? Torments of Tantalus! I left, and they made no sign.

Midway between these royal Oaks the late Marquis of Ailesbury caused a large thatched shed to be erected. I believe they call it the Chinese Umbrella, from its being a copy of an erection of the sort his lordship saw in the "Flowery Land," for the accommodation of parties in the event of a storm. It will shelter a large number of people. "It is about to be new thatched," said an old man whose life's work is nearly done, and who is employed by the Marquis to hobble about with barrow and broom to sweep up the leaves and other débris resulting from gatherings of convivial people. I expressed to him that it was very kind of the Marquis of Ailesbury to allow people to range about and to enjoy themselves uninterruptedly upon his property, and for him to anticipate their wants so considerately. The old man said, "My lordship is a good gentleman, and likes people to come and view his property;" and from what I learnt from numerous sources and in many ways his lordship is a "good gentleman."

Now, proceeding onwards from the Queen Oak, some fifteen minutes walking would introduce one to the monument, erected by one marquis in gratitude to another; as also to commemorate a thanksgiving for the recovery of King George III. from an affliction well known to history. From the monument a delightful though long walk would introduce one to the mansion, which can be seen in the distance; but necessity, not choice, would only incline me, a forest-loving pedestrian, to proceed farther that way; so, looking forward to the pleasure of viewing the gardens by another route another day, I returned into the bosom of the forest, and gave myself up entirely to the admiration of its beauties, meanwhile taking care to give the picnickers a wide berth.

In some parts of the forest the Holly trees are very fine, and many of them have a remarkable propensity for the Oaks, springing, as they do, with their bases literally growing out of each other, and again, above, leaning and weaving themselves into each other's arms in a most affectionate manner. One of these decorations of our Christmastide I computed to be quite 60 feet high, with a clear stem 8 feet high, 3 feet in diameter, and having a spread of branches 18 yards across. I also noticed another very fine Oak tree, though not of the same variety as the King and Queen Oaks—not can I say exactly to what species of *Quercus* it does belong—but it tempted me to bring it to book. Computing by my walking-stick, I give its trunk at nearly 8 feet in diameter, branching off at 12 feet from the ground into

three fine trees. My step gave it a spread of branches at right angles of 37 yards one way by 38 the other, and it has a tolerably regular receding top, I should imagine quite 100 feet high to its apex. I took a special walk to admire this fine specimen of Nature's handiwork. I ought also to mention that the lower branches have been cared for by some other lover of fine trees, by being propped up with stout forked posts, giving a Banyan appearance to it in the distance. These supports are unfortunately necessary, as symptoms of splitting are recognisable in the lower branches; and, to whomsoever the remark may apply, let me advise their speedy renewal, as the present supports are fast becoming rotten and useless. In a great measure the Oak and Beech trees are gracefully lightened up with a good complement of Birch, and a sprinkling of Sweet Chestnut. Many ancient Hawthorns, too, felicitously introduce themselves; and, when in blossom in the spring must appear like unto the driven snow laden with sweet incense.

For those who would like to enjoy good bracing constitutionals about the downs, it is a good plan to start by the Wootton Bassett road, past the new cemetery, over the common, and on to Rockley House, the grounds around which, and extensive clumps about the downs, were planted by the late Hon. General St. John, to whom, some years ago, this property belonged; the plantations, however, are past their best, from want of timely thinning. From Rockley strike on to the turf for any number of miles that one's legs can carry one; or, instead of the Wootton Bassett road, on arriving at the common take the Swindon road to the right, and, after a mile or two's walk, a fine, open, mild, though breezy country will be reached.

I now come to recommend a drive after the morning's walking, and host Carter's pony carriage became an admirable means to that end. We started by the London road; a mile's ride introduced us to the forest by the iron gate, and here an avenue of Beech opened to us not soon to be forgotten. I believe it extends three miles in length, and it is magnificent. The ground undulates in some parts of its length, which serves to animate the effect, as in rising and descending the trees seem literally to recede with a strange weird-like rolling movement, or gather themselves up, according to the line of vision in which the beholder views them. The clean pillar-like boles of the trees, and the gothic arch formed by the branches give an immense cathedral-nave-like aspect, whilst the light graceful foliage, to which the play of the air and light give animation, was a living picture of Nature worth coming many miles to see. At a break in its continuity at a spot called the Eight-walk Avenue, where drives branch off in so many directions through the forest from a pivot formed in a new plantation of Firs, we turned off, passing as we drove along the ruins of Savernake Lodge, which was unfortunately burnt down a few years since.

The forest becomes more park-like now as we wend our way to the farmstead, steam-saw mills, and workshops, in order to hunt up the clerk of the new district church of St. Katharine, and that accomplished the beautiful new structure soon became introduced to us. Truly a pleasant spot. A ha-ha with wall protects the churchyard, which is entered by handsome wrought-iron gates supported upon flint and stone pillars, of which materials the church is built in the shape of a cross. On entering the porch a superscription over the door leading into the church informs the reader, that "The Church of St. Katharine, Dedicated to the Honour and Glory of God, was erected by Mary Caroline Herbert, Wife of George William Frederick, Marquis of Ailesbury, A.D. 1861, in Memory of Her Mother, Katharine Woronzow, Countess of Pembroke and Montgomery, through whose Liberality she was Enabled to Build it." The style of the building is gothic, but to give a just, technical, architectural description of the structure with its details would be beyond my acquirements, and hardly appropriate even if I could do so for this Journal. Yet we stayed so long at the church that it was questioned whether it would be quite right to intrude on Mr. Johnson after six o'clock to visit the gardens; but I had formerly exhibited productions at our show at Woodstock side by side with him, therefore I claimed a sort of acquaintanceship, and from what I knew of him I felt sure we should meet with a kind reception he it late or early; therefore, a pleasant drive of a few minutes introduced us to his wood-embowered cottage, but unfortunately

not to find him at home. He was gone with the clergyman on a tour of inspection to the cottagers' gardens, in order to know to whom to award the prizes at the forthcoming show, for those allotments, &c., best cultivated. I gave our names to the damsel who came to the door, who, I suppose, reading disappointment depicted on our countenances said, "If we wanted to see the gardens the young men in the 'bothy' would show them to us, if we first went here, then there, &c. It would be rather difficult to find as their rooms in the garden were being rebuilt, and they had to make shift for the present." We soon found "the bothy," explained the wherefore of our appearance there, and became upon visiting terms at once with one of the young men, who, if our conscience would have allowed him, would have opened every pit, and unlocked every viney for our inspection.

"The bothy" was on the verge of the frame-ground, in which were seven or eight ranges of long pits containing Melons, Pines, and ornamental stove and greenhouse plants. A few glimpses sufficed to show that the occupants were in perfect order and receiving first-rate cultivation; but we could not resist a more close scrutiny of the fine-foliaged stove plants—a good collection and perfectly healthy, though on the *multum in parvo* principle. The plant of the collection was, we thought, a fine Allamanda Schotti trained around a globe trellis of wirework. One of its fine yellow flowers measured $5\frac{1}{2}$ inches across, and we were informed that some previous blossoms had been of a still greater diameter. There were, however, lots of fine noticeable plants, such as Dracaena terminalis, Coleus Verschaffeltii, Dracaena australis, Pandanus javanicus variegatus, Maranta zebra, Tydaea in varieties, &c. Numbers of choice Mosses, Ferns, and Orchids were there also, descriptively sufficient to fill pages of this Journal, so giving a last fond look we passed out and by a Mushroom-house, where one would not mind making a bet, from the manner in which our guide pointed it out, that there were good Mushrooms, and so through large doors into the kitchen gardens, and there we read old style with improvements creeping in, and from the hue of the vegetables it was easy to pronounce the soil to be in good condition. On we went, past some of the finest Black Currants we ever saw, into the second garden, glancing at the new rafters of a good-sized house springing up for the young men against and above the partition-wall, at the same time feeling not a little amused by observing a very old friend of ours, I include you Messrs. Editors! fall on the path from between the shirt and waistcoat of our guide, where he had hastily thrust it on our first appearance, no other than that current week's JOURNAL OF HORTICULTURE.

In the second garden the vineries and Peach-house are situated, four in all. The latter, about 100 feet long, has lately been erected by Mr. Johnson, and it is a structure after one's own heart. The newly-planted trees, some of which, taken from the open walls, are of considerable size, are looking healthy and promising well. Then comes an old viney partly occupied with very ancient Black Hamburgs, having just a *soucon* of mildew about them. This house is partitioned off, and the other compartment is filled with flourishing young Vines in pots. Next follows another house of the olden times, occupied with Lady Downes', Frontignan, and Black Hamburg Grapes. The fourth house had for its inhabitants the Tottenham Park (the late name of the place), and other Muscats, Black Prince, and Black Hamburg Vines. Taking the houses for all in all, better crops of Grapes, both early and late, could not be desired, and the Vines were in good condition—in fact the cropping was on the side of profuseness. Then, glancing at a good bed of German Stocks and Aster, coming on with unwilling steps, though quick, we trod the walk flanking the wall border, observing as we passed the healthy, well-trained Peach trees, which, after the manner of Peach trees on open walls, "used to bear, but do not now;" and, prophesying the removal of the huge old stumpy Apple trees and Filberts in the vegetable quarters, a door admitted us to the pleasure-grounds; so, turning round an instant to take a last survey of the whole, I reckoned the gardens, frame-ground included, to be about five acres.

Proceeding from the kitchen gardens towards the mansion, we paused to admire a fine Larch tree, reported to us by our conductor to be one of the original three first introduced into England. Its bole I computed to be 4 feet in

diameter, the spread of the branches being 31 yards across; proportionately for height, however, it was wanting in nice adjustment for the eye. A fine Magnolia grandiflora in full blossom grew hard by. The mansion now interposes—a square substantial house, which, when the improvements contemplated are all completed, will better suit the ideas of what a structure should be on so fine a property. From the portico a fine view is obtained, extending itself to Silsby Hill; a central avenue-like glade also strikes the beholder as being in almost unbroken continuity to the very verge of the distance. In the immediate vicinity of the house Mr. Johnson's mind has been active, and must be now by no means idle, as the amount of work lately done and doing shows—fresh turf laid down in seeds, green, fine, and level; a new raised terrace garden, with fountain for centre, supported by two antique vases on pedestals.

The flower-border devices have white stone moulded curbs, lined just within with a broadish band of orange-coloured sand, then lines of fine grass turf about the same width, bordered all round with Golden Chain Geranium. Tom Thumb is employed for scarlet in proportion to the quantity of white stonework, and for other colours principally Christine Geranium and Lobelia speciosa. The effect was good, though rather circumscribed; but then there was King Croquet and a bowling green to interpose themselves between a farther contemplated flanking of colonnade, with balustrade to match the end of the flower-garden terrace, and to hug the magnificent line of Rhododendrons, of which no consideration but their death ought to cause the removal; for we should conceive that bank of American plants to be one of the finest, if not the finest, to be found in our land. Deciduous trees, American plants, choice Coniferæ, &c., are disposed about the lawn—not quite pleasing to the eye, perhaps, after dwelling upon the "every alley has its brother" plan of the new garden, and the uniform character of the mansion; but who would willingly do away with old friends? Amongst them we observed a young Wellingtonia gigantea, planted by His Royal Highness the Prince of Wales, February 15th, 1863. A new end to the conservatory, flanking one side of the terrace garden, has been added, and it is entered from thence, as well as from the house, thus forming, in conjunction with the old conservatory and orangery, an admirable winter garden. A Musa takes its place in the centre of the new end, but the late-flowering occupants intended to fill it were being prepared for that purpose in the pits in the frame-ground.

We now visit the conservatory, in which new borders have also been formed and curbed with stone mouldings running their whole lengths. The borders are filled with greenhouse plants in pots, having fine pyramidal Fuchsias at intervals in the centre. An Acacia affinis, 12 feet in clean stem of 6 inches diameter, takes a worthy central position. The structure is glass domed. It is 70 feet long by 25, not including the new end, which is 30 feet square, and the whole is heated by two of Ormson's boilers.

From the conservatory we enter the orangery, a Grecian temple-like structure, the occupants of which were temporarily placed outside upon the terrace for the benefit of their health, and necessarily so, as the roof is covered in, though I believe the spirit of improvement contemplates a roof of glass. Symptoms of its having not long since been made subservient to the "light fantastic toe" were apparent in gas-fittings, a temporary boarded floor, and other marks. This structure measures 100 feet in length, including the handsome columned portico with its eleven steps, down which we go, and pass through large iron gates to find ourselves in front of that side of the mansion looking towards the monument, and discover the reason why the conservatory was built in the form of a quadrant, as the back wall there forms a balustraded wing to the house, having the orangery for a finial limb.

Another new wing and limb to match on the other end is now in course of erection, which will greatly add to the appearance of Savernake House, though the clink of the trowel was silent at our visit. Now taking leave of our civil and intelligent guide we jump into our vehicle, and course along through glade, avenue, and fine park scenery up to the monument, the undulating play of the ground and its features reminding one of the Long Walk in Windsor Park. From the monument, through the forest, past the monarch

Oaks about half a mile, when we turn off to the left, and arrive presently at the pretty little church of Cadley, built by the Marquis of Ailesbury a few years ago, as well as the parsonage within a short distance of it—both structures

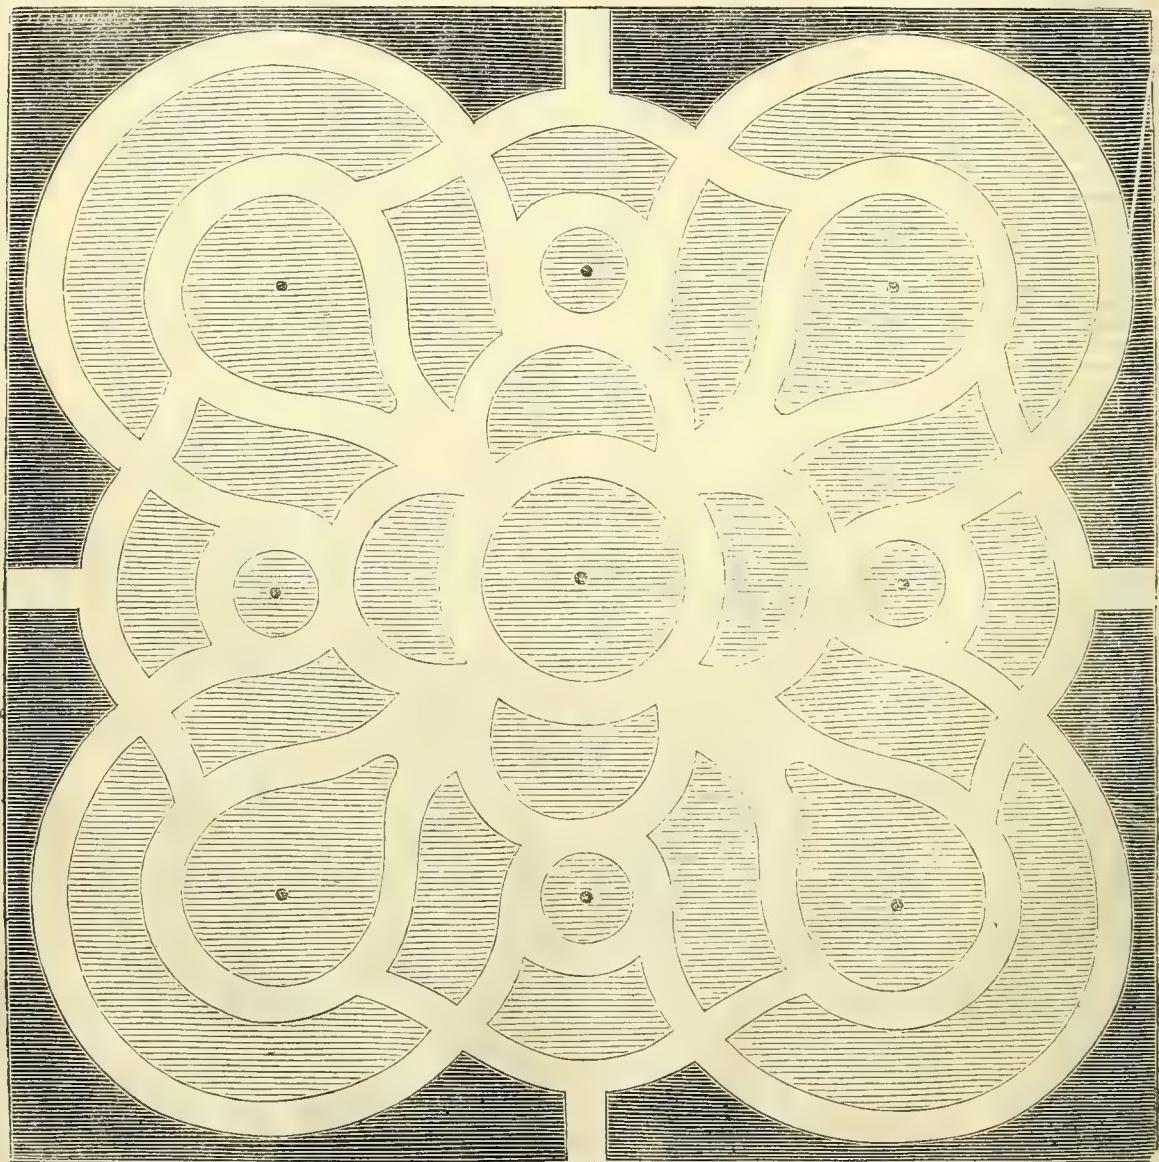

beautifully situated, truly pleasant spots either to live or to worship in—and so home to our comfortable inn in the gloaming by the Salisbury road, which skirts along just within the forest.—UPWARDS AND ONWARDS.

FLOWER-GARDEN PLAN—ADVICE TO A YOUNG GARDENER.

I AM a young gardener, aged twenty, with four years' experience of general work in kitchen, fruit, and flower gardens, and have also been accustomed to working in vineeries and Peach-houses; but never having been engaged where there was a good collection of stove and greenhouse plants, I have little experience with them, except such as are softwooded, but I have had much practice in the propagation of bedding plants.

I have devoted a considerable portion of my time to drawing, a specimen of which I enclose. The design is my own, and might suit a cottager who had a small plot to devote to flowers. I would plant Irish Yews in the circular beds, as marked in the centres.

I am very anxious to go to England, but I have a difficulty to encounter which I am afraid will be a hindrance to my obtaining a good situation—I cannot leave my present situation till the 22nd of November. Whether would you advise me to continue as a gentleman's gardener, or apply to such a professional as Mr. Newton, who advertises in your Journal? I have an inclination to pursue the latter course, because I have had some experience in levelling and laying out kitchen and flower gardens, and have a taste for and take particular interest in it. I have also a desire to have more of this than I am likely to have by continuing as I am.—A YOUNG GARDENER, Aberdeenshire.

[We have no hesitation in commending the plan you have sent for a flower garden in a square. If entirely your own

design it is most creditable to you at your age, and seems to indicate that your natural talents lead in the direction of

laying out grounds, and more especially as you have had some experience in that line.

Such a flower garden would look well in any position, but best when looked down upon. We have no objection to the four circles being of Irish Yew; but the garden would look well if grouped all over, and, instead of being suitable for a cottager, it is quite fit for the garden of a duchess. Such a compact well-balanced plan must be ever more satisfactory than placing a circle here, a star there, and a diamond yonder, without the least connection with each other. Your design so far fulfils the necessary conditions advocated by the late Mr. Loudon—namely, that no one clump could be altered in shape without spoiling the figure as a whole.

With regard to giving advice as to your future employers, and as to what line connected with gardening you are most likely to succeed in—these are matters which no stranger with the best intentions could well give advice upon, and the responsibility of which we are obliged to decline when our opinion is asked publicly or privately. The bent of genius in the individual will do more to determine the matter than the advice even of the best friends.

We have had many letters lately stating the writer's circumstances even more fully than you do, but making similar applications as to the ins and outs of landscape gardening, and as to whether it would not be preferable to leave a gentleman's garden and go into a nursery or a market garden in order ultimately to engage in one of these branches of commercial enterprise. The chief arguments adduced by such inquirers against the service of gentlemen are the low rates of wages given to gardeners, the objections often made to their marrying and having families, the amount of labour of body and of mind expected from them, the discomfort arising from the low estimate of their social position held by employers of men who elsewhere are regarded and treated as gentlemen of intelligence, the great uncertainty of servitude, and the liability of being dismissed without ceremony and without assigned cause after twenty or thirty years of faithful service, and a remuneration from which little can be saved for the future. These are some of the black points. Nothing is said of the kindness and the sympathy of so many employers, of the quiet and tranquillity of the gardener's life, of the worry and mental strain which he escapes on a Saturday or rather the Friday pay-night which the young tradesman experiences when he has men or bills to pay, and cannot obtain settlement of his own accounts to pay them, or the feelings which he must smother when for some trifling omission he is well scolded by a paltry customer, and dare not resent it even by a look of discontent, and when he finds there is trouble in serving the many as well as in serving the few. We have had penetration enough to see that in some cases the chief causes of discontent proceeded from an unwillingness to feel the working collar under any circumstances, united with the desire to be the gentleman, and to reach at once the top of the ladder by any or every means, by any or what help, instead of ascending step by step by self effort and self denial—the only steps open to young men of thorough self-reliant independence of character.

We do not for a moment suppose that our "YOUNG GARDENER" is one of the class who aims at getting on the crest of the wave, careless who sinks provided they can help him to swim; and therefore, though we would not advise him, we will make a remark or two, merely adding that our publishing his letter will be the best thing we can do for him, and the best part of any advice we can offer. First, then, we would advise him, as he is only twenty years of age, to go into a gentleman's place, or a commercial establishment where stove and greenhouse plants are cultivated; as, independently of the professional lore, the great variety of forms will expand and amplify his ideas, and make him fitter to act as a landscape gardener and the layer-out of grounds and gardens. We are supposing that, like most north-country lads, he must chiefly depend on his own resources for making his way in the world.

Secondly. If he resolves to enter on the landscape department whilst engaged in his usual avocations, he should not only study works on landscape gardening, such as Repton's, Gilpin's, &c., but he should make himself well acquainted with the outlines of all trees and shrubs as well as their names, and should omit no opportunity of visiting fine parks

as well as gardens and studying the effects produced by trees when in light and shade, singly and in mass; and this will be of great benefit to him whether he succeeds as the superintendent of a large demesne or follows the art of landscape gardening. The mere ability to draw pretty flower plots may fit him for laying out small suburban gardens, but will leave him quite at a loss how to grapple with more massive effects as they tell on the beauty and picturesque interest of a park or woodland scenery.

Thirdly. Having commenced as a gentleman's gardener, we would advise him to continue as such some time longer, until his mind were more settled and he saw clearly what would be best for him to do. Meantime, as stated above, no time would be lost; and such preparatory work might as well be done in Scotland as in England, there being as much to be learned in one country as the other.

Fourthly. Do not run away with the idea that in laying out gardens and grounds all is gold that glitters. No doubt the landscape gardener is treated by his employers as an artist and a gentleman, but that is a poor affair if it does not put something reliable in the larder and the kitchen cupboard. A few, very successful, may be able to keep their carriage and an establishment in unison. Of all disagreeables, there is nothing to us more repulsive than the idea of being forced to keep up the appearance of gentility, and stinting, screwing, and starving to make that appearance. Sooner would we wear the apron and the flannel jacket, have a little in our pocket, and be able to look every man honestly in the face. Amongst the number of clever gardeners we have known, who in their riper and best days have left Cabbage-growing for the line, the level, and the pencil, comparatively few have thereby increased their comforts or their emoluments. True, they were paid pretty well when they had a job, and were then generally treated with respect; but when there was nothing to do the surplus gains were soon exhausted in supplying their necessities. Except a very few who rise to a high position and are constantly employed, the most fortunate layers-out of grounds are those likewise possessing a mercantile establishment.

Fifthly. As to your coming to England. November and December are rather bad times unless you were insured of work beforehand, which is generally obtained through friends. In some nurseries they are busy at that time taking up trees, &c., and for a few weeks they will give employment to any one that suits them. For anything like a permanent job, that, however, can only be obtained by a good character and letters of introduction, and the best time for that would be early spring. The letters should come from your present master, or the gentleman, or some of either of their friends who know or deal with the nurseryman to whom you apply. If you suited there, you might remain or be sent to some gentleman's establishment where a young man was wanted. It is next to folly for any young man to come to London now without these letters of introduction. Even then he should have a few pounds in his pocket, as we have known young men tramp to every nursery round London and fail to obtain a day's work. The very number seeking employment keeps wages down.

And lastly. Whether you remain as a gentleman's gardener, or resolve to be ultimately a landscape gardener, lose no opportunity of improving yourself. Knowledge is always to be carried about, and it will be your own fault if it ever make you conceited and proud. The most intelligent man is generally the most humble and considerate. Above all, if your aim is high spare no effort to write clearly and correctly. In your short letter we detect eleven or twelve instances of misspelling. This is a crying evil even amongst some that write well, and is often done more from carelessness than want of knowing better. One of the best correctives is to take a favourite author, learn short periods by heart, then write them down, and compare each word with the printed copy. Many have thanked us for the advice, and it is far from such dull and dry work as ever and anon consulting the dictionary. In a short time the dictionary may be pretty well a fixture as respects spelling.—R. F.]

THE BIG TREES OF CALIFORNIA.—Let us first walk upon the "big tree stump." You see it is perfectly smooth, sound, and level. Upon this stump, however incredible it may

seem, on the 4th of July thirty-two persons were engaged in dancing four sets of cotillions at one time, without suffering any inconvenience whatever, and besides these there were musicians and lookers-on. Across, the solid wood of this stump, $5\frac{1}{2}$ feet from the ground (now the bark is removed which was from 15 to 18 inches in thickness), measured 25 feet, and with the bark 28 feet. Think for a moment; the stump of a tree exceeding 9 yards in diameter, and sound to the very centre! This tree employed five men for twenty days in felling it—not by chopping it down, but by boring it off with pump augurs. After the stem was fairly severed from the stump, the uprightness of the tree and breadth of its base sustained it in its position. To accomplish the feat of throwing it over, about two and a-half days were spent in inserting wedges and driving them in by the butts of trees, until at last the monarch of the forest was forced to tremble and then to fall, after braving "the battle and the breeze" for nearly three thousand years. This noble tree was 302 feet in height, 96 feet in circumference at the ground. Again: A short distance from the above lies the prostrate and majestic body of the "Father of the Forest," the largest tree of the whole group, half buried in the soil. This tree measured in circumference at the roots 110 feet. It is 200 feet to the first branch. By the trees that were broken off when this tree bowed its proud head in its fall, it is estimated that when standing it could not be less than 435 feet in height. 300 Feet from the roots and where it was broken off by striking against another large tree, it is 18 feet in diameter."—(*Scenes of Wonder and Curiosity in California.*)

A PRACTICAL UNTRUTH.

It is very humiliating at any time and for any person to be compelled to make a confession of a little shabby delinquency, and it is especially so in the case of amateur gardeners, a body of men usually considered remarkably free from any taint of moral turpitude; and yet I must make a clean breast of it, and confess before the world that I have been guilty of a little secret doing not quite consistent with the high standard of gardening morality: so out it comes.

On my lawn I have two rather large and very prominent beds, which are planted with choice Gladioli, the surface being covered with Mignonette; now it is known to all growers of this very beautiful flower that under a hot sun their brightness and effulgence soon fades, it will, therefore, be obvious that I found it a difficult matter during the late intensely hot weather to sustain the beauty of my favourite bed. What was to be done? Must I submit to be twitted about the failure of my horticultural skill? This would never do; so I set my wits to work. Now, independently of these two prominent beds, I have several patches of these beautiful bulbs planted at different times, intended for cutting for dinner-table decoration; when, therefore, any of the spikes of flowers in the beds on the lawn became "dowdy," I cut them down, and replaced them by spikes cut from the reserve-beds, and stuck into the ground amid the foliage of their decapitated *confrères*, giving them a plentiful supply of water. In this condition they continued fresh and beautiful, expanding every one of their flowers to the very apex; and no one suspected I had been guilty of so shabby a trick, and to this moment the mystery of my success has remained veiled! Forgive me, ye armies of "blue aprons!" Confession is one step to amendment, and this one step I have taken.—T. S.

A NATIONAL HORTICULTURAL SOCIETY WELL MANAGED.

TWICE has the Massachusetts Horticultural Society had occasion to erect a hall sufficiently extensive to meet its requirements; and when laying the foundation stone upon the second occasion, no longer since than the 14th of last month, its President addressed the assembled members. We will make but one extract from that address.

"Gentlemen of the Massachusetts Horticultural Society:—

"We are assembled here to-day, agreeably to your direction, to take the first formal step towards the erection of a building for the use of the Society, to more effectually carry

out its purposes of encouraging and improving the science and practice of horticulture, promoting the amelioration of the various species of trees, fruits, plants, and vegetables, and the introduction of new species and varieties."

"Such were the original objects of the Society, as named in the act of incorporation, and such, I am happy to say, they have always been, and, I doubt not, ever will be, as long as this beautiful edifice you are about to erect shall endure.

"It is since the completion of the former hall that the progress of the Society has been rapid, and its influence felt throughout the entire country. New life and fresh vitality were infused into the Society. It had the sympathy, as it had the substantial aid, of the public. It was appreciated as its founders intended it should be. Its objects seemed all at once to become apparent. It encouraged and promoted the science and practice of horticulture; it stimulated the production and introduction of new flowers, fruits, trees, and plants; it rewarded the cultivator for the best specimens of his skill; it gathered together, for the use of the members, a library of the most celebrated English and French works on gardening; it made known through its weekly and annual exhibitions all the choicer productions of the garden, the orchard, and the greenhouse; it awakened a taste for ornamental and landscape art, and it disseminated through its annual reports a vast fund of information upon every branch of horticulture."

We could name one or two gentlemen who ought to blush when they read this, knowing, as they do, how just the reverse is the truth if spoken of our Royal Horticultural Society.

THE EYE EDUCATION OF GARDENERS.

YOUR correspondent who signs himself "A MAN WITH AN EYE" seems to be very imperfectly acquainted with gardeners generally—I mean real gardeners; for it is not every man who "dons a blue apron and shoulders a spade" that can be truly called a gardener. While we see so many advertisements for a gardener who thoroughly understands the management of hothouse and greenhouse, kitchen and flower garden, and can look after a horse and chaise, and also wait at table, there will always be plenty of grooms and coachmen ready to style themselves gardeners for the sake of the little higher pay than grooms generally obtain, and, of course, as far as the garden is concerned, they will be found deficient in the required eye, and frequently of both visionary organs. I think it must be with such men as these that the "MAN WITH AN EYE" has had to do, and not with gardeners; for although a gardener myself, and by no means a perfect one, I may safely assert without fear of contradiction that gardeners as a body have very good eyes, seeing many imperfections in the places under their care that are quite unnoticed by their employers, and are too frequently powerless from the want of adequate assistance to remedy these (to them) visible defects. I am quite ready to admit the imperfections in many instances of gardeners—I mean men who from the early training and opportunities they have had ought to have become masters of the art of managing a gentleman's garden establishment, whether large or small; but still I would advise the "MAN WITH AN EYE" to become better acquainted with real gardeners before he continues denouncing them as so void of the properly educated eye. I have felt it a duty to vindicate the character of my fraternity, and sign myself, not a man with one eye only, but I hope—**ONE HAVING BOTH EYES OPEN.**

SUPPLYING LONDON WITH POTATOES.

FORMERLY the great Potato mart of London was in Tooley Street, and at the wharves which lie between that thoroughfare and the Thames vessels from all the ports on the eastern coast of England, laden with Potatoes, used to deliver their cargoes. The Tooley Street market, however, may be said to exist no longer, nearly the whole traffic in the carriage of Potatoes having been diverted from the coasting trade to the railways, and to the Great Northern in particular. So silently has this change taken place, that even railway shareholders themselves have not been aware of it, and therefore it was that the announcement made by

Mr. Packe, at the recent meeting of the Great Northern Company, that the directors were expending £40,000 in improving the condition of their Potato market, took his audience completely by surprise. A Potato market! Have we such a thing? Where is it? How possibly can £40,000 be required for any such purpose? Such was the exclamation, and such the inquiries which greeted the announcement.

These inquiries we shall now endeavour to satisfy, for the information not only of the Great Northern shareholders, but the public at large; and the facts and figures which we shall have to place before them are so extraordinary that they cannot fail to add to the astonishment and surprise which were then expressed. Scarcely had the line been opened when the Yorkshire Potato growers applied to the directors to afford them some facilities for the transport of their produce to the London market. Their request was complied with, and the conveyance of a few hundred tons of Potatoes in one season from Selby to London was the beginning of a carrying trade, which may now be roughly estimated at 85,000 tons a-year, or (taking one ton as sufficient during twelve months for consumption by a family of ten persons) an amount of Potatoes sufficient to supply the wants of 850,000 persons. Such has been the development of the trade in the course of twelve years; and as it is a growing trade, and one sure to be stimulated by the increase in the amount of accommodation afforded to it, it is not hazarding too much to say that before the lapse of another period of twelve years, one-half the entire population of London may expect to be supplied with Potatoes from the Great Northern Railway.

At present this trade is conducted by thirty-five factors, who have hitherto carried on their business in little wooden huts, not unlike sentry-boxes, paying a small toll to the company for the privilege. Badly, however, as they have been housed, they have been far worse situated in regard to the facilities of receiving and forwarding their consignments. They have been altogether without store accommodation, a circumstance which compelled them to get rid of the Potatoes the moment they removed them from the company's waggons, which, in itself, has been no easy task, owing to a deficiency of siding accommodation, and the consequent blocks upon the lines. On one occasion, as stated by Mr. Packe, there were as many as nine hundred trucks waiting to be unloaded. This must have been a great inconvenience to the factors, and no less an inconvenience to the company, whose rolling stock was to that extent crippled so long as the block continued.

The recurrence, however, of any such drawbacks is now about to be obviated, for the whole of the old terminus in Maiden Lane has been set aside as the area of the new market. On that site the company is now building a long range of warehouses, thirty-eight in number, fitted with dry and well-ventilated cellars for the storage of the Potatoes. In front of each there is fitted upon the arrival line a turn-table, communicating with a short line of about 60 or 70 feet long, which strikes from the main line at right angles, and runs up to the warehouse door—in other words, the line throws out here thirty-eight short spurs. Each spur is supplied with a wide platform, at which four waggons can with ease deliver their goods, to be at once carried into the warehouse, and stored there, either on the floor or in the cellars. It may not be out of place here to mention that in times of frost Potatoes are much safer in dark cellars than in places where they are exposed to the light. It will be seen by the above explanation that immediately on the arrival of a Potato train it can be broken up into as many portions as there are consignments in it, and that each factor can have the wagon consigned to him turned in upon his own 60 feet of line, and brought alongside his own platform, there to be at once emptied and made again available for the service of the company. The arrangement will be effectual against the recurrence of blocks, add to the capacity of the company's rolling stock, and enable the factor to take advantage of whatever demand may rule the market.

The facilities to be afforded to the delivery of the Potatoes will not be less convenient than those connected with the reception of them. The warehouses will also have a front towards Maiden Lane, but not upon it; for between them and that thoroughfare the company are constructing,

parallel to it, a wide and perfectly level road, on which the drays which are to convey the Potatoes from the factor to the dealer can come in, load at the warehouse door, and thence carry off the goods. The company, in order to guard against anything in the way of irregularity, will have their own constables placed at the gate leading into this private road, and their duty will be to see that each dray takes up its proper position, and does not loiter so as to inconvenience others.—(*Railway News*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

In dry weather hoe every part of the garden thoroughly, as those seeds that were ripened in summer (where weeds were allowed to perfect seeds and to shed them), have now vegetated and may be destroyed effectually, which is better than allowing them to remain till the spring amongst other crops. When a kitchen garden is at this season well stocked with autumn, winter, and spring crops, all neatly arranged and well cultivated, and the walks in good order, we think this is not at all the least interesting period of the year in this useful department of gardening. *Cabbages*, plant out immediately the main crop of spring Cabbages, and after planting them take the first opportunity of a dry day to fork over between the plants. *Cauliflowers*, prepare ground on a south border or other favourable aspect for planting them under hand-lights. A quantity may be pricked out of cold frames to receive protection from severe frost in winter. *Endive*, plant close under walls where they can be easily secured from frost. *Herbs*, make fresh plantations where required. *Lettuce*, prepare ground for plantations of Brown Cos and Hardy Green. A double row of them may be planted at the foot of the south, east, and west walls, the plants to be 4 inches apart in the row; and should they all stand over the winter, which is seldom the case, every alternate one can be removed to form other plantations. *Potatoes*, they may be taken up as soon as the tops are dead, but the late sorts had better remain in the ground for a time to ripen well. *Turnips*, thin young crops of these and Spinach before they become weakly and drawn, through standing too closely together.

FRUIT GARDEN.

Apples and Pears that have been gathered during the last fortnight should now be looked over carefully, when it will be found that those that were bruised or in any way injured have begun to decay, and unless removed will infect others. *Filberts* are now ripe in most situations and should be gathered. They keep well in a moderate-sized hamper packed firmly. Put the fruit-room in proper order for the reception of its winter stock. Use no straw or hay about the fruit, as materials of this kind are very liable to spoil the flavour of fruit laid amongst them. Handle the fruit, especially Pears, as little and as lightly as possible. Thin the leaves of early Cherry trees on walls so as to ripen the wood. Protect Plums from insects, and closely net-up *Impératrice* and other keeping varieties. Expose Raspberry suckers so as to ripen them thoroughly. Make new Strawberry-beds, clear runners away from the old plants.

FLOWER GARDEN.

The removal and transplanting of evergreens may be undertaken from the present time to November with more chances of success than at any other period of the year, and for large specimens no other season should, if possible, be selected. The natural warmth of the soil about the roots, and the close damp weather generally prevailing in the autumn months, are the principal causes operating to insure success. Add to this a principle, well known to those who have planted largely at all seasons, that plants form roots more readily after the season of active growth and during the ripening of the wood than at any other. Whether planting is done in masses or singly, the ground should be well-trenched and drained before attempting to put in a plant; for single plants, if they are intended to thrive, a mere round hole just large enough to hold the roots is not sufficient, but the ground for some space round should be well worked-up to facilitate the progress of the future roots, as well as the escape of water. As each tree or shrub is planted secure it from the action of high winds. Mulch the surface to prevent

evaporation from the soil, and give besides occasional waterings at the roots when the earth becomes dry, and then only sprinkle the tops well each evening, wetting the bark and foliage completely. Plant early bulbs. Protect Auriculas, from heavy rains. Pot the layers of Carnations and Picotees. Tie-up and regulate Dahlias as they bloom, removing all bad and small blooms.

GREENHOUSE AND CONSERVATORY.

House greenhouse plants before heavy rains come on, the tender sorts first; clean the pots and soil, stake, relabel, and clear off insects before they are taken in; Camellias and Azaleas to have a cool airy place. Herbaceous Calceolarias and Cinerarias to be shifted and grown on. Heaths and New Holland plants to have all the air that can be given by the sides and sashes being left open in fine weather. The most desirable objects to secure in the management of the majority of plants in these structures is procuring a robust and hardy growth, and lessening their vital activity that they may gradually accommodate themselves to the changing circumstances of the season.

STOVE.

Give abundance of air here at every convenient opportunity, to assist the plants to complete their growth in a strong and healthy manner. Sprinkle the walls and pathways twice or thrice daily, and dew the plants over occasionally with tepid water on bright days. Maintain a brisk temperature in the daytime, but allow the thermometer to fall to about 60° during the night. Twiners on the roof should now be more than ever kept within bounds, cutting back all shoots that have done flowering and tying the others, so as to obstruct the light as little as possible. Achimenes, Gloxinias, and Gesneras that are properly ripened off may be stored away in any dry place where they will be secure from frost; but take care to place them where they will be free from damp. Let any growing plants that require more pot-room be shifted as soon as convenient, in order to have them well rooted into the fresh soil before winter.

FORCING-PIT.

Those who intend to provide a rich display early in the spring should now select the plants adapted for that purpose. As one important division of good forcers we would recommend the ordinary American shrubs, many of which, although too large for the drawing-room stand, are well adapted for placing in conspicuous stations in the conservatory or mixed greenhouse. Of such are the various Rhododendrons, Azaleas of the nudiflora class, with various hybrids, the Rhodora canadensis, Ledum latifolium and thymifolium, Kalmia latifolia, angustifolia, and glauca, Andromeda pulverulenta, and Daphne, especially cneorum, and even the old Polygala chamæbuxus. Such should be obtained forthwith, potted in rather small pots, and plunged in the warmest corner of the garden, whence they may be successively introduced to the forcing-pit from the middle of November until February.

PITS AND FRAMES.

Continue to afford young stock in pits and frames careful attention, and endeavour to have it well rooted and strong without keeping it so close and warm as to render it sappy and liable to damp off on the first approach of winter weather, as is often the case with stock brought on in heat late in autumn, and then stored away in cold pits for the winter.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Cabbages.—In most places at all moist the most forward crop for early spring work must now be put in. We could not do so ourselves, as the ground was so dry. Our Cabbages will follow Onions; and for a depth of 2 feet the ground was white with Onion roots, and as dry as ashes taken from under a grate. No wonder that most of our September and October Peas refused to grow and produce as usual. The rain of Thursday night and Friday will help us greatly, and has given us a good supply in our tanks. Previously to its coming we had pricked out lots of the second sowing of Cabbages, with two or three small leaves. In mild winters these will stand better than the larger plants previously pricked out, and which, when raised in balls, will

suffer but little from the moving. Watered with sewage Coleworts, and Early Ulm Savoys, cabbaging nicely, and just needing a little more moisture to make them vigorous and tender. Went over the old plantation of Cabbages; cut off any split heads, stripped off any withered leaves, and left them between the rows, which will alike shade the ground and afford nourishment by their farther decomposition. Some of the larger outside leaves, stripped off previously, and scattered along the rows, maintained a degree of moisture about the roots of this useful plantation, which kept yielding most effectually, though from the beginning of June until Friday morning we have not had enough of moisture to penetrate the ground above a quarter of an inch. Now, after this rain, we shall know little more of drought this season.

We will not now regret the great care taken to keep things moving in the right way, when we could not give them the water they needed. We have never forgotten what was said by Mr. Barnes, of Bicton, some years ago, on this subject. It was to the effect that when fine weather came after frost, or, we may add, excessive drought, people were little inclined then to make any excuse for the deficiencies resulting therefrom. It is certain that, if by a little extra care and attention we could have prevented a disaster, and did not use that care, we should be haunted at least by our own self-accusations, and that, to sensitive minds, would be punishment enough. Extraordinary care to keep off a looked-for evil, even if the evil do not come, is much better than fretting and fuming over a disaster we did nothing to prevent.

Cauliflowers.—Watered with sewage water those that are coming nicely in. A few here and there are spindling prematurely; but the little sewage water and mulching have kept them generally in fine condition. We shall now be able to dispense with the old Peas that we kept standing, though rather unsightly, for the shade they yielded from the bright sun. The late Mr. Loudon, who did so much for gardeners and gardening, had an especial horror at seeing plantations of old faded Peas in a garden; so much so, that when he contemplated a northern tour in the autumn, a friend, who suspected that some northern gardeners were a little easy in this respect, wrote them to give them a hint to have all the offensive subjects removed. Even Mr. Loudon, however, with his fine taste for the tidy and the beautiful, would at once have agreed that there were occasions when these, usually so undesirable, should be made subservient to the useful. Utility will always have a beauty and an interest peculiarly its own. Not long ago one of our enthusiastic amateurs expressed his surprise at seeing several rows of these withered-haulmed Peas in our garden; but when he was desired to observe the fine Cauliflower between them, he out with his note-book to remind him, as he said, of the "wrinkle," as, even with the assistance of moderate waterings, he had not been able to obtain a close head of Cauliflower for the previous six weeks. With the smallest modicum of water these Cauliflowers owed their luxuriance and good heads chiefly to mulching and the flickering shade from the old Peas. We will now need the shade little or no longer. Our succession crops even when earthed-up are all mulched with long stable-litter, as we had nothing better to give them. Some younger ones had it spread over the ground, and but for the rains we would have done the same with the last plantation, put out chiefly for the purpose of lifting and placing under protection, or protecting where they are.

Pricked out a lot of young Cauliflower in a bed, the leaves the size of a shilling, as they were thick where sown, and this will render them stubby for being transferred to pots or under hand-lights. Both plans answer well; those in pots are kept under protection, shifted once or twice until the middle of March, and then turned out into rich soil. We generally obtain the heads pretty well as soon from hand-lights. In the larger size we plant out nine or more plants, and then thin in February or March to five. In the first part of the winter we do not mind the plants being frosted, as they are then small; and if the frost should be severe we then cover the glasses with litter, or a hood, made like that often used for bee-hives, and allow the cover to remain until the thaw has come and softened the soil inside, giving all necessary air to keep the plants stubby and hardy,

By the end of February we give less air, using the heat of the sun to make the plants grow, and covering them every cold night, and as the plants become large they are protected until the weather is warm enough to enable them to stand without their glasses. In planting under these hand-lights, or even in a bed to stand the winter, we usually cover the surface of the soil for half an inch or more with rough sand or roaddrift, which to a certain extent is a preservative against damp and slugs. A little dry slaked lime may also be put between the rows. The sand is what our amateur friend would have called a wrinkle. An old gardener of the old school, who was very fortunate with his early Cauliflower, told it to us as a great favour, and a secret we were to keep. He has long been beyond any regretting that we have not made the best of the secret in what he then considered the best way of treating it.

Lettuces.—Tied-up some behind a wall to succeed those at present in use. Planted out more in borders, some to be protected for winter use if necessary. Sowed the last crop as stated last week on rather hard ground out of doors.

Endive.—Watered the most forward and planted out more. Our Chicory will do little good this season, as owing to the drought it made no headway. However, we always find that Chicory and even Endive, however nice, are generally at a discount when a good Lettuce can be had. In our own case winter salad was once a matter of importance, but now it is comparatively seldom called for. In such cases some must be kept in case it should be wanted. It would generally be more satisfactory to the gardener if such things were wanted regularly or not at all, as then the best could be made of the room.

Cucumbers.—The same as to Cucumbers. What is the use of keeping up a winter supply, when a Cucumber is scarcely tasted at table from the middle of October to the middle of April? The places had better remain empty for several months, and fuel, fermenting material, &c., be saved. Those in frames should now have the linings banked up, to keep up internal heat, and the inside be kept rather dry, if we should have dull weather. Those bearing in pits should also have a little artificial heat in cold dull weather. Young plants, with two or three rough leaves, should now be introduced for winter supply, where winter Cucumbers are a feature. They are most easily grown in houses heated by hot water, and do best for winter in large pots or boxes, or in pits, where the roots are somewhat confined. One cause of success is to have the plants as strong as possible, and free from all sorts of insects, before the dark days come on, the plants being kept sturdy, instead of drawn, by plenty of air at all favourable opportunities. A second means of success, where the fruit is wanted chiefly at Christmas and onwards, is to allow the plants to bear little or none before the middle of December. We have seen plants loaded in November that were intended to carry on through the winter and the spring, but they mostly refused to do much good after the new year. We believe, ourselves, that one Cucumber before the new year will distress plants more than two or three Cucumbers after that period, when the sun, instead of waning, is gaining power.

Beetroot.—As we are upon salads, we may mention that our transplanted Beet has done well, and been in use for a month past. We think we shall transplant in future. For several seasons we have not been able to keep a seedling in the open air. No sooner did the red seed-leaves appear than it was whisked off. Even netting was not effectual, for the birds managed to find their way under it, and after chattering defiance with all the energy of terror, generally escaped before we could catch them. Sparrows and green linnets seemed the principal depredators. Young plants of the Lobelia kermesina were treated the same way. We were obliged to thread and net the lines to preserve them. There is so little in common between the Beet and the Lobelia, except the colour, that we are anxious to know if a similar crimson colour has been equally attractive elsewhere. We found the lines of small thread were quite as effectual in scaring the birds from the Lobelia as nets, or even more so; for they will walk round and round the nets until, acquiring courage, they will walk or crawl under them, getting their head in first, and, thief-like, their body afterwards. The stretched thread seems to impress them with some indefinable dread.

Celery.—We found our little heads of the Dwarf Incomparable Celery better than we expected, and have been using it for table for eight days. In ordinary seasons we could have had it good by the middle of July, though, like a good many other things, even Celery loses its zest when given too early or for too long a period. Our late friend Mr. Beaton found this out when he sent young Potatoes to table in November and December. He found it more prudent to send them in after the shortest day was passed and the new year had commenced. The new year gave a charm to the new Potatoes which they wholly wanted in the murky cold days of December. So long as prejudices are innocent, there is no harm in humouring them, and all the more when we are paid for doing so. We allude to this Incomparable Celery chiefly for impressing the importance of its being grown by the cottager and the amateur, who have little room at their disposal. Of course, our heads are rather small, but almost every bit except the outside leaves is fit for table, and we send from these little heads, about a foot in length to table, from plants about 15 inches in height. We have just measured the bed from which we are now raising the plants for cheese, &c., every day. It is 4 feet wide and 52 feet long, and has four rows in the bed, and seventy-one plants in each row, making 284 plants in the bed. The plants are just close enough in this dry season, about 10 inches apart, but there is still room for their growing larger, and in a dripping season were there some thirty or forty plants less in a bed, there would still be a great number of plants in a little space. Even now, small as the plants are, there is as much in them fit for table as is often met with in great, rampant, Giant Celery that requires much room and a great bank of earthing-up, besides the labour of doing it. From 15 to 18 inches on each side of the bed will be ample space for earthing-up. In fact, if the Celery were to stand long, 15 inches would be quite sufficient; so that for a space altogether from 6½ to 7 feet wide and 52 feet long, you might not only plant but earth-up 284 heads of Celery in fine order for the dinner-table. In a more dripping season some 230 to 240 very fine heads could be obtained. Our friends who can spare their 20 or 30 feet for a bed, may see how many heads they may have in little space. The landlord of a large hotel who has a large garden but never can obtain a tithe of the Celery he wants from it, took us to see his rows, and poor miserable stuff it looked after all his watering. He is now convinced that on the bed-system and with this dwarf kind he can have better produce and four times the quantity from the same ground. For early taking up, a trench may be dug out in the usual way. When intended to stand the winter and the spring, we prefer taking out little of a trench, but having the surface of the bed, after the addition of the dung, quite as high as the general level. When we dig a narrow trench to give the little earthing-up that is necessary, that helps to keep the bed dry in winter—almost as necessary to prevent rotting then as moisture is essential to growth in summer.

We have earthed-up finally another piece of the bed, so that our last earthed-up shall be ready for us in from twenty-five to thirty days; but owing to the plants being thick, they have not wanted that blanching time this season. In fact, when a string is placed round them the heart becomes white, whilst the top keeps growing freely. We use a few coal ashes next the stem, which keeps slugs, &c., from nibbling them.

Though the Celery is shorter than usual, owing to scarcely having any water after planting until the 10th of September, we have not, either with the Dwarf or a tall Red, noticed as yet a single bolted plant; and under the circumstances, the weather being so dry and no water at command, we attribute this result to the surface-stirring, the mulching with half-decayed leaves, and sticking a row of evergreen branches on each side of the beds. We are thus particular as to these points of detail, as some visitors, even after inspecting our empty ponds and reservoirs, would scarcely believe that we had not been watering at least twice a-week, and also because we should like to see a little bed of Celery in every cottage garden where the inmates of the cottage liked such a vegetable, and which they now generally consider beyond their reach.

The work done in other departments will be detailed next week.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 17.

But little alteration has taken place either in the supply or quotations since last week's report. Good Pines are rather scarce, but Grapes and Melons are plentiful. Peaches and Nectarines, though sufficient for the demand, are not so abundant. Of Cob-nuts the supply is rather short, and prices have advanced. The best dessert Pears consist of Louise Bonne of Jersey, Duchesse d'Angoulême, Williams's Bon Chrétien, and Marie Louise. Of Apples some very good samples of Ribston Pippin have made their appearance from Jersey. Cox's Golden Drop Plums have also begun to come in.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Wellington Road, St. John's Wood, London.—List of Bulbs and other Flower Roots.

Ambroise Verschaffelt, 50, Rue du Chaume, Ghent, Belgium.—Priv.-courant pour L'Automne, 1864, et Printemps et Eté, 1865.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

HYBRIDISED PLANTS (E. M., Southampton).—Your inquiries involve too intricate and too uncertain a field for us to reply to in a note; and to write upon it fully would occupy more time and space than we can afford. Practice will be your best guide. Experiments, presided over by a sound judgment, led the lamented Mr. Beaton to the success he attained. Many useful communications from him upon the subject are in our back volumes.

ELEMENTARY BOTANY (H. W. P.).—Henfrey's "Rudiments of Botany," and Macgillivray's edition of Sir J. E. Smith's "Introduction to Botany," will suit you.

FLOWER-GARDEN PLAN (N. C., Nenagh).—See what is said in reply to "A Young Gardener." See also many plans in this Journal, and in the cheap manual "Flower-Gardening for the Many." We can form no idea of the size of your grass plot, on which these clumps are placed in so thick and heterogeneous a manner. Even with the dimensions given we cannot undertake to furnish plans; but one of two things we would do, either have a regular plan placed in the middle of the lawn, with more lawn at each side; or, as the house seems to be in the centre, and facing the lawn, we would leave the lawn open, with the exception of a few ornamental trees, and we would run a row of small and less circles alternately all round next the narrow gravel walk, say 4 feet or so from it. You might then see your flowers as you went round the walks, and be cheered with the green turf between them from the windows. This would be a simple and elegant way of laying out the flower garden. At present there is neither plan, simplicity, nor elegance.

DIRECTIONS FOR PROPAGATING (A Young Beginner).—What do you wish to propagate? We cannot undertake to give, in one answer, directions for propagating all the plants in every department of the garden.

FLOWERING PLANTS FOR ROCKERY (Leighton B.).—You must not expect Stonecrops to flourish under the same conditions as Ferns. They are only suitable for light, airy, sunny situations as almost all flowering plants are; Ferns, on the other hand, luxuriating in shade and moisture. The flowering plants should have the sunny, and the Ferns the shady situations. Of Stonecrop or Sedum the best dozen are—Sedum Sieboldi, telephium, obtusatum, septangulare, Forsterianum, cepaea, Beyrichianum, hybridum, ceruleum, anopetalum, Ewersii, and kamtschaticum. There are numerous Saxifragas; as S. Stansfeldii (a good English variety), oppositifolia, and vars. alba and major, Andrewsi, cotyledon, cuneata, ciliata, granulata, granulata flore pleno, polita, rotundifolia, Sternbergia, grænlæica, and very many others all fine rock plants. Besides the above, the following would be suitable—Helianthemum vulgare in many varieties; Linum perenne; Geranium sanguineum, lancastriense, and Andrewsii; Iberis sempervirens, gibraltarica, and saxatilis; Hypericum montanum; Gnaphalium supinum; Dryas Drummondii and octopetala; Doronicum caucasicum; Draba verna, hirta, and hesperidifolia; Cochlearia officinalis and greenlandica; Cephalaria alpina and montana; Ceratium tomentosum, alpinum, repens, and Biebersteinii; Arctotis breviscapa; Ajuga reptans variegata and reptans alba; Achimilla alpina, montana, and fissa; Alyssum maritimum variegatum, saxatile, alpinum, and its variety variegatum; Antennaria margaritacea and triplinervis; Arabis alpina, stenopetala, procurrens, and bellidifolia; Vinca, &c.

MAKING GROUND IMPERVIOUS BY WORMS (V. G. C.).—A floor or bottom to stand pots upon may be made impervious to worms by placing a layer of lime riddings an inch thick, and then ramming it firm with a wooden rammer. Repeat this again and again, until a foundation is made 3 inches thick, on which place 6 inches of ashes. The bottom may be made more secure against worms by mixing the second layer of lime riddings with gas tar. It should be borne in mind that gas tar is death to any roots that come in contact with it. If you place 14 lbs. of lime in a tub, pour thirty gallons of water upon it, stir it well up, let it stand forty-eight hours, then stop the holes in the pots with clay, and deluge with clear lime water, the worms will come to the surface. Three hours flooding will be sufficient, then the drainage must be allowed to act. You could not have a better place for wintering Geranium cuttings than the room but little used, placing them on shelves, and unless the draught be great they will enjoy fresh air. You must take measures to guard against frost, wafering no more than is absolutely necessary to keep the plants alive. A dark place is very unsuitable: though it will do for old plants, it is not adapted for young ones.

STANDARD ROSES (A. Subscriber).—Standard Roses are apt to die off in light soils especially when budded on the Dog Rose; but we have them upwards of twenty years old, and very healthy even now. Cover the roots with manure in November, as you propose, and the winter rains will wash the greater part of the nutriment down to the roots. Do not prune until the beginning of March; and, unless the weather be very severe, the heads are better uncovered, but a little hay wrapped round the heads in frosty weather, to be removed in mild, is a great protection. We fear your thatching will do more harm than good, and we think it totally unnecessary, unless you have Lapland winters. If you do thatch them let Christmas be at hand before doing so, and remove the covering gradually, commencing about the middle of February, so as to dispense with it altogether by the middle of March.

DUTCH GARDEN (An Old Subscriber).—We think your Dutch garden will look very nice. If you wanted more flowers you might double it by filling that end of the mansion to the boundary by a similar plan. We approve of the plan for fruit trees at A. Then, for the space at B, in front of the house, we could not decide without seeing the ground and the surroundings; but in this, by way of contrast, we should think a few Pinuses, singly, as Arancaria and Deodar, and two or more circles of Rhododendrons, would suit you best, so as not to interfere with the lawn character of that front. If something of this were done the Dutch garden would be most effective, if shut off from the rest of the ground by a fence or wall.

CLOTH OF GOLD GERANIUM.—Will your correspondents state how this variety has behaved this season? With me the supposed strong-growing Cloth of Gold is no larger than when first put out, and not nearly so healthy; whereas Golden Chain, the slow grower, has been very satisfactory.—J. A.

FERNS (Mrs. H.).—There is no serial, either weekly or monthly, now publishing on this order of plants. Sir W. Hooker's "British Ferns" costs two guineas, and his "Garden Ferns" are of the same price.

SEEDLING PANSIES (L. F. F.).—All of ordinary merit except one with white ground, yellow eye, and pale lilac edging to upper petals, and lilac pencilling of the lower petals.

HOLLY NOT THRIVING (E. C. S.).—It is not at all unusual for a large Holly to look badly for some years after transplanting; and we are far from certain that severe pruning would do it any real good. The fact of your Holly hedge not doing well is a proof that your clayey soil is not the proper place for it. We would, however, remark that digging a trench, or rather ditch, by the side of the Holly hedge, so as to just cut the tips of the roots, and filling that ditch with sandy road-scrapings, will most likely induce the roots to strike into a more genial medium, and produce a healthier state of things.

EMIGRATING TO NEW ZEALAND.—We have received the following in answer to the query of "E. W." "A gardener would do well in New Zealand that would work, dig, mow, sow, or be handy at anything, as the country is rough yet, and gardening there is very different from here: A friend who went nearly five years ago has saved £30 per year, with a small family, but works at anything. The work is not harder than in England. The day is reckoned eight hours for work. What seeds to take, or any other information, I should be glad to give; but I advise 'E. W.' to think well before he emigrates, as it is a very serious journey.—W. C."

INDEX (Bert).—Vol V. concluded with the year 1863, and the index was published with No. 146, January 12th, 1864. We suspect you mean Vol VI., the last Number of which was published on the 28th of June. By sending your address, two postage stamps, and the number of the Volume, the proper index will be forwarded to you.

PLANTS AND HARDY ANNUALS FOR SPRING BLOOMING (Leighton B., and W. Browne).—Saponaria calabrica (rosea we do not know) will bloom in spring if sown now, but it is not so hardy as many. We intend publishing some notes on annuals, and early-flowering spring plants, for flower-garden decoration shortly.

DISTORTED SALIX SHOOT (F. W.).—The flattened stem, or branch, is not uncommon, and is called by botanists fasciculated, or clustered. The cause, like the cause of most abnormal formations, is unexplained. Sir J. E. Smith says it arises from disease or accident, and is frequently observed in the Ash, the *Tamus communis*, several species of *Daphne*, *Asparagus*, &c. In one variety of *Pisum*, called the Top-knot Pea, this deformity is permanent, and propagated by seed.

CELERI, &c. (Guernsey Blue).—In recent Numbers of this Journal full directions have been given relative to Celery culture and Mushroom-bed-making. "The Garden Manual," which you can have free by post from our office for twenty postage stamps, contains information on these subjects, and all ordinary cultivation required in the kitchen, fruit, and flower garden.

PROPAGATING CENTAUREA ARGENTEA (A New Subscriber).—Take up the plants and pot them in a light turf loam with a quantity of sand intermixed. Provide perfect drainage, be rather sparing of water, and place them near the glass in a light airy part of a dry greenhouse. Do not reduce the head at all, but retain it and all side shoots. In February place the plants in a house having a temperature of from 55° to 60°, which will encourage the production of side-shoots, and when these have three joints they should be slipped off, or cut off with a sharp knife near the stem, which will leave a kind of heel on the cutting. Insert them in moist sand in a pot or pan, and place in a mild hotbed of from 75° to 80°, putting a bell-glass over them if the atmosphere of the house is dry; but if it is calm and moist the bell-glass may be dispensed with. Keep the sand moist, but avoid moistening the foliage, and be careful not to drown the soil, otherwise the cuttings will damp off. They will root in a fortnight or three weeks and may then be potted; continue them in heat until they become established, then remove them to the greenhouse and gradually harden off prior to planting out, which may be done in June.

PERPETUAL CARNATIONS—WINTERING GOLDEN CHAIN AND CLOTH OF GOLD GERANIUMS (Agnes).—The Perpetual Carnations are similar to Perpetual Roses. They bloom more or less continuously, especially when grown in pots. It is not usual for them when kept in a greenhouse to continue doing so through the winter. They flower most profusely in summer and autumn. The Geraniums you name should be taken up on the approach of frost, potted, and wintered in a greenhouse. A rather warm, dry, airy, light situation is best. They should have but little water—only sufficient to maintain their vitality. By the faggot-plan we presume is meant tying the plants in bundles like faggots, and that you appear to understand, which is all the information we can give in reference to it.

SELF-INSTRUCTION (A Young Gardener).—Loudon's "Self-Instruction for Young Gardeners" will teach you how to draw simple geometrical figures. If you wish to learn perspective and colouring elevations you must receive a few lessons from some local drawing-master.

NAMES OF FRUIT (A. Middleton).—1, 2, Keswick Codlin; 3, not distinguishable from the specimen sent; 4, Easter Pippin; 5, Blenheim Pippin. Pear too far gone. (J. F. Lambert, Dublin) **Apples.**—1, Whorle Pippin; 3, Newtown Pippin; 4, Royal Russet. (An Old Subscriber, Peckham) **Pears.**—1, Gansel's Bergamot; 2, Bourré Deil; 3, Glou Morceau, small; 4, Bourré de Rance. (New Subscriber) **Apples.**—1, Bedfordshire Foundling; 2, Loan's Pearmain; 3, Birmingham Pippin; 4, Lemon Pippin; 5, Robinson's Pippin; 6, Sack and Sugar; 7, unknown. (*Anicus*).—Your Peaches are certainly most extraordinary. They are evidently the produce of two distinct ovaries in the same flower, which have become united by close contiguity, forming a curious junction. (E. B.) **Apples.**—1, Gravenstein; 2, Bleheim Pippin; 3, Cellini; 4, Duchess of Oldenburg; 5, Christie's Pippin. (J. W. J.)—1, St. Germain Pear. **Apples.**—2, Hawthornden; 4, Dutch Mignonette, 5, Reinette du Canada. (T. H. R.)—1, Syke House Russet; 2, Blenheim Pippin; 4, Hoary Morning; 5, Dumelot's Seedling; 7, Nonpareil; 8, Spice Apple; 10, Devonshire Quarrenden; 11, a sort of Crab, Pear.—B, Williams's Bon Chrétien.

NAMES OF PLANTS (P. W. A.).—Your deciduous shrub is *Rhus cotinus*, or Venetian Sumach. (B. S.)—Your plant belongs to neither of the genera you mention, but is *Arenaria serpyllifolia*. (S. A. P.)—*Myrica Gale*. (*Morphe*).—5, *Scabiosa succisa*; 6, *Caucalis infesta*; 7, *Impatiens noli-me-tangere*; 8, *Sedum telephium*. (H. K.)—Your Fern is too young and imperfect to be named. The yellow flower is a species of *Helianthus*, but it is impossible to say which from such a mangled scrap. The other plant is *Origanum virens*. The Pear is Summer Franc Real; the Plum, Pond's Seedling. (F. C.)—We cannot tell the name of your Leper plant. It appears to us to be one of the Compositæ.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY IN A SMALL ENCLOSURE.

In reply to "A COUNTRY VICAR," we will begin with the old quotation—

"Choose not alone a proper mate,
But proper time to marry."

There are fowls evidently intended by nature for such a place (8 feet by 20) and such purposes as you describe—viz., to live in such a small place, and to produce eggs. No one would try to rear chickens without more run; and no amount of food will make the fibre and muscle, and produce the growth that can only result from exercise. Therefore some breeds are layers only: the hens never sit. Pullets, the first time of laying, will produce their number of eggs, but when they become hens they will not. You may choose Spanish, or Crève Coeur, or La Flèche; they are non-sitters. You may have Cochins or Brahmases; they are very hardy. We would advise you to have Spanish, Brahmases, or Cochins. You must every year save some eggs, and put them under other fowls, to produce April or May chickens. These will

lay in the winter. When they are hens they may be kept as breeders, or sold. If care be taken of all the scraps in a house, and certain waste from the garden, the laying hens should cost little, and cottagers will always rear chickens at a low price. Where everything is bought, and fowls are luxuriously kept all the year, eggs cost one penny each. Where fowls are tended and cared for carefully, eggs should be cheap food.

LEIGH (LANCASHIRE) POULTRY SHOW.

THIS Show took place on Wednesday, the 13th inst., on very suitable grounds adjacent to Leigh, Lancashire; but it is now made evident, that should the Leigh Show progress during the ensuing five years as it has during the same number of years just past, a far more extensive appointment will be compulsory. The fact may be very briefly told. In the northern counties the emulation of the numerous agricultural societies held in those districts has scarcely any bound assigned to it, each exerting itself in the most friendly rivalry to excel its neighbours; consequently, the northern counties have progressed in about the same proportion as those of the southern and eastern districts have, on the contrary, retrograded. The reasons are obvious: in the north the hopes of committees of agricultural societies are the determination to establish a show as good, or even better, than those held around them. All try their best, yet, barring a little customary banter, the most friendly feelings prevail. Necessarily from this cause alone, good well-attended meetings are the almost universal order of the day, the exhibitions being, as a whole, of first-rate character. The people of these districts seem most thoroughly to enjoy them, and we rarely hear, therefore, of non-success. The southern districts of the kingdom unfortunately seem far more supine; committees do not appear to labour as impulsively and willingly together. "The work"—this always may be regarded as a sure test of sincerity or otherwise—at the last devolves exclusively on, perhaps, a tithe of the original projectors; and thus fairly borne down by the excess of responsibilities falling on one, or at best a very few, pairs of shoulders, the attempt is finally abandoned, and thus shows that might have redounded to the credit of a district peculiarly adapted to poultry culture, are of necessity numbered among the bygones. Why these things should be we feel ourselves at a loss to account, but certain it now is the generality of our best shows are held exclusively in the northern districts. The Committee at Leigh are, beyond dispute, a worthy example of a number of gentlemen bound each by one firm resolve to use the extreme of personal exertions, and never to rest contented save with the undoubted progress of their special undertaking. Here is the great secret of success—they make it "a long pull, a strong pull, and a pull altogether," there are no divisions among them; they thus obtain public favour, and are of necessity well supported.

The weather, of course, has much to do as regards the receipts at the doors, and this year very unfortunately the day was of the most miserable character—one positive cold and drenching rain. That the receipts were seriously lessened by this mishap is beyond doubt; but that the Show far surpassed in general quality those previously held here is equally certain.

Most of the poultry were of high character, though the adult portion of the classes are as yet far from restored to plumage. Cochins were shown in force, and as a whole were very good. The same may be said of the Spanish, Hamburgs, and Game fowls. It was a matter of congratulation, that those classes most esteemed for table purposes were the best represented; and beyond question, we do not expect to meet with either Geese, Turkeys, Rouen or Aylesbury Ducks of better worth at any of our coming shows. The Grey Call Ducks (several pens being shown), were of decidedly first-rate excellence, and some "domesticated Wild Ducks," were also most commendable.

The wants of the poultry during exhibition were well considered, and had the weather been fine the greatest success must have ensued, besides adding many score pounds of admission money to the finances of the Leigh Committee.

GAME (Black Red).—First, C. W. Brierley, Rhodes House, Middleton, near Manchester. Second, W. Nunnerley, Market Hall, Warrington. **Chickens.**

—First, J. Turner, Stand Lane, Ratcliffe. Second, R. Southern, Welsh Hill. Highly Commended, C. P. Ackers, Bickershaw, near Wigan.

GAME (Any other variety).—First, J. Wood, Moat House, Haigh, Wigan. Second, C. W. Brierley, Middleton, near Manchester. **Chickens**.—First, C. P. Ackers (Brown Red). Second, J. Wood. Highly Commended, C. P. Ackers (Duckwing). Commended, J. Wood.

SPANISH.—First, N. Cooke, Atherton. Second, G. H. Evans, Leigh. **Chickens**.—First, J. W. Speakman, Atherton. Second, N. Cooke. Highly Commended, W. Gregory, Atherton.

COCHIN-CHINA (Any colour).—First, J. Elliott, Westleigh Mill. Second, C. W. Brierley. Highly Commended, E. Smith, Middleton, near Manchester. **Chickens**.—First, R. J. Wood, Lower Crumpsall, near Manchester. Second, G. H. Wheeler, Middleton, near Manchester. Highly Commended, J. Nelson, Heaton Mersey, near Manchester; R. J. Wood. Commended, J. Fryer, Liverpool Road, St. Helens.

BRAHMA POOTRA (Any colour).—First, E. Leech, Greave House, Rochdale. Second, N. Cooke. **Chickens**.—First, E. Leech. Second, J. Elliott. Highly Commended, N. Cooke.

DORKING (Any colour).—First, S. Farrington, Astley. Second, E. Smith. Highly Commended, J. Bullough, Atherton. **Chickens**.—First, J. Bullough. Second, C. W. Brierley. Highly Commended, J. Fryer.

HAMBURGH (Golden-pencilled).—First, J. Turner, Stand Lane, Ratcliffe. Second, no competition. **Chickens**.—First, T. Wrigley, jun., Tonge, Middleton, near Manchester. Second, J. Hazleden, Great Boys, Tyldesley. Highly Commended, J. Hurst, First Lane, Westleigh.

HAMEURGH (Silver-pencilled).—First, E. Crompton, Over Hulton. Second, J. Platt, Deane, near Bolton. **Chickens**.—First, J. Platt. Second, E. Crompton.

HAMBURGE (Golden-spangled).—First, N. Marlor, Denton, near Manchester. Second, G. Whitaker, Horwich, near Bolton. **Chickens**.—First, N. Marlor. Second, G. Whitaker. Highly Commended, J. Gerrard, Brown Street, Bedford.

HAMEURGH (Silver-spangled).—First, J. Hazleden, Great Boys, Tyldesley. Second, J. Wood, Brinscall Hall, Chorley. **Chickens**.—First, J. Hazleden. Second, J. Hurst. Highly Commended, J. Turner, Astley.

POLAND.—First, P. Unsworth, Lowton. Second, S. Farrington, Astley. **Chickens**.—First, H. Smith, jun., Bedford Brewery. Second, P. Unsworth.

POLAND (Any other variety).—First and Second, S. Farrington. **Chickens**.—First and Second, S. Farrington.

GAME BANTAMS (Any variety).—First, G. Green, Back Lane, Westleigh. Second, W. Nunnerley, Market Hall, Warrington. **Chickens**.—First, T. Wakefield, Golborne. Second, H. Kenworthy, Astley.

BANTAMS (Any other variety).—First, C. Walker, West Grove House, Halifax. Second, S. Farrington. Highly Commended, C. W. Brierley, Middleton, near Manchester; J. Mangnall, Adlington, near Chorley. **Chickens**.—First, C. W. Brierley. Second, S. Farrington.

ANY OTHER DISTINCT OR CROSS BREED.—First, C. W. Brierley. Second, J. W. Barlow, Chowbent (Blue Andalusian). Highly Commended, S. Bullough, Howebridge. Commended, J. Gerrard, Brown Street, Bedford. **Chickens**.—First, W. Gillibrand, Tyldesley. Second, no competition.

SINGLE COCKS.

GAME.—First, W. Nunnerley, Market Hall, Warrington. Second, S. Farrington, Astley.

GAME BANTAM.—First, C. W. Brierley. Second, J. Bullough, Atherton.

DUCKS (Aylesbury).—First, E. Leech, Greave House, Rochdale. Second, F. M. Hindle, Bury Road, Haslingden. Highly Commended, F. M. Hindle; E. Leech.

DUCKS (Rouen).—First, E. Leech. Second, J. Nelson, Heaton Mersey, near Manchester. Highly Commended, C. P. Ackers, Bickershaw, near Wigan; J. Bullough, Atherton.

ANY OTHER BREED OR CROSS BREED.—First, J. Bullough. Second, C. P. Ackers. Highly Commended, C. P. Ackers.

GEES (White).—First, J. Southern, Kenyon. Second, L. Walls, Westhoughton. **Goslings**.—First, J. Southern. Second, S. Dornin, Swinton. Highly Commended, L. Walls.

GEES (Coloured).—First, E. Leech. Second, J. Southern. Commended, L. Walls. **Goslings**.—First, J. Southern. Second, withheld.

TURKEYS.—First, E. Leech. Second, C. W. Brierley. Commended, G. Jackson, Bedford Lodge; R. Lansdale, Boothstown.

Mr. Hewitt, of Eden Cottage, Sparkbrook, was the sole Judge.

POULTRY JUDGING.

A FEW days ago I attended a local show, at which a very successful exhibitor residing in the same part of the country as the Judge showed largely, and won in almost every instance. Now in many of the classes in which he won, I am not a judge, but as he is usually successful in them I dare-say he deserved the prizes awarded to him. In one or two classes, however, in which I have had considerable experience, his birds, though winners, were by far the worst in the class; and here a scene took place which I think ought to be made public, and which fully convinced me of the importance of exhibitors knowing before entering who are going to judge their fowls. In a squabble which took place between the Judge and the partner of a large and successful Game exhibitor, the former charged the latter with having on a previous occasion, when he was going to officiate as judge at the same place, sent him the number of every pen of fowls he had entered, with a request that he would do what he could for him. To this the exhibitor replied that the Judge requested him to send them.

Now, whether the exhibitor sent the numbers to the Judge without being requested or not I do not care to inquire, but

it is certain that at the time the two were on good terms, and the numbers were sent and received without any objection; and this proves that unprincipled men get appointed as judges, and inform their friends, and if their fowls are not known numbers are sent.

Let the names of Judges be published, and depend that those who are disposed to act so unfairly will not do so long; exhibitors will then have the remedy in their own hands, and will, of course, cease sending to shows where they are not likely to meet with fair play, and those that are properly conducted and have good judges will be the only ones patronised. Committees of new shows will then be able to select the best and most popular judges, and one of the greatest objections to poultry shows will be removed.—H.

[Our correspondent is known to us, and he has stated the name of the Judge and of the Show. The Judge ought never to be employed again.]

BEWARE OF THE PIG.

UNTIL last night I was under the impression that pigs and poultry, if not sworn friends, were, at least, amicable companions. Such is not the case. Poultry-keepers, beware of the pig! and read this dismal tale. A valuable Cochin pullet of mine entered the pigsty as usual to peck at piggy's trough—she was devoured at once. Nor is this all. The same pig the next day (no doubt with the feelings of a tiger which has once tasted human flesh) in like manner murders and eats whole a Cochin cock. How is it this pig forgets his former friendship with his victims, and now seems determined to eat every fowl within his reach? The comfort is, he will shortly be converted into portly hams, and long sides of bacon, by his injured master—CHANTICLEER.

COMB-PRUNING.

I SHOULD say as a rule, never resort to comb-pruning with the view of rejuvenating old stocks. It is an operation which is likely to do far more harm than good unless performed with very great judgment, and had, therefore, better be altogether let alone. When portions of combs become mouldy or offensive they may, of course, be removed; but even in this case the cure may generally be entrusted to the bees themselves, except when foul brood is present, when an entirely different mode of treatment must be resorted to. Combs will last seven years or more, and I deem it better to break up an old stock at the end of this period than to attempt to renew it by comb-pruning.

The above advice in reply to the question of "C. F. G." in page 224, refers only to hives in which the combs are fixtures; but with either bar or frame-hives the case is very different, and the renewal of brood-comb presents no difficulty whatever. Just about this time, when breeding has ceased in most colonies, a couple of the worst combs may be removed from the centre of a hive with not less than nine bars or frames, and the remaining combs being brought together so as to leave a vacant space on both sides (where empty frames or bars should be inserted), the stock may remain until the spring, when the vacancies at the sides will in due time be filled up by the bees. If the apriarian have not spare combs wherewith to assist them, care must of course be taken that the remaining combs contain a sufficient supply of food, and that drone-combs be not shifted into the "brood-nest." These should be kept at the sides, and if several are present it will, if possible, be advisable to exchange all but one of them for worker-combs. With hives containing less than nine bars it may be best to proceed more gradually by removing only one comb. In either case the operation should be repeated every autumn until all thickened and worn-out combs are done away with.

Judging from my own experience I should be disposed to refer the destruction of the stock, which "had swarmed and cast this year," to the loss of its young queen, which may have occurred from various causes—as, for instance, an accident during her wedding flight, mistaking her domicile on her return, or a regicidal reception by her worker sisters. Combs in which such numbers of bees as are required to

form two swarms had been recently bred, could scarcely have degenerated so suddenly and completely as to account for the entire destruction of the parent stock.

The full-grown drone with pink eyes was probably hatched from what may be termed a chance drone egg—not very unusual occurrence.—A DEVONSHIRE BEE-KEEPER.

YOUR correspondent "C. F. G." wishes for the opinions of other apiarists on the excision or removal of old combs. I shall be happy to give him the results of my own experience. I am convinced that hives, provided they are of good and sufficient internal dimensions, will last much longer than is generally supposed. In 1861 I stocked a number of large ten-framed boxes, chiefly by transferring combs and bees from common cottage-hives. One of these was a swarm of 1857, and the others ranged from that date down to 1860. The original combs, or, at any rate, the majority of them, are still in use, dispersed about my apiary.

In 1858 two straw hives, having flat wooden tops, were tenanted with fine swarms. These hives, known as Nos. 4 and 9, have been among the most remunerative I have ever had. Supers, ranging in weight from 20 lbs. up to 41 lbs., have been afforded by each of these two hives nearly every summer since 1858. One of the hives has, as far as I know, thrown but one, and the other two swarms, during that period. No. 9, after filling a super in the summer, was broken up last autumn, and was full of sealed honey.

Thinking that it might be advisable to change the combs of the other hive, No. 4, I placed under the stock early in the spring a Stewarton-box of beautiful new brood-comb, which had been kept carefully wrapped in paper during the winter. There was full communication, all the spaces between the bars being open. About six weeks afterwards I inspected the interior, hoping to find that the principal part of the breeding had been carried below. On separating the hives I could see that not a single cell in the lower division was occupied by brood, while the upper, which contained the old combs, was crammed with brood down to the bottom. They were replaced just as before, and after another interval of six weeks were again examined. This time there was a small quantity of brood in the lower half, but the majority was still contained in the old combs. Being resolved to wait no longer, I at once drove out the bees from the upper portion, cut out the combs, and placed all the brood in an empty hive on the top of the stock, now reduced to a Stewarton. The brood was in due time hatched out, and these old combs of six years' standing were immediately filled with honey. They have since been removed. I have them still, and they appear as if they would have answered every requisite for years to come. It is also worthy of remark, that, during the entire period, one only of these hives ever had brood in any of the supers, which happened in 1860.

There is another among my hives to which allusion may be made, No. 7, a box adjuster-hive, peopled with a swarm on May 23rd, 1860. In 1861 it threw off two fine swarms, and gave me a large quantity of comb, and 10 lbs. of sealed honey in the super. In the bad year of 1862 it did little more than throw off a swarm. In 1863 I took off from it a beautiful super of 30 lbs.; and this year, 1864, it has filled one of about 40 lbs. The stock-hive is very populous, and I see no reason why it should not thrive for a time longer.

With small-sized common hives there might be more reason to fear the central combs becoming, from age, unfit for breeding purposes, owing to their being comparatively more used, and from the quantity of pollen necessarily stored in them. Had I now such a hive, I should wait for a swarm in the natural course, three weeks after which I should drive out the bees, and break up the stock. If excision of a portion of the combs be resolved upon, it is, as "C. F. G." remarks, of little use cutting out only the side combs. The best time to remove one or two of the centre combs is late in the autumn, after the brood has been all hatched out. The honey may be returned to the bees, and a little feeding may induce comb-building; but if not, the space left between the combs seems to be of little or no injury to the bees, as they will hang there in a dense cluster, thus defying the cold. With frame-hives the renewal of combs becomes a matter of the greatest ease and certainty, which may be carried out at any time. Those who use

these hives scientifically are constantly, during the working season, compelling their bees to make new combs. I frequently slip in a frame of new and clean worker-comb between old combs. This is generally at once taken possession of by the queen, and filled with eggs. "C. F. G." is in error in supposing brood to be so easily chilled. No one would fix on a very cold day in early spring for the operation. In fact I think early spring to be the very worst time that excision, pruning, or removal and substitution of combs, can be carried out. With bar-hives in spring there would be no objection to transposing the outer and the central combs, provided the outer combs were worker and not drone-ceilled, and that the central combs did not contain any brood, for that would almost certainly become abortive. But it is a plan not to be recommended, to say the least of it.

In conclusion, I may state that for some years of my early aparian career I was troubled with the bugbear of old and worn-out combs. With increased experience the causes of apprehension seem marvellously lessened. In both the cases of the hives I have alluded to, I believe the somewhat declining prosperity of the hives to have been due more to the age of the queens than to the age of the combs.

This has been with me a better honey season than the last; but into this I must not now enter, as I intend to relate the results of this year's doings in a separate paper.

—S. BEVAN FOX, Exeter.

RUIN OF A NEWLY-PURCHASED STOCK.

I PURCHASED an old stock-hive about a month since with the assurance that it was a swarm of last year. Can you tell me from the comb I send you if such be the case? Since I have had it I have been surprised to find that the bees have not worked, but have loitered about the alighting-board cleaning each other, although the bees in my other hives are still busy collecting. On the evening of the 7th inst. I took the hive, which is of straw, off the floorboard for the purpose of substituting a clean one. I found the combs black in appearance, but by the little light that there was I failed to discover many bees. Yesterday, on going to look at them, I found that the hive was being robbed by bees from another shed half a dozen yards distant. In the evening I again turned up the hive, the few bees within escaping. I found the combs nearly empty. The hive when I purchased it weighed with the floorboard about 25 lbs. The weight of the floorboard is about $2\frac{1}{2}$ lbs., and of the hive in its present state with nearly empty combs, 12 lbs., so that when I bought it there could have been only about 10 lbs. of bees and food. Probably the queen was dead. Around the edges of the hive, both inside and out where it was sealed to the board, were a great number of white envelopes, each containing a maggot: do these belong to the honey-moth tribe? Will the combs be of any use to swarms in the spring? When should clean floorboards be given? and when and how should stocks be united?—A Novice.

Judging from the appearance of the piece of comb which accompanied your letter, we should say that the age of the stock was correctly stated. Your idea respecting the probable loss of the queen we believe to be right, but the vendor may have known nothing of it, as some of its original inhabitants were probably in possession a month ago. The maggots around the skirts of the hive were doubtless the larvae of some kind of wax moth. We deem the combs rather too old to be given to a swarm. Floorboards should be changed before winter sets in, and in the spring. Mr. Woodbury's articles on driving and uniting bees in Nos. 139 and 144 of THE JOURNAL OF HORTICULTURE will give you the information you require as to the best mode of uniting stocks.]

A FRIEND MISTAKEN FOR AN ENEMY.

AN aparian friend of mine has informed me of an alarming affliction which befell the apiary of a lady of his acquaintance. This lady one day paid a visit to her bees, and was greatly alarmed at seeing one of her hives invaded by a large number of monstrous bees, which were evidently quite masters of the poor honey bees, as they went in and out without hindrance. Not relishing the aspect of affairs, and,

perhaps, fearing that the depredations of the miscreants might be extended to her other hives, she determined to consign this one stock, interlopers and all, to the brimstone-pit without delay. The work of destruction was successfully performed, and the legitimate inmates of the hive, together with their invaders, were consigned to a common death. A few of the latter were carefully collected, and sent in triumph to my friend, who was asked to pronounce his opinion as to what these predators could really be. He found—listen all apiarists who dread the appearance of any new enemy or scourge in your apiaries! he found these terrible enemies were nothing less than the ordinary male bees or drones, and that the too-careful owner had sacrificed her best and most prosperous colony.—S. BEVAN FOX, Exeter.

ARE BEES OMNIVOROUS?

YOUR article from "RUBY," in the Number for the 6th inst., is, I am afraid, likely to mislead new beginners, as bees do not generally sting when swarming, and it is strange his bees do not frequent the borage, as this is considered one of the best bee flowers. My Ligurians were working on it till 7 P.M., the other day, and the plant is generally frequented so much that the country people say they are like swarming, and, therefore, I intend next year to plant a larger extent of it.

You certainly do not mean to say that bees are carnivorous, and I cannot believe that they either eat the bird or the Chinaman's fowl. I believe they would carry out all the flesh from the bones that they could, but not eat it. This story is something like giving Pigeons a salt cat, and as a Welsh correspondent some time since stated, their consuming moist sugar given as you get it from the shop, whereas it is very little of it that they consume, but they carry it out. I might as well state they eat oats, as I put a quantity into the feeder to prevent them drowning, and was rather surprised the next evening to find nearly all the oats gone; and, therefore, the next day I watched them, and was amused to see them very busy bringing the oats out; as they could not carry these sideways they took hold of the thinnest end, and as they came out looked as if they had a long proboscis.

You had better advise "RUBY" to procure Ligurian bees, as they do not sting so much as the black bees, and I can confirm the statement that they gather from red clover after it has been once cut.—A. W.

[Although bees are usually very peaceable when swarming, we regret to say that we speak *feelingly* when we state that even Ligurians will occasionally transgress the strict rule of politeness on these occasions, and we cannot, therefore, feel surprised at a lady declining to run any risk. We have certainly always found bees constant in their attentions to borage when in bloom; but we scarcely know what to say with regard to the carnivorous, or rather omnivorous, propensities attributed to them. We ourselves saw what we doubt not was fruit juice, stored in their cells on one occasion, and we have now before us a letter from the most distinguished hymenopterist in the kingdom, in which he says he has recently observed what to him was "an unusual phase in the habits of the hive bee—a number of bees regaling themselves on the moisture of a putrid bird. The bird had been cut or torn open, was in a state of advanced decay, and a little rain had moistened the stinking mass. On this fluid the bees were regaling themselves." However absurd it may at first sight appear, the fact that bees will pick the bones of small birds when prepared and presented to them in the manner described by "RUBY" is attested by too many witnesses to be entirely discredited. What becomes of the flesh of the poor little biped under these circumstances is rather a puzzling question, but is one that could be readily solved by experiment, if "R. S." or any other of our scientific and observing aparian correspondents, would take the matter in hand.]

"TANGING" SWARMS.

ALTHOUGH the general custom which prevails among country bee-keepers of beating some instrument for the

purpose of inducing bees to settle more quickly, has been violently assailed and condemned by various authors, yet I am by no means convinced that the system of "tanging" is so utterly useless as they would have us believe. Two instances have been related to me which occurred this summer. A labourer was at work in a field, and observing a swarm flying across overhead, he began tanging on some implement, and the bees immediately came down and settled on some docks at his feet, where they remained until he went to the village for a hive. Another man was at work in his garden, when seeing a swarm going away at a great rate, he rapped sonorously on his spade, the bees came straight down, and commenced settling on his person. He was obliged to run for it, to the shelter of a tree. The whole swarm followed him, and clustered on the branches, from which they were hived.

I have proved that the report of a gun will bring down a fly-away swarm. Many years ago I hived a large swarm in a unicomb-hive. At twelve o'clock on the following day the bees suddenly rushed out of the hive, and mounted over some very high trees growing on the old city wall and embankment which separate my garden from that of the bishop's palace. The bees settled in a low bush about fifty yards off from where they started. They were secured and placed in a different hive, and seemed quite contented; but the following day also about twelve o'clock, they again left the hive, and pitched high up among the branches of one of the trees. With great difficulty I brought the swarm down by sawing off a branch, and the bees were hived as before. Fearing they would play me the same trick, I thought of trying the effect of firing a gun, and I was curious to observe the result. Loading my gun with a heavy charge of powder, and placing it within reach, I waited for the next exodus, and it came as I expected, about ten o'clock the following morning, when I happened to be in the garden. A sudden well-known rush and roar, and the air was filled with bees, which gradually massed nearer together, and mounting higher and higher, were already on the point of disappearing over the tops of the trees when I fired. In an instant, quicker than I could have believed possible, down came the entire swarm, and settled within three yards of where I was standing. I suspect in this instance that the violent concussion of the air produced the result, and in tanging, it is probable, that if productive of any effect at all, it is the vibration of the air to which that is to be attributed.

Several other instances have occurred in the course of my aparian career in which the old-fashioned practice of tanging has appeared to have been instrumental in causing swarms to settle quickly, and it seems to me, that after all that has been written and said against the practice, there really is some good ground for the popular idea concerning it.—S. BEVAN FOX, Exeter.

OUR LETTER BOX.

MARKING FOWLS (Fair Play).—Marking with a string or wire round the leg is the mode adopted where Ducks run together in Buckinghamshire, or Turkeys in Cambridgeshire. It is far more effectual to mark in the web of the wing, either with a piece of coloured worsted, or to burn holes with a hot knitting needle. We prefer the latter method, as the marks are never obliterated. They be made thus—

COLOUR OF COCHIN LEGS (Exhibitor).—The legs of all Cochins should be yellow, but there is with them in age a certain change, as becoming grey with the human being. Nothing would excuse blue or green legs, but practised judges and breeders will not look for bright yellow in adults. As well might you expect the bloom and freshness of twenty on the cheek that has been visited by the winds of heaven for fifty years. In fowls, as men, age is the gradual wearing out of vitality, and it shows itself not only in loss of vigour, but the freshness of colour also fades. You must also bear in mind that in all adults this is the season of moulting. All strength and vigour are devoted to the reproduction of plumage—every external is dead or dying. It will help you if we repeat, birds of the year must have yellow legs. There is latitude for adults.

TREATMENT OF A WEAK SWARM (W. J. P.).—If the bees in the strayed swarm are tolerably numerous, all that is necessary is to feed them liberally, and this should be done at once. The best mode of administering the necessary amount of food is by means of an inverted pint bottle, the mouth of which should be tied over with a bit of cap-net, or open canvas, such as is used for wool work, and inverted through an opening in the top of the hive. This bottle should be filled every evening until the nett contents of the hive reach at least 15 lbs.

HONEY DARK-COLOURED (Leighton B.).—The dark colour of your honey this year is owing to some peculiarity of the season, and its effects upon the pasturage. It does not arise from any fault or disease in the bees themselves, nor are you by any means the only one to complain,

WEEKLY CALENDAR.

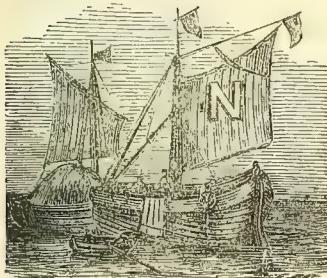

Day of M'nth	Day of Week.	SEPT. 27—OCT. 3, 1864.	Average Temperature near London.			Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.
27	Tu	Ivy flowers.	Day.	Night.	Mean.	Days.	m. h.	m. h.	m. h.	m. h.	m. h.	m. s.	
28	W	Birch turns yellow.	63.2	45.3	55.2	22	56 af 5	46 af 5	22	2	5	26	9 11
29	Th	MICHAELMAS DAY.	64.6	44.8	54.7	20	58	5	26	3	28	27	272
30	F	Beech turns yellow.	65.3	44.9	55.1	24	9	6	28	4	48	28	273
1	S	Horse Chestnut leaves fall.	64.9	43.5	54.2	22	1	6	39	5	32	5	274
2	SUN	19 SUNDAY AFTER TRINITY.	63.6	45.1	54.3	19	3	6	36	5	37	6	275
3	M	Walnut leaves fall.	64.6	44.0	54.3	18	5	6	34	5	41	7	276
			63.9	44.2	54.1	16	6	6	32	5	47	8	277

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 64.6°, and its night temperature 44.5°. The greatest heat was 79° on the 27th, 1832; and the lowest cold, 17°, on the 2nd, 1853. The greatest fall of rain was 1.01 inch.

BULBS.

(Continued from page 229.)

THE NARCISSUS.

EXT to the Hyacinth in point of excellence stands the Narcissus. It requires precisely the same treatment as the Hyacinth, except in two particulars—viz., requiring rather larger pots, and potting right up to the neck. A six-inch or 24-sized pot is the most suitable for single, and 18's for treble bulbs. The best sorts are—

Bazleman major, white, with yellow cup. This is a good forcer, and deliciously perfumed; to my thinking, the best of the Narcissuses.

Double Roman, white. Worthless as usually sent out; but when true, a useful, very early kind.

Grand Monarque, white, with yellow cup; very fine.

States General, creamy white, with yellow cup.

Musat Orientalis, white, with yellow cup, edged with crimson; novel.

Grand Primo, white, with citron cup.

Soleil d'Or, yellow, with orange cup.

Perles Blanches, pure white; fine. Perles d'Amour of some.

Gloriosa, white, with orange cup.

King of the Netherlands (Queen of some), white, with citron cup.

TULIPS.

Very few flowers exceed the brilliancy of colour and the exquisite forms of the early single and double Tulips. The Duc Van Thols bloom about a fortnight earlier than Hyacinths; whilst such kinds as Pottebakker, than which nothing can be more beautiful when in bud and on the point of bursting into flower, bloom at the same time as the Hyacinth.

The varieties are so very numerous that I cannot but give a few of such as I have found the best.

SINGLE TULIPS.

Duc Van Thol, red and yellow; useful on account of its earliness. Scarlet, the best of the Van Thols; very beautiful.

Pottebakker, white; quite charming.

Yellow; good, when not grown in too strong a heat. Red Striped; fine.

Proserpine, velvety rose; a beautiful Tulip, blooming early. Superintendent, white and violet; a good very early kind.

Vermilion Brilliant, glowing scarlet; very fine.

Keizerkroon, golden yellow and red; fine.

Florentine, a yellow, sweet-scented sort, rather out of the common way.

Molière, purple, yellow base; beautiful.

Globe de Rigaud, violet and white; large and fine.

The above are the best for early forcing; but the No. 183.—VOL. VII. NEW SERIES.

following are charming when brought on in a cool house, and make an indispensable show in March—

Grand Duc, bright yellow and crimson; very fine.

Roi Pepin, white, crimson flake; one of the best.

Theba, rose and white; good, but surpassed by Duc de Claremond.

Florida, purplish violet.

Fabiola, rosy violet and white; very beautiful.

Rose Luisante, rosy crimson, peach edges; quite charming. Cottage Maid, rosy pink, bordered with clear white; very pretty.

Berangaria, purplish mauve.

Cramoisie Superbe, crimson.

Bruid van Haarlem, white and red striped.

Lac van Rhyn, violet crimson, white edge, variegated foliage; novel.

DOUBLE TULIPS.

Of double Tulips, which are as yet far short of the standard both in point of numbers and quality, we find—Tournesol, red and yellow; the finest Tulip in cultivation for forcing and general decorative purposes, and a good companion is found in Yellow Tournesol.

Duc Van Thol, red and yellow; well known.

Imperator, crimson; fine.

Rex Rubrorum, bright red.

Gloria Solis, brownish crimson, yellow-edged.

Only half a dozen sorts of double early Tulips! Depend upon it we shall have no more unless growers ask for more good double and fewer single Tulips, which live but a very short time, and are succeeded by others whose only recommendation is novelty.

The soil recommended for Hyacinths suits early Tulips perfectly. The bulbs for early blooming should be potted from the middle of September, and not later than the middle of October; and those required to bloom, say at Christmas, should be potted early in September if possible, the best for that purpose being Duc Van Thols and Pottebakkers. Providing efficient drainage, pot them three in a four-inch pot, five of the early (those for early forcing), in a 24, or if not wanted to bloom before March, in 18's, placing the bulbs deep enough in the soil to be just covered. After potting give a good watering, and plunge in coal ashes or spent tan not deeper than is sufficient to hide the pots, the bottom on which the ashes are placed having been made impervious to worms. The pots should remain there for a month or six weeks (not longer), and be protected from heavy dashing rains and frost, but fully exposed at other times. After this wash the pots, clean the surface soil, and place in a cool house from which frost is merely excluded, keeping them near the glass, fresh air being admitted whenever the thermometer is above 32°. Tulips cannot have too much light and air. Under glass they will require watering occasionally, for the soil should never be allowed to become too dry, and a good supply should be given when necessary. Kept in this way they will bloom in March; but when an early bloom is desired some of them should be introduced into a house with a night temperature of 50°, and treated in precisely the same way as advised for Hyacinths, keeping them in heat until the flower is

No. 835.—VOL. XXXII., OLD SERIES.

visible, when they should be removed to a house with a temperature of from 45° to 50°. In this stage advantage may be taken to apply liquid manure at every alternate watering, which will improve the substance of petal, and I think the colours are brighter. Care, however, should be taken not to apply it too strong. I find fresh cow and sheep-dung, a peck of each put in about 70 gallons of rain water, make a liquid quite strong enough for the Tulip. At other times the Tulip should be supplied with clear water only; and it should be borne in mind that liquid manure will not do any good unless the plants receive fresh air, and all the light practicable by close proximity to the glass, which is the secret in growing large flowers on short stout footstalks, and in giving brilliancy of colour. In a strong heat and at a distance from the glass they become drawn, and are incapable of supporting the blooms, and staking them to keep the head erect is anything but sightly.

CROCUSES.

I was much pleased at seeing a lovely Crocus to-day (September 9th) peeping from its lowly bed. I will say something about autumn-flowering Crocuses in due time; but at present I will treat of those most suitable for growing in pots, sand, &c., and in water.

Prince Albert, purple; pure and decided.	New Giant Yellow, a splendid yellow Grande Vidette, fine blue.
Queen Victoria, pure white.	Sir Walter Scott, large; white and blue striped.
Ne Plus Ultra, large blue. A great advance.	Versicolor, striped.
La Majestueuse, large; striped.	Maria Stuart, white.
Bride of Lammermoor, striped.	Lord Byron, bright blue.
Albion, immense blooms; white and blue striped.	Elfride, white.
David Rizzio, dark purple.	Bride of Abydos, pure white.
	Lilaceus superbus, a good lilac.

Crocuses like the same soil as Hyacinths, and should be potted five in a six-inch pot, placing them about half an inch below the surface, and plunging the pots in the same manner as directed for early Tulips. They are to remain plunged until the foliage appears above the plunging material, when the pots are to be freed of dirt, and placed in a cold frame, protection being given from frost and heavy rains, but full exposure at other times. Keep the pots there until the beginning of December, when they may be placed on a shelf in the greenhouse, where abundance of air should be afforded; and if kept well supplied with water the bulbs will bloom finely in due time, usually about a month before those in the open ground.

If required to bloom at Christmas, Crocuses should be removed from the plunging material by the 1st of November, and be placed on a shelf in a cool greenhouse, as close to the glass as possible without actually touching it; and if fresh air pass over them continually they will show how grateful it is to them by the thickness of the rising bud and the shortness of the foliage. In the last week in November remove them to a warm greenhouse, with a night temperature of 45°, taking care to avoid the usual causes of blindness—viz., great distance from the glass or light, and a high temperature with but little air. Water freely, but not until it is wanted, and in a fortnight or so place in a temperature of 50°, and supply with weak liquid manure, affording them a light and airy situation. Nothing is so pernicious to the Crocus as confined air with a strong heat. When highly excited the flowers perish in the sheath, and the foliage grows at a rapid rate. If the pots are removed to a house with a temperature of from 40° to 45° when the blooms are about half expanded, these will last much longer in beauty.

For growing in glasses select the largest and most healthy-looking bulbs. Place a lump of charcoal about the size of a walnut in the glass, and fill up the glass to within a very little of the base of the bulb with rain or pond water. Set the glasses in a cool dark place for a month, and then expose to light. The most suitable position is the window of a cool room facing the south, placing them quite close to the glass, and where a little fresh air can be admitted in mild weather. The glass should be kept filled to within half an inch of the base of the bulb as the water is exhausted by the plant or evaporates, letting it remain in the room twenty-four hours before it is put into the glasses. With this treatment the bulbs will bloom well, but by no means equal to those in soil. If kept in a warm room in a dark place, at a distance from the glass, and without air, they will not bloom at all, but produce an exuberant mass of foliage. Crocuses in

water are not adapted for forcing, but should be allowed to bloom gradually, the heat of a living-room or sitting-room being quite warm enough; and even there they must be kept near the glass and be turned round daily, placing opposite points to the light, or they will become one-sided.

To grow Crocuses in moss or sand in the form of pyramids, and in a variety of vessels, place a layer of moss at the bottom of the vessel, and fill it to within an inch of the intended surface with sand, if this is the material to be employed, or fill with moss, pressing it tightly; then place the bulbs about 2 inches apart on the surface, and just cover them with sand or moss as the case may be. Give a good watering, and set in a cool place. When the buds appear remove to a cool window, watering them occasionally so as to keep the soil thoroughly moist. Kept in a light, airy, cool situation, they will bloom in due time; and whatever heat they are subjected to it must be given gradually, for the Crocus of all bulbs is the most impatient of forcing. The essentials to success are close proximity to the glass, fresh air daily, pots full of roots, and a temperature not exceeding 50° by fire heat. For early blooming they should be potted early in September; and for succession, generally at intervals of a fortnight until November.

JONQUILS.

Their fragrance is their chief attraction. They require the same treatment as other kinds of Narcissus. I usually place five bulbs in an 18-sized pot, covering them with soil to the neck, placing them in ashes out of doors, and otherwise treating them as the Polyanthus Narcissus. Unless the blooms are wanted early, when they should be forwarded as recommended for Hyacinths, it is not advisable to force them much before the days lengthen, otherwise the foliage is long and the flower-stems weak. The large double do very well in water in Crocus-glasses, if afforded the same treatment as Hyacinths. The single are very sweet, and admirably adapted for pot culture.

THE SNOWDROP.

This is occasionally forced, but it comes in at such an early period naturally, as to leave little to be desired or gained by doing so. Where they are desired, some strong bulbs should be taken from the open ground, potted early in August, and plunged in coal ashes in a cold frame. In November remove to a cool greenhouse, and place on a shelf near the glass, where they will need copious supplies of water, and air on all favourable occasions. They should not be introduced into a temperature exceeding 45° until the flower-buds show. Any description of loamy soil suits them.

IRIS.

Of these the most suitable are the Peacock Iris (*Iris pavonia*), and the Persian Iris (*Iris persica*). *Iris susiana* is very distinct. They should be planted early, three to five in the size of pot large enough to hold them without touching each other. Having filled the pot three parts full put in the roots, cover with soil to within half an inch of the rim of the pot, and place in a cold frame. It is desirable to have the soil in a moist state, so that no water may be necessary until the growth appears. They should be protected from frost and heavy rains. If required to bloom early they may be removed to a cool, light, airy situation in the greenhouse. They are rather impatient of heat, and will only endure a moderate amount of forcing. They should be watered rather sparingly at first, increasing the quantity with the increased growth of foliage. The heat of a warm greenhouse is sufficient forcing at any time, and this should not be given until the foliage is somewhat advanced, and it must then be accompanied with abundance of fresh air.

IXIAS AND SPARAXIS.

The soil most suitable for these is light turf loam one-half, leaf mould one-fourth, and peat one-fourth, with a free admixture of sand. Drain a 24-sized or six-inch pot to one-third its depth, and then fill with compost, placing five roots about 1 inch below the surface. Place in a cold frame, protecting from frost and heavy rains until the pots are filled with roots, when they may be set on shelves in the greenhouse, water being duly supplied, air admitted daily, and no more heat given than is necessary to exclude frost. Water freely as the plants advance towards a flowering

state, but when the blooming is over gradually reduce the supply, and when the foliage is quite gone remove to a dry place until the time of repotting, which is the latter part of September or beginning of October. They should not be disturbed, for by keeping them in the soil when at rest they retain their firmness much better, and flower much more vigorously. In potting the balls of earth should be carefully broken, and the old soil and offsets removed.

There are many more bulbs that are worth cultivating, but these are not such as are usually purchased annually, and grown in pots or otherwise for winter decoration. I shall continue to treat of many others occasionally in future Numbers, but must at present defer any remarks on them, giving preference to those bulbs and plants employed for the decoration of the flower garden in the early spring and summer months.

G. ABBEY.

MY ORCHARD-HOUSE.—No. 10.

"IN terrorum (*sic!*) over mortals," So says Mr. Spurgeon in one of his sermons, and so may amateurs say of these papers, which already number ten. Judging, however, from the communications received the interest is not quite abated; and here let me continue the list of a few fruits which were omitted in my last paper. This part of the subject seems to me of the utmost value; because, if orchard-houses do really gradually advance the period of maturity in fruits, this is a great advantage. I am satisfied, however, that this ordinarily takes place after the lapse of a few seasons—that is, that the trees take a certain time to accommodate themselves to their new conditions of life: therefore, it would not be proper to look for this in houses newly stocked. To give an example. The De Milan Apricot was, when I first had it, only ripe in the beginning of August. This was seven or eight years ago. It then by being continually placed in the very warmest part of a warm but unheated lean-to, enjoying the advantages of long and mild autumns, and of moderately cold winters, and being closely summer-pruned, which Mr. Rivers says is one cause of his success with Apricots—it then rapidly advanced through July, till it has reached the 20th of June, ripening at that date. I have not heard of anything so early in England or in these islands. But this is the only one which is so early, though De Coulange, an excellent kind, is only a week later and more prolific. We have not here Mr. Rivers's earliest kinds, De Sardaigne and D'Oulins, and cannot, therefore, compare them under the same conditions.

The Kaisha Apricot, on the other hand, has not done well with us. I have only one tree of it, which is a large espalier. It is stationary, and ripened on the 30th of July; Peach Apricot on the 16th of July. All our really valuable kinds are ripe in July. When August comes the open walls furnish us with Royal George (the best grown in the islands), Grosse Mignonne, a few Red Magdalen, and still fewer late Peaches; but here, as in England, these must be uncertain. Why not confine ourselves to early and free-growing sorts when there is any doubt about it?

As to Nectarines, here they are not much grown, for the excellent reason that they rarely ripen. They will not succeed in low sandy peat districts here, which suit Apricots pretty well in good years, and these districts are in the very warmest parts of the islands, and produce early Potatoes from two to three weeks before the upper ground.

Out-door Grapes are a failure. Figs ripen well. Standard Pears succeed if hardy sorts, and only free-bearing are selected. Our best Pears, such as Chaumontel and Beurre Superfin, are invariably grown on walls with a good aspect. Plums do well, but then, in these as in most fruits, only the well-known kinds are cultivated. Apples do very well generally. Thus much to show our climate. Jersey, however, has a higher summer temperature, our island being more enveloped in clouds, and is better adapted for fruit culture. The orchard-houses built and building ought to do remarkably well there. I am afraid, as here, that gardeners able to work them are wanting.

In the orchard-house, then, the July Peaches and Nectarines and the June Apricots are of great value, especially if they continue to advance. We thus compete with heated houses in England, and out-door fruit from Lisbon and

Algiers. But the August fruits in the house, except the very early ones in that month, though most valuable as succession for home consumption, rapidly decline in market value. Having these on the open wall we exclude them from the house. This may prove an error, because if a Royal George could, by acclimatising itself to the house temperature, gradually become a July Peach, without losing size or colour, it would be much esteemed by our critical friends the dealers—*i.e.*, they would find a public ready to appreciate their efforts to please.

The September Peaches in the house are of very little importance, even for home use. At that time the novelty of Peach consumption is somewhat dulled, and Plums out of doors, besides Grapes from the vineyards, seriously compete with Peaches then. One of the best of our September Peaches is Shanghae; it is large, well coloured, and sweet. It was ripe on the 10th of September this year, last year on the 11th, and the year before on the 16th. In time it will be valueless to me, and become a late August Peach, just contemporary with the main crop of Grosse Mignonne. Admirable Jaune, that staple of the Angers market, is not easy to ripen without being woolly. It is an October Peach at Angers, but here was ripe on the 12th, 10th, 10th, and 5th of September, during the last four years. Next year it may be a worthless August Peach.

But the fact remains that orchard-houses, after being worked a few years, will generally advance the ripening of fruits. The best kinds appear to gain the most. We may also reasonably hope that no fruit so advanced will recede; none of mine have, out of seventy varieties, and from one to twelve of each variety. No doubt it would be best that tropical fruits, and very delicate sorts of American Plums, Cherries, and Apples should pass a season or two in some intermediate orchard-house in a warm climate before being generally tried in England. A part of our house is planked for a promenade. This is cheap to construct, warm and dry for the feet, and adds to the general warmth of the house.

All our trees have been top-dressed since the middle of September. Most of them are pruned. Some have been changed into larger pots, and unless this is carefully done the check to the vitality of the tree is evident. We also allowed, during cloudy weather, the roots of trees from which the exhausted soil had been removed, to remain without renewing the soil for some days. The object was to hasten their rest; but it is a hazardous operation. I am sure, however, that if one portion of the tree has become disproportionately larger than the other portion, to bare the roots of that side for some time at this season would tend a little to check growth.

Now is the time to begin to prune the trees; but not all at once. Begin with removing, with sharp scissors, the dead shoots; then those drying up; then straggling shoots; then those bearing too far from the leaders. After this cut out the sturdy shoots, often not half ripe, and often tending inward; then shorten the bearing shoots, generally to a triple bud. Open the centres, shorten the leaders, but not at once. Leave something for the spring. The forms of the trees are very important considerations for future notice; also the arrangement and classification of the sorts, so as to save room.

Being about to re-arrange the front ventilators, which swing on central pivots, I should be thankful for suggestions as to the best and cheapest way of effecting this. These hints might be recorded for the benefit of others, and so all would gain.—T. COLLINGS BRÉHAUT, *Richmond House, Guernsey.*

REFORCING STRAWBERRY PLANTS.

HAVING forced some Keens' Seedling Strawberry plants this season, and very few of them having had fruit on them, will you say if these plants will do to force again? They have been outside since June. They are in No. 12-pots, and are full of foliage.—A CONSTANT SUBSCRIBER.

[If your Strawberry plants that did little good this season, and are in 12-sized pots, now full of fine foliage, have been full in the sun since June, and the pots are full of roots right through, making the ball as firm pretty well as a Dutch cheese, and you lay them on their broadside by the end of the month to stop growth, then we think you will

get plenty of fruit the next spring. If your plants, now full of foliage in these tremendous pots, have been kept partly or wholly in a shady place, then we would expect to have more fruit from our little compact plants in what are called 40-sized pots—that is, between 48's and 32's. There is a great fallacy in supposing that mere size of pots and luxuriance of foliage will yield so much fruit in forcing.]

ORCHARD-HOUSES VERSUS WALLS.

SOMETIMES at a friend's house I get a look at your interesting paper, and during the last few months I observed that a controversy was going on respecting orchard-houses, and it appeared to me that the defenders of the orchard-house system, from some cause or other, did not make a very good defence. I felt very much inclined to enter into the battle, but I was much engaged, and in addition to this, I wished to have the results of another year's trial to strengthen me in my opinions. What those opinions are I will state presently.

I think I gathered from some of the letters which I read, that walls were far preferable to orchard-houses, and that better fruit could be obtained from a wall than from an orchard-house. My own experience is directly opposed to this, and I now have the results of two horticultural shows to back up my own previously-formed opinion. Remember, I do not say that good fruit cannot be grown on a wall, I know it can; but I maintain that, as a rule, an orchard-house will produce handsomer and better-flavoured Peaches and Nectarines than a wall.

Mr. Rivers has been a great benefactor to the public, and speaking for myself I can candidly confess that he has opened out to me a most delightful amusement. The only thing I blame him for, is for not strictly limiting the fruit to be grown on the trees in 11 or 13-inch pots to a dozen and a half at the very utmost. I consider that the following sentence has done more harm to the system than anything that ever was written by an opponent: "The third year a tree, if it has prospered, will be able to bring three dozen to maturity; it is, however, better to have a few finely-grown fruit than many that are small." What errors have those few words led me into! How I have overcropped! and there are hundreds of other persons still doing the same, and growing a lot of small, trumpery fruit, far inferior to wall fruit, and scarcely fit to eat, and it is no wonder that it should be boldly stated that walls will beat orchard-houses.

I do not like being egotistical, but to make my letter say what I want it to say, I must speak chiefly of my own experience. Six or seven years ago I knew nothing of fruit trees, I did not even understand that a Peach tree always bore on the new wood. I was ignorant of everything. I bought Mr. Rivers's book; I built a small orchard-house; I potted, pruned, syringed, and watered my own trees, and this year I have ended my season by taking five out of eight prizes at a horticultural show held in a town justly celebrated for its fruit. Half the first prizes went to the wall fruit, the other half to orchard-house fruit; all the second prizes to orchard-house fruit.

Again, I attended another show a few weeks ago, and there out of the four prizes for Peaches and Nectarines, only one went to out-door fruit, the other three to orchard-house fruit. Going back to last year, all the prizes at a show at which I was present went to orchard-house fruit, with the exception of one which was taken by a dish grown on a trellis in a regular Peach-house. Thus you see that my own experience and observation convince me that better fruit can be grown in an orchard-house than on a wall. I mean speaking generally. Of course, wall fruit will sometimes be very fine and good, but with proper cultivation, orchard-house fruit must be good.

I will just relate what happened to me at the show to which I first alluded. I was placing my fruit on the table, and a gentleman near me asked me where I had grown it. I said in a rough-boarded orchard-house. "Well, then," he replied, "they are of no use. I tried to grow some, but could get nothing worth having." "Well," I said, "if you did not, it must have been your own fault." Holding up a dish of beautiful Peaches the gentleman said, "These will beat yours;" but, he added, "They will all be tasted, and the best

will win." Returning to the show in the afternoon, I found that I had beaten my friend, but I was in turn beaten by a splendid dish of out-door fruit. Still I took one first prize for Nectarines, and all the second prizes. In fact, no less than five out of eight prizes went to fruit grown in my little, rough, twenty-feet orchard-house.

The simple reason why people do not succeed with orchard-houses is that they overcrop, and do not give enough air and water. Let it be plainly stated, that a small tree three or four years old ought not to have more than ten fruit on it, and never more than two dozen, and we shall hear no more about orchard-house fruit being inferior to wall fruit. I will admit that a tree will grow three or even four dozen fruit, but it must be of inferior flavour, and the tree will refuse to do anything during the next year. I could write a good deal more on the subject, but I must not take up any more of your valuable space.—A POOR GENTLEMAN.

EXHIBITING GLADIOLI.

AN observation made by your reporter concerning the stands of Gladioli exhibited by Mr. Kelway at the Crystal Palace induces me to say a few words on this mooted question, which resolves itself into these points—Are they to be exhibited with any foliage? and if so, with what kind?

I have seen them shown with their own leaves, with fronds of Fern, with Canna leaves, and with Yucca leaves. Of all these I think their own leaves the most effective; but then it is objected that this gives an unnatural idea of the habit of the plant, as if its flower were produced amongst the leaves instead of being thrown well above them, as we know them to be.

This is true enough; but still, as everybody knows how they do grow it is not a very valid objection.

Fern leaves and Canna leaves with Gladioli flowers are failures, and Yucca leaves worse still. They are unfair, and for this reason: There are, it is well known, two distinct strains of Gladioli—those which, having more of the *Gandavensis* blood in them, show the spike on one face; and those of the *oppositiflorus* type, an inferior class, where blooms are produced on either side of the stalk. Now the Yucca leaves, being very strong and slightly concave, have the effect, especially when they are placed in pots and thereby made stiffer still, of throwing this latter class of flowers forward, consequently of giving them the appearance of also being grown with one face. Especially is this the case when the spikes are stitched in to the Yucca leaves, and so kept in their place.

I am not sure, after all, whether it would not be well to adopt the rule with regard to other florists' flowers, and let them be shown as they are grown, without the addition of any foliage.

I heard some one say, looking at Mr. Standish's noble collection, "There's the disease and no mistake!" whereas the foliage was all cut from one sort, Fanny Rouget, in which there is this shade of yellow.

Here let me say for the encouragement of those who are afraid to venture on them, that I have had no disease amongst mine, and that I attribute this in a great measure to thoroughly drying the bulbs. I shall shortly cut down all the stalks to about a foot, and then cover the bed with old Cucumber-lights, and when I get it tolerably dry take up the bulbs and then thoroughly dry them. This I believe to be the secret.—D., Deal.

THE VINE IN CANADA.—The partial failure of the Wheat crop, recurring every year, is beginning to produce a conviction that we have been too much in the habit of depending upon this crop. Many farmers are betaking themselves to the resource of Flax cultivation, for which, beyond all doubt, our soil and climate are well adapted. Grape culture has not hitherto been looked upon as a pursuit which could be followed in Canada with advantage. But if we may trust the evidence produced before a select Committee of the House, appointed last Session, to inquire into the subject of Vine cultivation in Canada, we must revise our former notions in regard to it. The Committee bring out the fact that there was an application from M. de Courtenay to the Govern-

ment in 1859, for assistance to enable him to demonstrate, by practical experience, that the climate of Canada is peculiarly adapted to the successful cultivation of the Vine. The opinion was in the first instance founded on the authority of Count de Gasperin, that for Grape culture the "climates most favourable are those where the duration of the season of vegetation is shortest, and where, in such season, the total heat is the highest; where the difference between the solar heat and the minimum heat is the greatest, and where, consequently, vegetation proceeds by shocks and not by a uniform march." M. de Courtenay stated to the Committee that his experiments have been successful both with the wild Vine of the country and with several delicate varieties of European Vines, and that these adapt themselves without difficulty to the rigour of the climate; and he has manufactured good sound wines from these Grapes. Mr. Justice Day cautiously certifies that the wine "is of a quality to justify confidence in a high degree of ultimate success." Chief Justice Drummond, after testing two kinds of it, pronounces "one of them especially superior to the *vins ordinaires* of France." Mr. W. J. Brickle, of Quebec, who has been in the wine trade for years, affirms that the native wine in question "is such as would be of high marketable value in any country." Mr. Lemoine, more enthusiastic, pronounces it "delicious," and another witness assures the Committee that it would have been "pronounced good in any wine-producing country." This enterprise is to be prosecuted both in Upper and Lower Canada, and also the cultivation of the Mulberry, and we heartily wish success to the undertaking. (*Toronto Leader.*)

ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE, September 13th.—At this meeting many interesting plants and flowers were exhibited, seedling Dahlias prevailing. There were many good ones among them, but very few of extraordinary merit. Mr. Salter, Hammersmith, brought plants of a new variety of *Cineraria maritima*, named compacta, of dwarf habit, but the foliage not so white as with the old well-known kind; scarlet *Pelargonium multiflorum*, a semi-Nosegay, with bright scarlet flowers and zonate foliage, but there were not sufficient trusses to test its merits; and scarlet *Pelargonium Crimson Mantle*, a Nosegay, with crimson flowers shaded with rosy purple.

Mr. Turner, Slough, sent seedling Dahlia Leah, deep golden yellow tipped with rose, exquisite form, and in every respect a first-rate flower—first-class certificate; and Dahlia Miss Roberts, deep lilac rose, rather too flat, and inclined to be coarse, the colour was the great recommendation—second-class certificate. Mr. Rawlings exhibited several seedling Dahlias. Spitfire, a dull red, of good form, a promising flower, had a second-class certificate. The other seedlings were not thought worthy of distinction—viz., Queen Victoria, Exquisite, Sparkler, Modesty, Mr. Sladden, Constancy, Prince, Mrs. Sladden, and Humility. Mr. Pope, Chelsea, had seedling Dahlia Walter Newman; and Mr. Legge, Edmonton, seedling Dahlias Mr. Golding, Ellen, Crimson Perfection, Beautiful, Royalty, Glory, and Excellent, none of which were thought worthy of a certificate.

Mr. Perkins, Coventry, exhibited seedling *Verbena Shakespeare*, scarlet, like Lord Leigh and Foxhunter a very fine flower. Mr. Saltmarsh brought several seedling *Pelargoniums* with highly coloured and variegated foliage, much resembling Mrs. Pollock and Sunset. One called Meteor seemed rather in advance of the others. It is equal to Mrs. Pollock, of good habit, the zonale markings distinct and beautiful. It is a variety well worth growing. A plant of Mrs. Pollock was sent for comparison, but it was a sad specimen of that truly exquisite kind. Sunrise, with highly-coloured foliage, was also good. The others were Luna, Hon. Mrs. Mildmay, too much like Mrs. Milford, and Admiration, a pleasing white variegated-leaved variety with crimson zone, but inferior to the beautiful Italia Unita. Little Treasure, a free-flowering dwarf variety, with scarlet flowers, like Tom Thumb, of very compact habit, producing a profusion of trusses of flower, and very useful for bedding purposes, received a first-class certificate. Mr. Cooling, of Bath, again exhibited his beautiful striped *Verbena Annie*, it now re-

ceived a first-class certificate, having secured a second on a previous occasion. It is a very pretty variety.

Mr. Bull, Chelsea, exhibited *Caladium splendidissimum*; the plants sent had but one leaf each. It is a promising kind; and the immense leaf of pale green being richly stained in its centre with deep rosy crimson, renders the plant very attractive. There is little doubt that it will take a good position among other *Caladiums* when grown stronger. The Committee requested that it might be sent again. *Gesnera Chromatella*, also from Mr. Bull, producing a pale golden flower, with dark velvety foliage of green and black, received a second-class certificate. He likewise contributed a weak plant of *Saccolabium Dayii*, not in condition; a pale variety of *Lilium auratum*, *Lilium lancifolium densum*, reflexing its bright rosy petals, and producing a good head of flowers; Dahlia Gem of the Dwarfs, flowering in 60-pots (the flower was bad and out of character); *Petunia Rigollette*, purple shaded with white on a pale purple ground; and double *Antirrhinums General Manara* and *Guiseppi Garibaldi*. The latter was awarded a label of commendation. We doubt whether these double varieties will be very useful, they have a ragged and untidy appearance not unlike a faded semi-double German Wallflower. From the same exhibitor came also *Pentstemon Conquest*, deep marked throat, with four others; and *Aucuba japonica vera*, with berries, a plant of which received a first-class certificate when shown by Mr. Standish at one of the spring meetings.

Messrs. Downie, Laird, & Laing sent two seedling *Pentstemons*, and Mr. Parsons, gardener to W. J. Blake, Esq., Welwyn, four seedling *Achimenes—Aurora*, a perfect gem with its superb finely-formed bright rosy carmine flowers—first-class certificate; Rose Queen, deep purplish rose, fine broad flower—first-class certificate. From Mr. Burgess, Chelsea, came *Dahlia George Griswold*, and from Mr. Tillary, Welbeck, a box of seedling Hollyhocks, the flowers produced on plants raised from seed sown in February, 1864; also four seedling Dahlias, which, having sustained much injury in the journey, could not be examined. The seedling Hollyhocks were many of them very good varieties. Mr. Wm. Paul brought cut flowers of his seedling Roses, Dr. Lindley, and Rose globosa, proving their character as Perpetuals.

The **FRUIT COMMITTEE** did not meet on this day. Mr. Bousie, gardener to Lord Taunton, Stoke Park, sent three bunches of white seedling Grapes, which were unripe; Mr. Wm. Paul two bunches of a very superior seedling Grape of the Hamburgh class, with rich Frontignan flavour; and Messrs. Lee, Hammersmith, a seedling yellow Plum somewhat similar in character to Coe's Golden Drop.

FLORAL COMMITTEE, September 19th.—A meeting of the Floral Committee took place at the Society's gardens, Chiswick, this day, at which the majority of its members were present. It was intended to have included *Verbenas*, *Petunias*, &c., among the plants for examination, but the extensive collection of scarlet *Pelargoniums* alone occupied the whole attention of the Committee. It was most satisfactory to hear from every member present an approval of the new arrangement of the trial plants, which, however imperfect this present season, will, we trust, from several useful suggestions made, be greatly improved next year; and when we consider the delay in making these new beds which proceeded from the reluctance on the part of the Council to attend to a letter addressed to them on this subject by the Floral Committee, and the very late period at which many of the trial plants were sent to the gardens, as well as the unusually dry season the plants have had to contend against, we may congratulate those interested in this matter that so much of great interest is to be seen in the old gardens.

It was difficult in many cases to decide the merits of some varieties which had not attained their usual vigour or character of habit, but a great number received their respective marks of estimation, a list of which we shall furnish at some future time. The plants marked **xx** were considered worthy of a first-class certificate, those marked **xx** meriting a second-class certificate. We cannot refrain from observing how very injudicious it was to invite the public to examine these trial plants before the Floral Committee had passed judgment upon them. Who is to blame for this we do not stop to inquire, but it is very evident that whenever any attempt is made to carry out some practical point in horticulture, it is certain to be marred by the ill-

judgment of some prevailing influence. Encouragement to those who willingly give their time and labour to this work is never or sparingly given, but too often discouragement follows their exertions. We would advise those who are interested in the scarlet Pelargoniums to lose no time in making their notes for another year, and to inspect the extensive collection now in perfection at Chiswick; but we would add this caution, be it remembered, that not every scarlet Pelargonium is of necessity a bedding-out plant, nor suitable for this purpose. It is a general and too common mistake made, that all scarlet Pelargoniums are bedding-out plants. Many of them, scarlets as well as the more delicate-coloured varieties, will never be seen to perfection unless grown in pots under glass, and protected from the sun, rain, and wind. As a proof of the justice of this remark, let a visit be paid to the greenhouse in the fruit garden at Chiswick, where many of Messrs. Bull's, Van Houtte's, and Salter's most exquisite varieties may be seen in the greatest beauty and perfection.

LIVERPOOL BOTANIC GARDENS, 1863.

In an article which appeared a few weeks ago, my respected coadjutor, Mr. Fish, alluded in terms of great admiration to the manner in which these gardens were kept last year, and I was in hopes that we would have had from him one of those lucid descriptions which have made the readers of THE JOURNAL OF HORTICULTURE so well acquainted with places of note, both in this country and in the Sister Isle. It is probable, however, that he may have had the advantage of seeing this fine place in the present season, and may, therefore, intend to give us a later account of it; but should this be the case, the few remarks which I am about to make as to its appearance in 1863 may nevertheless, be interesting, as showing the then state of this garden.

Before I proceed further with the subject of botanic gardens, I may remark that the one here alluded to has more claim to that name than many to which the term is applied. The science of botany, however much the fact may be regretted, is certainly not a popular science, for it is probable that the number who studied it thirty years ago was as great as it is at the present time. In the Liverpool Botanic Garden botany is cultivated in the manner most likely to gain the favour of those who have not the means, nor, perhaps, the inclination to pursue botanical researches to any great extent. Botany and floriculture are agreeably and judiciously combined, and the students in each department have each their lesson, and a neutral ground on which to meet and discuss progress. In no place to which I have been has more variety in the flower garden ornamentation been brought together, and nowhere was more taste shown or care taken in the management of the plants employed.

The Botanic Garden of Liverpool is situated on a rising ground to the north-east of the town. It is sufficiently near to be at all times accessible, and not too near to suffer much from the smoke, which in every large town is an obstacle to good cultivation. The approach is by one of those wide open streets which radiate from a central point to some place in the suburbs. Suitable and convenient gates admit the visitor into the garden, which is open to the public without charge. This advantage contrasts favourably with the plan adopted at some other places, where considerable difficulty is met with in gaining admittance, or where a heavy charge is made. The grounds extend over several acres. The outer wall is covered with creepers, and in certain places is used for training shrubs or plants not generally esteemed hardy. A range of plant-houses occupies the northern side of the ground, with some sheds and other necessary offices behind. The ground elsewhere is divided by belts of shrubs or trees marking out by irregular and pleasing outlines, several divisions, which are planted in various ways. Some contain groups of plants having a botanical affinity to each other; others a mixture of such plants with some of the popular bedding plants of the day; while some compartments are devoted to showy plants alone. In many instances the latter were intermixed with plants not often employed for ornamental purposes, and I took a few notes at the time of such as struck me as the most deserving of attention. I will not attempt to describe the series of beds of which those noted

formed a part, but will simply state what were remarkable, making at the same time such comments as seemed to strike me as necessary.

A long bed planted in stripes or ribbon fashion, had a row of *Calceolaria amplexicaulis* in the centre, a row of dark *Calceolarias* on each side, then a row of *Geranium Tom Thumb*, and finally an edging on one side of *Stachys lanata*, and on the other *Antennaria gnaphalioides*, the last named being a plant by no means to be despised.

Two scroll beds were each *Verbena*, one being a good scarlet and white mixed, and the other purple and white mixed, the latter being the most telling. Both beds were edged with *Cerastium*.

A large circular bed was planted entirely with blue *Lobelia* and *Cerastium*, the latter forming the ground, the *Lobelia* being arranged in four heart-shaped figures meeting in the centre; and intervening between them were four knots of the same near the outer edge. This was a very effective bed, much better than if it had been loaded with more colours. I may also state that another circular bed, having a tree in the centre, had a broad band of blue *Lobelia* around it at the distance of 4 feet from the collar, and on each side of that band was a single line of *Cerastium*; this was also effective, blue and white being in general the most telling colours.

Another circular bed was *Alma Geranium* and the dark-leaved *Trifolium*, usually called the Irish Shamrock, mixed. The combination looked pretty well; but the bed would have been better with an edging of *Cerastium*. A similar bed to the last had *Geranium Golden Chain* instead of *Alma*; this also looked well. A circular bed of considerable size had an inner circle of Scarlet *Geranium*. The outside ring, about 4 feet wide, was planted in wedge-shaped panels, alternately blue *Lobelia* and Variegated *Alyssum*; this looked well. Another bed of *Perilla* and double *Pyrethrums* mixed, with an edging of *Cerastium*, likewise looked well. A bed of a more permanent kind was *Aucuba japonica* mixed with a *Delphinium*, a ring of *Ivy* going round the *Aucuba*, the whole being edged with *Stachys lanata*. This bed was very good, and doubtless lasting.

Amongst other beds I noticed a general use of dwarf *Dahlias*, with some *Ageratums*, and other popular flowering plants, while for an edging the neat-habited *Antennaria varicata* was introduced with good effect, though perhaps not better than the Variegated *Veronica*, which was also used. A rather pretty *Oxalis* called *rosea*, said to be an annual, looked well at the time I saw it, and a yellow *Pansy* deserved more general cultivation. Several other hardy herbaceous plants were brought into similar use, as one or two *Sedums* and *Saxifrages*, a *Santolina*, one or two *Grasses*, and sundry other plants not usually met with in fashionable flower gardens. The whole of the grounds were well managed and in good order, reflecting great credit on all concerned; for, independent of the diversity of the floral department, the botanical division was scarcely less attractive. Plants of singular growth, with some of great beauty, were given a prominent place, not, however, so as to disturb a systematic arrangement, but in such sort as to lead on the inquiring student by the most attractive means; while to the admirer of the much-abused, as well as much-vaunted flower-gardening of the present day, no place that I visited in 1863 presented greater variety.

J. ROBSON.

PACKING PHALÆNOPSIS, SOPHRONITIS, AND BURLINGTONIA.

THE peculiarities of the structure in the form of the leaves of these Orchids renders it necessary to use more care in the packing than with the majority of *Orchidaceæ*. I will, therefore, give my reasons for the different packing of the above, *Phalænopsis* more particularly, the leaves of which are of a much more tender nature, few in number, so succulent, and susceptible of injury, hence very liable to rot and fall off from one plant on to another, and cause decomposition of the whole. To prevent this I would, previous to importing, have them partially established on logs of wood from $2\frac{1}{2}$ to 3 inches in diameter, and in length to fit the inside of the case, such to be charred a little on the outside to keep down fungous. To this I attach great importance. Having

established them on logs, carefully and very tenderly wrap each leaf in tissue paper, put it but once round, as more than one thickness will have too absorbent a property for the plant. Each leaf must then be very tenderly tied to prevent its moving. The logs so prepared are then ready for placing in the case, and must be fixed clear of everything inside by means of screws through the end of the case, and entering the log. This will save much knocking about in unpacking, which must be the case if nails are used. The logs will then appear to be slung from one end to the other. A covering must next be constructed of sticks and moss clear of the plants, so as to leave them in a chamber, which will have the appearance of a moss partition. More logs can then be introduced as before, so continuing till your case is full.

As to the time of removal for Orchids for importing, the most fit period is just as the plants have completed their growth, swelled off their bulbs, become a little consolidated, and have the appearance of a partial ripening.

By whatever route the cases are forwarded, I hold that nothing surpasses the moss alluded to in my previous paper for packing the whole order of Orchidaceæ. Having received consignments from nearly all parts of the globe where Orchids are found, both by sea and overland route, in Wardian and closed cases, those packed according to my directions arrived in much better condition than in any other mode I have witnessed.—A LOVER OF ORCHIDS.

CLOTH OF GOLD AND GOLDEN CHAIN GERANIUMS.

In reply to your correspondent "J. A.'s" inquiry concerning the growth of Cloth of Gold and Golden Chain Geraniums, permit me to remark that I have had some plants of Cloth of Gold which, like his, scarcely made a start till within the last month or five weeks, and others which grew freely and looked well all the season.

The stand-still plants had been taken up from the beds last season, potted, and kept in a moderately warm place through the winter, and were rather severely pruned in March to obtain cuttings. The plants from these cuttings, as also those struck in the previous autumn, did well; and I attribute the failure of the old plants to make growth in the early part of the season to the severe cutting-in, and the forcing which they received to produce the growth for those cuttings.

Golden Chain, which had not been subjected to such severe treatment, made earlier growth; but in this case, too, the autumn-struck plants grew the most freely, although not so freely as the Cloth of Gold.

I may remark, too, that I saw last season Golden Chain in a newly-made garden grow with a vigour surpassing anything I ever saw in Cloth of Gold. In this instance the plants were young.

Madame Vaucher Geranium has been quite a rosy pink with me this season till quite lately, when the flowers have been nearly a pure white. I have heard Snowball and White Tom Thumb similarly spoken of as respects their being anything but white during the hot weather. Have any of your correspondents found them return to their professed shade since the rainy weather set in?—J. P. M.

CLOTH OF GOLD has done well here (Upper Clapton, Middlesex) this season, much finer than ever we had Golden Chain. Indeed, it has been so beautiful, that we thought it rivalled the Calceolarias, and wished we had planted more of it instead of them. We find it requires a little extra nursing. Our beds are dug deeply in the autumn, and for the more delicate Geraniums we fork in during March a plentiful supply of leaf soil, or rotted bog earth. This makes them grow much stronger.—W. C.

SOCIÉTÉ CENTRALE D'AGRICULTURE, D'HORTICULTURE, ET D'ACCLIMATATION DE NICE.—On the occasion of the "Concours Régional," which will be held at Nice in April, 1865, this Society has decided upon the organisation of a Grand Horticultural and Industrial Exhibition, which will be in-

ternational and universal. This project has met with the warmest encouragement from the Government, and will be carried out under the special patronage of their Majesties, the Emperor and Empress.

REMARKS ON SOME DIOECIOUS PLANTS.

BY W. G. SMITH, ESQ.

(Read before the Society of Amateur Botanists.)

Of late years, various hypotheses have been started, both in this country and on the Continent, which, though more or less borne out by experiment, are on the whole so thoroughly opposed to all former experience, that believers in them have been but few. I allude in particular to spontaneous generation, to the power possessed by Rotifers¹ and some other animals to survive drying, baking in ovens at a great heat, saturation in powerful acids, &c., and on the application of some restorative to become once more full of life and instinct; and to the so-called pathogenesis, or the possibility of certain female plants and animals possessing the power of fertilising their own ovules and ovums without the action of the male principle.

It is principally on the latter that I propose making a few remarks, and recording some of my own observations.

In Bryonia dioica, and probably all other dioecious plants, I think we may start with the assumption that when the ovules have been fertilised apart from contact with the pollen of the male, a fertilising influence has been at work in some form or manner. I think an exaggerated importance is attached to the functions of various organs. For instance, although anthers generally bear the pollen, under certain conditions other organs will produce pollen. Instances of this are on record. I have near me a drawing, copied by myself from nature, showing the pistil bearing an anther as well as a stigma (in *Crocus vernus*); on the end of this anther again is another small stigmatic surface. It is also well known that petals occasionally bear anthers, generally situated in their thickest part, as in *Nymphaea alba*, and in the double forms of the garden Poppy. I have frequently seen the middle of the petal of a double Poppy open and discharge pollen, showing the close affinity of all the organs of the flower. Instead, then, of jumping to the conclusion that a female flower is able to fertilise itself without pollen, it would be well, in all dioecious flowers, to see if the pistil or petals are ever capable of producing or do produce pollen; or if abortive forms of the stamens occur, that on occasion may produce pollen so as to fertilise the ovules when the flowers are absent.

In my mind it is an open question as to whether a female flower cannot be fertilised without the direct influence of true pollen. If anything will do this, I am inclined to think it is the nectar found at the base of the petal; this is probably the nearest ally to the true pollen, and in some Ranunculaceæ I have observed the nectary bearing pollen in the place of nectar. In some female flowers that bear this nectar-like secretion, is it not probable that on certain occasions the nectary may play the part of the anther of the male? Or may not pollen be at times produced from a petal on its hastening forward to the next stage of flower growth, a stamen?

It has been stated rather positively that the female flowers of Bryonia and other plants have no traces of stamens or anthers. M. Naudin of Paris, in his valuable and highly interesting paper "On the Formation of Seeds without Pollen" ("Comptes Rendus," 1856, p. 538, and republished by Dr. Seemann in "Hooker's Journal of Botany and Kew Miscellany" for 1857, ix. p. 53), has the following passage:

"In 1854, I observed in ground close to a wall and palisades, belonging to the Museum, a female plant of the common Bryony (*Bryonia dioica*), quite alone in this ground, and which, from thousands of flowers which it had produced, had set and ripened fruit in very great numbers, but in a proportion incomparably less than that of the flowers. These fruits contained well-formed seeds. In November of the same year I had fifteen of them sown in a hothouse; all came up very well. In 1855 this female Bryony fructified as it did in the preceding year, and in the same proportion as it had done in 1856. I have examined the flowers many times, and have never found in them any traces of anthers.

We may then suppose that some fruits which it produced each year proceeded from fecundations effected by the intervention of insects. What follows will prove that this reason cannot be advanced.

"In April of this year I caused to be planted, in the same border where the Bryony was found, a second female specimen, raised from seeds produced in November, 1854, and which till then had remained potted. Doubtless on account of its youth this plant did not develope much, but it was covered with flowers, which, without exaggerating, I may reckon at many thousands. All were females; in some I perceived not the slightest vestige of anthers, and yet, remarkable to say, all, or almost all, produced fruit now ripe, which gave to the withered branches of the plant the appearance of long red bunches. I took a hundred of them promiscuously, to examine their contents; of this number there was a dozen containing no seeds at all, forty-five with only one, twenty-nine two, eleven three; there were only two with four seeds, and one alone which contained five. This result does not sensibly differ from that presented by the plant which grew close to a male plant.

"Yet while this second Bryony was literally covered with fruit, the old plant, distant from it only a few yards, bore neither more nor less fruit than it did in the preceding years. We cannot say, then, that in both fecundation may have been effected by insects carrying pollen of the species, since it is evident that they would have equally taken it to both, and that both in consequence would have equally borne fruit. Now, as I have just said, the difference in this respect was enormous. I can only explain it to myself by the particular individual dispositions; in other terms, by veritable idiosyncrasies."

At the base of the petals of the female flower of *Bryonia dioica* may be seen a sort of globular gland surrounded by hairs. This would seem to answer to the anther of the male. It is very rarely if ever absent, and sometimes takes a slight twist, like the normal anthers. It is a very minute object generally. I have had some difficulties in carrying out my experiments on this plant, but may mention one that is decisive. I gathered, several times, branches of the female plant with the flowers in bud, and kept them in water under a propagating-glass till they opened. When examined, one or two grains of pollen were found in nearly every flower, probably produced by these gland-like bodies to which they were attached. The ovaries of most of the flowers became swollen, but eventually dropped off. One peculiarity of the plant is, that the opposite sexes are generally found in groups, and the two sexes very rarely together. I have once seen a male and female stem growing close together, but could not ascertain whether or not they were thrown out from the same rootstock, although I think it probable; for, judging from the natures of other plants, there is no reason to believe that the rootstock is male or female, but that it is capable of throwing up either a male or female stem at different times, as circumstances or the nature of the plant may direct. I know this to be the case in another instance.

I may, however, say, that in various berries of the Bryony I have planted in my own garden, all the seeds contained in each separate berry produced plants of one sex, for a single berry does not appear to contain seeds capable of producing plants of both sexes the first year. This sufficiently accounts for the groups of male or female plants usually seen in the hedges.* Should a bird, for instance, drop a berry in any locality, it would produce a group of males, or a group of females, although I am inclined to think a male plant one year may become a female plant another year. But in *Bryonia*, contrary to my experience in other dioecious plants, I have never found occasional male flowers on a female plant, or occasional female flowers on a male plant. It is common to find a female plant or a group of females (with no male anywhere near), with all the seeds fertilised and covered with ripe berries. In some female plants growing in my neighbourhood, and removed a considerable distance from all males, I have seen nearly every flower fertilised; and when the female flowers were examined, I found their

interiors profusely covered with pollen, evidently brought from male plants by insects, as every one who has noticed *Bryonia* must have observed what a profuse quantity of pollen their anthers shed.

I will now turn to *Lychnis diurna*, or *dioica rubra*. I am not aware that the female form of this plant is said to be able to fertilise itself, but to a superficial observer it might well be supposed to do so. From my own experiments I well know individual specimens of this plant to be sometimes entirely male, then monoeious, and eventually entirely female. I have a plant in my garden, the rootstock of which has produced all three since the early spring of this year. When first planted it threw up stems containing male flowers only. This continued for a month, when females began to appear; but it is clear, that if all the males had died off before the females were produced, no seed could be brought into existence; on the contrary, when all the males had died and dropped away, and females only were on the plant, all the ovules were fertilised without exception. How was this effected? Was parthenogenesis at work here? Not so; the original males, long since dead, caused the fertilisation. But how, if the males were dying off when the females were only in bud? By this simple contrivance of Nature:—When the female flowers had attained maturity, and were shedding their pollen, the female buds appeared below, with their stigmas hanging out of the buds, so that there was a very good chance of all the females being fertilised, although only in bud. Nor was this all, for I believe in this plant, as in nearly all others, insects are designed to play their parts. At first sight, it is not clear how insects could help this plant, but I will explain. In the first place, the crimson colour of the petals of the male flower must be attractive to insects. Suppose an insect has got the pollen from the male on to his head, legs, &c., and the crimson petals of the female have not yet appeared, what is there to attract him in turn to the female? Simply this: whilst the male has got a calyx barely marked with red lines, the calyx of the female bud is much more crimson and attractive; so that, whilst an insect is attracted by the crimson of the petals of the male, it is in turn attracted by the crimson of the calyx of the female, and if the insect alights at all he must go at once on to the stigmas, and so Nature's object is effected.

When one observes in the vegetable kingdom the various forms of plants, some dioecious, some partially so, some hermaphrodite, and others seldom or only under peculiar circumstances ripening their fruit, the question suggests itself as to whether all plants are not gradually changing from one state to another. I am borne out in this hypothesis by Mr. Darwin, who remarks that *Primula* is probably gradually becoming dioecious from the hermaphrodite condition. Or, whilst one set of organs are being suppressed, the complementary set are being more fully developed. I believe this to be probable, and supported by many facts in both the animal and vegetable kingdoms. If we take the animal kingdom, we find a limited number of creatures unquestionably hermaphrodite, but of a very low order; but if we call all the creatures possessing separate sexes dioecious, we then come at once to a much higher order of being. I believe it is the same in the vegetable kingdom, for where the sexes are separated there must be more difficulty in breeding, the act of fertilisation depending upon external, or, perhaps, accidental circumstances. The lower any object is in the scale of nature, either animal or vegetable, the more profusely it multiplies itself; whilst the higher, the greater difficulty there is in breeding. Take horses, for example. Every one knows the difficulty there is of increasing the number of highly-trained animals. Even in man, as a rule, the lowest and most debased races increase most rapidly. The higher order of animals produce one at a birth, the lower hundreds or thousands. The same applies to vegetable life; the lower the plants the more profuse the breeding, as in the Toadstool, with its millions of spores; and in the opposite degree those flowering plants are the highest that produce the least number of seeds, or that have the greatest difficulty in propagating themselves.—(*Journal of Botany*.)

* I think seeds themselves are probably not either male or female, but that after-influences produce the sex; as in animals the sex is not developed in the early embryo life of the creature, nor till the embryo has attained a certain age.

BRIGHTON SHOW.—We are glad to find that the gentlemen of the north are well maintaining their reputation for

producing first-class fruit, and especially Grapes. We have just had another instance of their success, for Mr. Henderson, of Trentham, gained at the autumn show held at Brighton on the 14th and 15th inst., the first prize for the best collection of eight dishes of fruit, and the railway cup as well. Such a position is not easily won at the Brighton Show, which is second to no provincial show in the kingdom.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE September Meeting of the Entomological Society was held on the 5th inst., F. P. Pascoe, Esq., F.L.S., President, in the chair.

The ravages of the Turnip grubs, or caterpillars of a species of Moth belonging to the genus *Agrotis*, were brought under the notice of the members by Mr. Dunning, the Secretary, who had received a number of living specimens from a correspondent in Yorkshire, who had suffered a loss of at least £150 by their attacks on fields of Turnips; and Professor Westwood gave an account of their attacks on different kinds of vegetables in his own garden near Oxford. Turnips, Beetroot, Carrots, Endive, Lettuce, Potatoes, greens of various kinds, and Sea-kale had all been attacked, and so numerous were they that not fewer than twenty-nine had been taken around the root of a single Broccoli, and his gardener had, day after day, collected a pint measure of them, which were greedily devoured by fowls. Hand-picking and laying traps (by burying cabbage leaves or stems), were, indeed, the only available remedies against their attacks.

Mr. Ianson exhibited four minute species of Staphylinidae recently taken in this country, hitherto unrecorded as British.

The Rev. Hamlet Clark exhibited a beautiful Beetle, *Buprestis ocellata*, a native of central India, which had been found alive on shipboard, about fifty miles from Madagascar, and which was supposed to have been reared in wood brought from India. Various instances were, however, quoted of the powers of flight of insects caught at long distances from land. Some have been taken 150 miles from the coast of Africa; the north-east trade winds having evidently had considerable influence in allowing the extension of their flight.

Mr. Lowne exhibited a collection of Coleoptera and Lepidoptera taken by himself in the spring of the present year in the Holy Land, and pointed out the difference of several of the species from closely allied forms found throughout Europe. Amongst these was a modification of the *Papilio Podalirius*, which was stated not to occur to the west of the river Jordan. The geographical range of plants as well as insects was indeed strongly marked in Syria, the plants to the south of the Dead Sea being quite distinct from those of more northern localities.

Mr. Larkin exhibited a newly-invented glazed case or frame for exhibiting insects suspended on the walls of rooms.

Mr. Tegetmeier called the attention of the members present to the series of letters recently published, anonymously, on the economy of the Hive Bee, in the *Times*, by Dr. Cumming, many of the statements in which were the "most incorrect that could be imagined, and full of ridiculous and disgraceful blunders." Many of these statements were reviewed and their incorrectness shown. Thus a swarm was said to consist of five or six thousand individuals, and to be of the size of a bunch of Grapes, whereas a good swarm would fill a peck measure. Bees were said to be early risers, whereas it is seldom that they are out of the hive before eight o'clock, even if the hive be exposed to the sun. Again, they were said never to interfere with the property of their neighbours, whereas the deprivation of weak hives by robber bees from strong ones, was a fact known unfortunately by every bee-master.

Professor Westwood and the Rev. Hamlet Clark expressed their regret that such a host of misstatements should have appeared in a leading journal, more especially as it appeared that they had been written as advertisements of a work since announced for publication by Dr. Cumming.

Memoirs by Mr. Hewitson containing descriptions of new species of exotic Butterflies; by Professor Westwood on new species of Sagrides and Megalopides, Plant Beetles with thickened hind legs, natives of Africa, Asia, and Australia;

and by the Rev. Hamlet Clark on a number of new species of Plant Beetles, belonging to the genus *Schematiza*, from the New World, remarkable for their striking resemblance to species of *Lycus*.

Lieut. Beavan communicated a memoir on the natural history and transformation of the Tusseh Silk Moth of India.

PEACHES IN AMERICA.

ONE of the *Tribune* reporters has been among the Peach men, and visiting all the railroad depots and steamboats bringing Peaches to this city, and Jersey city opposite; also most of the large wholesale dealers and receivers of the fruit. He has collected many statistics and items of interest and value to those living outside of the city, and who have faint conceptions of the magnitude of the trade. They would receive considerable enlightenment by visiting Jersey city about noon any day, except Sunday, and witnessing the arrival of the Delaware Peach train of twenty to thirty cars, completely filled with Peaches, each car containing about five hundred baskets, or their equivalent in crates. We will here remark that the Peach crop of Delaware and New Jersey, is larger than in any former year since 1857, much the largest portion of which is sent to this market, though large quantities are sold in Philadelphia, and smaller amounts in Baltimore and Washington.

The majority of those already sent in are from Delaware, where the yield is not only very large, but the fruit also of fine quality. About one-half the crop of that State is now in, and South Jersey is sending freely, while those from the central portion of the State are just beginning to arrive. The Jersey yield is generally good, though the drought materially lessened the crop in some localities.

The railroads passing through the Peach regions run special trains during the fruit season made up wholly of Peaches. Freight cars, and in some cases cattle cars, are fitted up with shelves for carrying four tiers of baskets, and they are pressed in so closely that there is very little motion to them. The baskets are generally uncovered, though a few have cloth covers tied on. Some extensive growers use slat crates instead of baskets, a portion of them holding two Peach-baskets, or one bushel each, with a partition through the middle to relieve the pressure, others holding a single basket of fruit. These crates are very convenient for reshipping the Peaches further north, and are gaining favour among dealers. A car can be packed full of crates without reference to shelves, the fruit can be inspected from all sides, and pilfering boys who throng about the trains upon their arrival cannot purloin the Peaches.

As already remarked, the railroad companies drop these cars along the route, where growers fill them, and at the appointed time, generally late in the afternoon or at night, they are picked up and taken to the city, intending to reach there early in the morning. There is a great deal of complaint regarding transportation this season. The crop is so large, and the railways so taxed with passengers and freight, that thousands of baskets are not unfrequently left behind to rot, or they are subsequently sent forward in a damaged condition.

Most of the Peaches are consigned to commission dealers, some of whom are interested in the orchards; but generally they merely receive and sell the fruit on commission, meeting the trains, and either selling in lots at the depot, or carting it to their stands, generally in the vicinity of Washington market. These large dealers seldom retail, but sell in quantity to up-town grocers, and to shippers, or they send direct to Boston, Providence, Hartford, or some other eastern city, to fill orders on hand. Nearly one-half of the Peaches now coming here are either sent up the Hudson, to the various cities along the river, or to the eastern cities, and more would be sent could freight or express accommodation be had. The commission for handling or selling is 10 per cent. on sales. The prices obtained for good fruit have thus far averaged about 1 dol. 25 cents. per basket, ranging from 1 dol. to 1 dol. 50 cents. Some of the dealers receive one to two thousand baskets per day, the carting and disposal of which keeps them on such a stretch, that they feel a relief when the season is over.

The proprietor of an extensive glue factory in Philadel-

phia having a large amount of waste material, so offensive that the authorities demanded its removal, bought a tract of wild land in Delaware, and kept a sloop carrying the refuse from the factory to this tract. The waste was spread over the surface quite thickly, and, after two or three years exposure, the ground was put in order, and a portion planted with Peach trees as an experiment. They succeeded so well that he kept on, until he now has 600 acres in trees. The manure will doubtless be of a lasting nature, and its strong animal odour may be offensive to the borer, that pest of the Peach-grower.

The king of Peach-growers, however, is a Jerseyman of the name of B. Reed, who, in connection with his sons, expects to market one hundred thousand baskets. His trees are in Ocean and Monmouth counties, New Jersey. One orchard contains forty-six thousand trees, and he is now sending from one to two thousand baskets to this city daily. The fruit is of good quality, and is sold wholesale at an average of about 1 dol. 12 cents. per basket. The most of his crop is still to arrive.

Some of the growers are nurserymen, and raise their own trees; others, though not nurserymen, grow their trees, but most Peach-growers buy their trees, one year old from the bud, of nurserymen. They begin to bear the second year from planting, and yield a full crop about the fifth year. It is rarely profitable to keep them more than ten years, and it is useless to plant a second crop of trees on the same soil. Large growers often buy a farm with a record clear of Peaches, plant it with this fruit, and while still in vigour buy another farm to succeed it, selling the first for ordinary farm crops.

It is said that after a rest or change of some ten years the soil will again bear Peach trees; but most growers prefer to try a new or fresh locality. In planting the trees are set about 18 feet apart, and reference is had to the kinds ripening in succession, so as to prolong the season. Quite an effort is made to originate late sorts, as they usually bring high prices after the season is looked upon as being over.—(New York Tribune.)

ORCHARD-HOUSE AT GREAT MARLOW.

AS well as many others have been watching the late controversy with regard to orchard-houses. At present it is a subject of great importance, from the fact that orchard-house culture is extending in all directions except, perhaps, in very large gardens. For some reason a great many gardeners at such places do not take kindly to this movement. This may arise from their having abundant means of accommodating most fruit trees under glass in good bodies of soil, in which way the trees do not require one-third of the attention or that extra demand upon labour that is necessary to insure success in pot culture. At the same time no gardener ought to try to write the system down by pointing out failures, most frequently the result of inattention or helplessness; for without considering the large class to whom this mode of culture affords a great amount of pleasure, a comparison between a large collection of fruit scattered over an extensive place, and an orchard-house where all good varieties can be brought together and their merits compared, would, as far as enjoyment goes, result in favour of the latter being a useful appendage to every place. But I think any one, unless stubbornly prejudiced, has only to see a successful one to be converted.

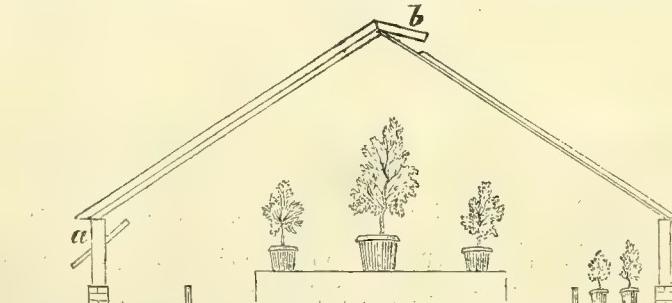

In proof of my opinion: about the beginning of the month I accidentally visited an orchard-house in company with a gentleman of high authority in fruit matters, but he believed in none of those things called "Orchard-houses;" on leaving, however, he had certainly changed his opinion, and no wonder, for that house, at least, is a great success.

It belongs to Mr. Berger, of Great Marlow, and was arranged and constructed by himself. It is 75 feet long by 30 feet wide, with a height in the centre of 13 feet. As will be seen by the section, there is a bed in the centre, raised 18 inches, with a 3½-foot path all round, leaving a five-feet border on the level on each side. Air is admitted by the front light, *a*, being hung on a pivot, and by the top, *b*, moveable all the length. The whole was designed by Mr. Berger. The fittings are exceedingly tasteful, and very different from the makeshifts we frequently meet with. At the time of our visit most of the Peaches and Nectarines were over, but there were still sufficient to show their quality. Mr. Neighbour, the very intelligent gardener, to whom a great deal of the success is due, informed us that this season there had been 144 trees in the house, consisting of Apples, Apricots, Cherries, Nectarines, Pears, and Plums. Most of

the trees are in 13 and a few in 16-inch pots. The average yield was three dozen and a half to each tree. This includes Cherries which I suppose will hardly be considered fair. Upwards of 214 dozen Cherries were gathered, of Apricots 83 dozen, of Peaches more than 38 dozen, and of Nectarines 43 dozen. These were not small or badly-coloured fruit, for some of the Grosse Mignonne Peaches weighed upwards of 8 ozs. each; Royal George and Barrington, 9 ozs.; and many of the Nectarines 5 and 6 ozs. Now, if we take the stone fruit, excluding the Cherries and Plums, at the average price of 6s. per dozen, we have nearly £50; or, as good Apricots might be had for 4s. a-dozen, and Peaches and Nectarines at 7s., if we take the average price at 5s. per doz., we have £41 for these alone. Of Plums there were 79 doz., of Pears 38 dozen, and of Apples 34 dozen.

The Plums were very fine, several varieties, such as White Magnum Bonum and Pond's Seedling, weighing 5 to a pound.

Pears were magnificent. I do not know anything more striking than a quantity of monster fruit hanging all over such diminutive-looking wood and trees. Some of the fruit, such as Colmar d'Aremberg, weighed 19 ozs., and many other sorts 1 lb. There is a great difficulty in distinguishing the variety when so much overgrown. Some of the Emperor Alexander Apples measured 14 inches in circumference and weighed 1 lb.; several others did the same, and all, be it remembered, were very small trees in pots. None of these are plunged, but placed upon the surface, allowing the roots to run through the bottom into the border. They are mulched several times in the course of the summer with good leafy loam, and liberally supplied with water during the fruiting season. I should consider this one of the great points of success. The gardener told us that watering took up more than one hour every morning all through the hot weather, and he made a point of passing through several times in the course of the day. It must be evident that if small plants with that amount of fruit to feed are allowed to become once thoroughly dry and flag, they must sustain a severe check, and if they retain the fruit after this it will never attain the same size that it would if this had not occurred. In autumn the trees are disrooted and potted in fresh-prepared soil, the whole being placed together on the bed of the house; the side borders are then filled with Lettuce, Endive, and dwarf Cauliflowers, all of which we were told do well, and are never injured by

the most severe frost except a few close to the sides. Salads are thus producing throughout the winter. Think of that all ye who have French cooks to supply.—J. F.

MONSTRUEUSE DE DOUÉ PEACH.

LIKE your correspondent, "W. M." I have a Peach under this name. It came from France two years ago. It does not agree with the description of Belle de Doué, in Dr. Hogg's "Fruit Manual." The glands are kidney-shaped, not round; the fruit inclining to oval, very downy, small, and flavour not first-rate, but that may be from over-cropping; flesh melting red next the stone, from which it does not part freely; colour dark next the sun, but not so much so as some other varieties; flowers small. Does "W. M.'s" Peach agree with this description? If so, we may console ourselves that we may have something new if not good.—W. D.

[Monstrueuse de Doué, and Belle de Doué, are distinct. The former, with which your description agrees, is not of much account. The Belle de Doué is excellent.]

GROWING MONSTER MUSHROOMS.

ON August 10th appeared in the *Times* an account of the system as practised in France of growing Mushrooms. Can you inform me if any of your correspondents have tried the system, and if so, with what results? or if you think it likely to be attended with success?—*Basford Park*.

[The communication to the *Times* is as follows:—"The following notice concerning the production of Mushrooms of gigantic size may interest many of your readers. It was communicated to the French Academy in 1861 by Dr. La Bordette (*Vide Comptes Rendus*, t. 53, 1861, pp. 235 and 671). The doctor was engaged in experimenting upon the subject during several years. The Mushrooms are first developed by putting their spores (dust-like seeds), upon a glass plate spread over with sand and water. The most vigorous individuals are selected, and it was with the mycelium (spawn), of these that he obtained the remarkable specimen presented to the Academy. The process is as follows:—

"A moist soil, composed of vegetable mould from marshy ground (known as *terre végétale de maraîcher**), placed in a cellar, is covered first with a layer, about 10 inches thick, of sand and river gravel, and then with a layer, about 6 inches thick, of the mortar of old buildings got during their demolition. This soil, after the spawn has been sown in, is sprinkled with water containing about 32 grains of nitrate of potash (saltpetre), per square metre (about 10 square feet). The action of the nitrate of potash was manifested during six years.

"Dr. La Bordette informed the Academy that he had succeeded in raising Mushrooms on a soil formed entirely of sulphate of lime (gypsum, which by calcination yields common plaster of Paris), well beaten down. For manure he substituted nitrate of potash buried along with Mushroom spawn at a depth of 3 or 4 millimetres (0·12 or 0·16 inch). Nothing else was added. 'Under these conditions,' says the doctor, 'the growth of a variety of the common Mushroom (*Agaricus campestris*), which may be termed "Giant Mushroom," takes place indefinitely. While, according to the usual and complicated method of culture, the average weight of Mushrooms in the adult state is 100 grammes (1544 grains), Mushrooms may be developed by my method weighing on the average 600 grammes (9263 grains, or somewhat more than 14 lb. avoirdupoise).'"

We shall be obliged by any of our readers stating the results of any trials they have made of this system. If none of them have tried it, we wish some of them would. Although we are not sanguine of great results, yet let no one condemn the statement until tested by experiment.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

It would be advisable to have two separate receptacles for garden rubbish attached to every kitchen garden (and we

* Not from marshy ground, but from a market-garden.—[Eds.]

allude to this matter at present, because the accumulation of weeds and decayed vegetable matter is considerable at this season of the year), one to receive the matter convertible by gradual decomposition into manure, the other to contain every substance that can be conveniently burned. A good reserve of burnt earth and wood ashes would be useful in every garden; the latter may be advantageously substituted for manure of a stronger character in rich soil which it is desirable to relieve. *Cauliflower*, prick out, about 3 inches apart, the young plants of the August sowing for next year's early crop into beds of light rich soil to be watered and shaded until they take root; also the young Cabbage plants from the sowing made at the same time. *Cucumbers*, those on ridges will now, since the rain, give a good supply of young fruit to be gathered for pickling before the fruit becomes spotted, as they decline in productiveness. *Herbs*, the decayed flower-stalks of aromatic herbs to be cut down, and the beds cleared of weeds; the roots divided if an increase is required; and the tops, if not done before, dried for keeping. *Spinach*, thin out the winter Spinach sown last month to 6 inches from plant to plant, and the late crops of Carrots and Onions. As young weeds will now begin to appear thick and fast, the hoe should be kept actively employed on all favourable occasions to keep them down, and handweed the seed-beds, for if neglected for a week or two more weeds will overrun and seriously damage the seedlings, and then increase the labour of removal tenfold.

FRUIT GARDEN.

Continue to give careful attention to the disbudding, thinning, pruning, and nailing of fruit trees as recommended in preceding weeks. *Strawberries*, plant out the strongest young runners as edgings, or in rows from 18 inches to 2 feet apart.

FLOWER GARDEN.

By regularly removing all dead flower-trusses and relieving the plants from superfluous and exhausted growths, their health and display may yet be prolonged. Borders deficient of Snowdrops, Crocus, Narcissus, and other early spring-flowering bulbs should have some introduced. Auriculas to be top-dressed, and if any are soddened with wet the drainage should be examined immediately. The young plants of Pansies obtained as cuttings or side shoots should be planted in good loamy soil well incorporated with dung. The sooner the Hyacinths and other bulbs for forcing are potted the better. The principal essential to success is having the pots filled with roots before top-growth commences; the bulbs to be selected for weight or substance in preference to size, and to be potted in half leaf mould or decomposed cowdung and half loam, with a sprinkling of silver sand. The quality of the soil is not of primary importance, as the flower-stalk will depend in a great measure upon the organised matter stored up in the bulb, and brought to perfection under the favourable influences of heat, light, and air. When potted to be placed in a frame or pit and covered with 6 inches of dry sawdust in preference to coal ashes. When the pots are filled with roots and the heads begin to sprout, they should be taken up and treated with a supply of heat, according to the time when they are wanted in bloom; but they grow stronger and bloom better when gently excited by heat and supplied with air.

GREENHOUSE AND CONSERVATORY.

The great business here will be to house the more tender sorts of plants in good condition; the pots to be rubbed clean and search to be made for worms when their casts appear on the surface of the soil. Sometimes the soil is so porous with worm holes as to necessitate repotting, which should be done at once. Any moss or weeds on the surface of the soil to be removed, and it should be fresh surfaced if necessary. In the case of large tubs or large pots, which are more unmanageable, an application or two of lime water will banish any worms that may be in them. When housed, all the air possible to be given in fine weather, even to the entire withdrawal of the lights, only reducing the ventilation when unfavourable changes in the weather take place. Each plant to be allowed sufficient space for the air to play freely around it. The Chinese Primroses to be shifted into the pots in which they are to bloom, in a soil composed of turfy loam, old cowdung, leaf-mould, and silver sand; to be planted high to prevent the damping-off in the winter, and three-

small pegs inserted close to the plant to keep it steady in the centre of the pot; all blossom-buds to be nipped off as they appear until the middle of October. The Chrysanthemums to be taken up from the open ground, to be potted in any good soil, watered, and shaded for a few days. The system of growing them in the open ground saves a great deal of trouble in watering, and after all it is rare to see them in pots well feathered with foliage to the bottom; but in the open ground they require but the small attention of stopping occasionally, and when they are potted, even if left until the flowers are expanded, they will not lose a leaf. The principal and most desirable object in the management of greenhouse plants is to procure a robust and hardy growth, and at the same time to accommodate them to the changing influence of the seasons by lessening the vital action by free ventilation and by the gradual and judicious curtailment of water. Continue to shift Cinerarias, herbaceous Calceolarias, and other such plants for early spring flowering.

PITS AND FRAMES.

Pot-off seedling Conifers into small pots; however hardy, they derive much advantage from such nursing. Establish a good stock of Verbenas in pots as duplicates of the choicer sorts; harden-off cuttings for bedding-out next season, that they may resist the gloom of the approaching winter. The smaller the pot for merely storing a plant the better.—
W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Celery.—Planted out some more beds of nice young plants where we had a plantation of Peas. Only about 6 inches of soil were taken out and as much of rotten dung added, and well incorporated with the soil for 18 inches in depth. The plants, cleaned of suckers and turned out with good balls, will be useful next spring. The older plantations have now received enough of moisture, and are growing beautifully. See previous weeks.

Cucumbers.—Turned out some young plants in a pit where we can give a little hot-water heat when desirable. The heat is supplied from a saddleback which lost the most of one side two to three years ago, and we tinkered it with a plate of iron, without using a single screw or bolt. The mode was mentioned at the time. This season we found that the water escaped, and began to fear that the other side of the boiler had gone, but on examination found it proceeded from a leakage in the air-pipes where they joined the water-pipes. When these pipes have to be taken from pipes sunk for bottom heat, a stronger material is necessary than what is wanted for gas pipes, as the earth and moisture together soon oxidise them. For Cucumbers in frames, &c., see last week.

Capsicums.—Gathered a lot, and will leave a quantity for smoking purposes. We believe that the "pastils," such favourites with some people for the destruction of insects, have a good portion of Cayenne and saltpetre in them.

Dwarf Kidney Beans.—Transplanted a lot into pots, and placed under glass in a cold pit whence they could be moved when it becomes too cold. Sowed, also, a lot in boxes, to be transplanted into pots to bear in the beginning of winter. These are obtained with but little trouble. Have some litter in readiness to throw over Beans and Scarlet Runners if we have a sudden frost. A little litter one night will often save the crop for a month later.

Mushrooms.—We believe that the rains and the cool nights are bringing these plentifully in the open pastures. We like the cultivated ones best, as there is more certainty as to their wholesomeness. Our beds in the open sheds are white all over. Placed material for some shallow beds in the Mushroom-house. The material was half-rotten dung and fresh droppings, with a little litter, in equal proportions, and half a portion of chopped dry turf, and dry parings and sweepings from roads and walks, which, altogether, we feel confident will give us good crops. Examined bricks of spawn heating in a heap, which had been more exposed to the rains than we liked. Routine much as in previous weeks.

FRUIT GARDEN.

Took the opportunity of dry days to gather lots of Apples, as the previous dryness and the winds and rains were causing

many of them to fall. Placed the fallen ones by themselves for present use. Looked over some of those previously gathered, and removed all the least spotted for present use. Apples will be cheap this season, which will be a boon to the working man. The Kerry Pippin is now in fine condition, and the earlier Ribstons. Some fine specimens of the latter from small pots in the orchard-house were very firm, crisp, and high flavoured. Such was the verdict of those supposed to be good judges. We were a little in doubt about it ourselves. Williams's Bon Chrétien Pear has also been in good condition for three weeks, and will continue a fortnight longer. The gatherings from one tree, however, took place at seven or eight times. When gathered all at once it soon decays at the heart. Few Pears are more beautiful when taken in time. Early Pears and Apples are never better placed than on clean shelves. Late ones keep well in pots, jars, and barrels scarcely covered, but without anything among them. Filberts and Nuts are now mostly ripe. Those for present use may be laid on a shelf; those to be kept a little longer, in open narrow baskets pressed firm, but so that a little air can pass through them. To have them with the outer coverings pretty fresh in spring, we know of no better plan than drying them well in a sunny day, and then packing them lightly when thus dry in jars or large garden-pots, with the holes at the bottom well filled up, covering at the top with clean paper, and then placing a thick sod grass side downwards over the paper, and keeping the vessels in a place neither damp nor dry, but rather inclined to the former. We took the hint from the squirrels. We have turned out some of their stores in April, and found even the elegant outside covering as fresh as in the month of October. If these outside coverings become dried up, black, or unsightly, rendering it necessary for the hard nuts to be removed, the latter will keep best in small vessels with just the slightest sprinkling of fine salt among them.

PLANTING.—Preparations should be made for doing this in the case of fruit trees next month, by trenching the ground, or station-planting. Everything will succeed better if the fresh roots are working freely before winter. If before the heat gets out of the ground the surface is covered with long litter, the roots will be growing strongly all the winter, and the plants will need little of the water that spring-planted trees might require. As soon as the heat in the air in spring exceeds the heat of the soil, the mulching should be all removed, so that the sun may play freely on the surface of the ground. If that is apt to dry it too much the surface soil may be stirred a little, which will keep moisture in and extra heat out. The firmer the soil the more will the ground be infuenced by heat and cold, and the looser the soil the less will it be affected either way.

Potato-pits.—We recollect a case in point which perplexed us a little in our boyish days. We helped to earth-up two pits of Potatoes. The Potatoes were covered with a layer of straw, and then by about 6 inches of soil, well trodden and beaten about the straw in both cases. Then in each case we put on 6 inches more earth, with a turf on the top of the circular cone. There was this difference, however, in one pit the outside was beaten as neatly and firmly as possible with a clean spade, and we were rather proud of our workmanship. In the other case the earth was piled on very regularly, beginning at the base of the cone, but no attempt was made to smooth it or make the outside firm. A severe frost set in, and the Potatoes in the firm and smoothed outside pit were injured, whilst those with the rough and more open outside escaped. A third party, whose pit was also smoothed outside, began to be alarmed, and scoured the ditches and sides of the road for old grass and tree leaves, which he threw on to a thickness of 2 or 3 inches, and thus made all safe. This is just one of those cases in which the tidiest way of finishing a job may not be the best. In gardening an open surface may be valuable in summer and winter.

ORCHARD-HOUSE.

The greater portion of the trees, with the exception of late Peaches and Plums, having now finished bearing, we went over the most of those in pots, beginning with the Cherries, and lifted up all the pots which were plunged two-thirds of their depth, cut off all roots that were beyond the pots, and then set them back again, and gave them a good watering, so that they might feel it as little as possible.

This will arrest mere growth, and hasten the maturation of the buds and the falling of the leaves. It seemed chiefly wanted with a few Cherry plants, and if not done, we believe that some of the buds would ere long have burst into bloom or into a young shoot instead. One plant was missed last season by mistake, and was not moved until February, but it yielded no crop in comparison with the others, though it showed freely enough, but a great many flowers dropped at the setting. There was hardly time for the plant making up for losing these roots, and it would have been too vigorous and rampant for us without the operation being performed. There is, therefore, this advantage in having fruit trees in pots, that you can make short work of the root-pruning.

We generally, when fresh arranging every spring, place some rich compost at the bottom of each hole in which the pots are placed, as we think the roots that go outside tend to swell the fruit better when they have such material to work in. The breaking or cutting off these just now hastens and helps full maturation, and the roots are forced, so long as the green leaves remain, to work more energetically within the pot. The quantities of Cherries and Plums that may thus be produced is immense, and fine Peaches and Nectarines may also be obtained *if the fruit is sufficiently thinned*. The great drawback to such pot trees is the question of water, where that is scarce. We were forced to mulch the most of ours with old hay and stable litter, which gave a rather littery appearance to the trees, though it did us service as to keeping them in fair health with but a small modicum of water.

Top-dressing and Potting.—A number of our plants are in 8 and 6-sized pots, but many of the young plants are in 12's and 16's. The latter we will try and repot before the leaves wither much. Those in the larger pots we shall, as soon as possible, top-dress, by removing as much of the surface soil as we conveniently can with the fingers and a pointed stick, and filling up firmly again with rich fresh compost. Large Cherry trees may be grown in 4 and 6-sized pots, and may remain several years in the same pots if duly top-dressed and supplied with something stronger than pure water. When pots are much larger they are difficult to move about. A time may come after a number of years when the roots may become too stunted and too crowded; but in that case we would not hesitate to repot in similar sized pots, but in fresh soil, after shaking away, pricking away, or washing away all the old earth, root-pruning when necessary, doing this after the fruit was gathered and whilst the leaves were pretty green, and syringing or shading for a few days until the roots were taking fast hold. Such a tree we would expect to bear well the following year.

Plants in good-sized pots will, however, be fertile and vigorous enough for a number of years, with the aid of the fresh top-dressing and a little stuff at the bottom of the pots. We may mention, however, that some of our best trees had scarcely emitted a root from the bottom of the pots; and but for the saving in watering, and saving the pots from a bright sun, such a pot might have done as well standing on a stone or plank as partly plunged in the earth.

Figs and Sewage Water.—Some pots of the Singleton and other kinds in the orchard-house that were not ripening kindly, we removed to a pit where they could have a closer and a warmer atmosphere. From plants in pots of White Marseilles, we had some very fine rich fruit, but some fell before reaching maturity, and the leaves acquired a brown appearance prematurely, which we attribute to giving them sewage water rather strong, and not being able to dilute or to follow with clean water. The sewage water contained a good deal of soap, and no doubt several alkalies, and our impression after watching the matter somewhat narrowly is, that Figs do not relish such nutrient, though they will find no fault with liquor moderately strong that flows from a farmyard or a dungheap. We were forced to give all these orchard-house pot plants more sewage than we liked, but we do not think any other things showed anything like dislike except the Figs. Even the Singleton has the little fruit browner than they ought to be. We like to see them light-coloured, cracking, and the rich juice standing like honey-drops. Would any correspondent give his experience of house-sewage water as applied to Figs? With us for two months it was pretty well sewage or nothing. Our impres-

sion is, that we should not like to use it so much in future for this class of plants.

Figs in the Fig-house, planted out, had the sewage more rarely, and have nothing of the brownish tinge on the leaves, though producing a heavy second crop, but which is coming lighter in colour than that of May and June. We shall thin the leaves and shoots to give more light during this and the next month, and then we will remove what fruit there is left, rest the house by exposure, in order that the leaves may drop, and then clean and fill with bedding plants for the winter, as after the end of October we do not consider a Fig worth eating.

ROOT-PRUNING OUT OF DOORS.

This is best done with any luxuriant tree immediately after the fruit has been gathered. The sooner it is done the more powerfully will it act in hastening the maturation of the buds, and thus producing fertility. The cutting of a tap root, and a few of the stronger roots, will often do wonders. It is best not to overdo at once. The operation is better performed in September than October. If the leaf is withered before the operation is performed, it is of little consequence when it is done until the buds swell, as it will tell little on the fruitfulness of the following year. If done early, and some fresh soil is packed firmly against the roots, and these roots begin to work kindly before winter, not only will the fruitfulness of the following year be promoted, but there will be vigour and energy enough to ripen the produce.

This will be the case with trees of moderate age, but when over-luxuriance takes the place of over-productiveness in trees ranging from twenty to forty years of age, the results of root-pruning, as we have proved, are less certain. Either if not enough done there is little improvement, or if too much done the trees continue too long in a languid state. In many such cases planting new trees in fresh soil, or changing the kind of the tree is the best remedy. In some cases raising the tree altogether, cutting the tap roots, saving all the horizontal ones, and fresh planting carefully, have done wonders with old trees that had become barren from over-luxuriance, or too deep planting, or from the gradual rising of the soil above the roots in old gardens.

Melons and vineeries, &c., much the same as in previous weeks.

ORNAMENTAL DEPARTMENT.

Moving and Planting Evergreens.—The change of the weather gives a first-rate opportunity for moving evergreens and other shrubs by the beginning of the next month or the end of the present. Any of these that require the reduction or pruning-in of the head should be operated on without delay, as the juices will be more concentrated in the stems and roots, and will cause roots to be sooner produced. Shrubs root-pruned last season or in the beginning of spring will be easily moved now, as the ball will be matted with roots. Without that preparation the roots should be traced as far as possible whether a ball be obtained or not, and these roots should be kept moist and shaded, instead of being dried by the sun. When packed in their new position and secured, the roots should be moderately moistened, and the soil well firmed about them. This we consider of much more importance than inundating them with water; placing them, as it were, in a quagmire sufficient of itself to destroy all roots except those of marsh or ditch plants. The water will be most wanted over the foliage in a very sunny day, and perhaps one good watering with warmish water may be needed in spring. The roots will be much better from the time of planting all through the winter if the soil about them is just moderately moist instead of being at all swampy wet. A little litter over the ground, when the weather becomes cold, to keep in the heat will do more good than inundating with water. When much planting is done the littering may be out of the question; but after moistening the roots, and firming the soil well about them, we may leave the surface rough and open and as dry as we can. All that root kindly before arrested by cold will feel but comparatively little from the increasing heat of the sun next season. All things considered, October should be the great planting month of the year.

Lawns.—These are now beautifully green, changed as if by a miracle from a rusty brown. Rolled them well and machined them—almost the first time since the drought set in; and their carpet softness and refreshing green make

some amends for the flower-beds that are waning in their brilliancy.

Flower-beds.—Most of our Calceolaria-beds were tolerable until the heavy thunder showers of last week; but the ground being too dry to keep the energies of the plants active, the flowers were washed off by bushels. Even some splendid beds of Geraniums had many black umbels that were masses of colour the day before. These picked off and the verges dressed have left them rather gay still; but the beauty of the whole picture is so broken up by the green corymbs of Calceolarias without any flowers on them, that we are going on vigorously to complete our store of cuttings of Geraniums, Verbenas, &c. Most of what we take off now we place in small 60-sized pots, putting the cuttings thickly round the outside of the pot and none in the centre, and placing them in old Cucumber-frames for the present, where they will have a little bottom heat from removing the soil and stirring up the dung, with the addition of a little litter, and covering with ashes. Damp we will guard against by air-giving, especially at night. Some Stella Geraniums thus inserted in small 60-pots, some ten in a pot, are now in fuller bloom than those struck earlier. Verbenas thus managed will be far more certain than if old plants are kept. We are giving all the air possible to the Verbenas first struck.

Raised Beds.—Here we have noticed some anomalies worth mentioning. A correspondent spoke of beds level and sunk beneath the level, as securing the benefit of all the moisture given artificially, or even naturally. Nothing feels dryness more than Calceolarias, and we believe the best we now have is a ring round one of our pyramidal beds. No, we have made a mistake, the best is planted on the flat, on a raised bed some 2 feet above the lawn, the sides covered all round with Ivy. The sides are formed of rough wood rather open, and the Ivy covers all densely, and that may have had some influence in keeping the roots cool. We ought also to mention, that the Calceolarias were rather small when turned out, but were from cuttings made in the end of October. Some beds on the flat have now scarcely a flower, and those showing will come too late to do much.

In showery days opportunity has been taken to proceed with potting, washing pots, pointing stakes, making tallies, cleaning sheds up, and to spread out long litter that a little rain may fall upon it in order to cause it to heat when thrown together. The season has as yet given us a fair portion of heat. If not, we could not have helped ourselves by heat from fermenting substances, as we had no short grass to mix with the litter, and the dry litter that came from the stable we could do nothing with in the way of watering. We have turned and turned it, getting out every bit of dropping, and set aside a lot of the best for protecting purposes in winter. Our valuable rubbish heap looks small for next season from the same causes.—R. F.

TRADE CATALOGUES RECEIVED.

W. Wood & Son, Woodlands, Maresfield, near Uckfield, Sussex.—*Descriptive Catalogue of Roses.*

Fontaine et Duvalot, 2, Quai de la Mégisserie, Paris.—*Catalogue of Bulbs, Strawberries, and Flower Seeds.*

COVENT GARDEN MARKET.—SEPTEMBER 24.

Both of fruit and vegetables the supplies are heavy. In Peaches and Nectarines there is a falling off, and Pines are just sufficient for the demand; but Grapes and Melons are very plentiful. The best two ripe Pears at present in the market are Marie Louise and Louise Bonne of Jersey. Apples are very abundant and in great variety; the best Ribston Pippins are those from Jersey. Of Lemons several parcels have lately arrived, and there has been a considerable fall in price. Large quantities of Potatoes continue to arrive both coastwise and by rail, but the demand is dull.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

SEEDLING VERBENAS (F. A. S.).—Your collection of seedling Verbenas contains some very pleasing varieties; the colours are good, but not new, and the flowers deficient in form. General Simpson and Nemesis are the types of a good formed flower; Purple Queen, Model, Medina, Aurora, Princess Dagmar, were perhaps the best. We would advise your sending specimens properly put up in a stand for the opinion of the *Floral Committee* at its next meeting.

PRESERVING WALNUTS (E. P.).—They can be kept quite moist, and peel easily, if put into a pan and placed in a cold damp cellar.

LILIUM LANCFOLIUM IN A WINDOW (M. P.).—We presume it has flowered and the foliage is now decaying; if so, repot it now in a compost of turfy loam with a little leaf mould and well-rotted manure mixed with it, providing efficient drainage. Gradually withhold water after flowering until the foliage decays, when the stems should be cut down to the surface, and no water given except a little occasionally to prevent the soil becoming injuriously dry. You may stand the pot in a cool dark place until the foliage appears, when it will require to have light. It must be kept in the pot during the winter.

TRICHOMANES RADICANS CULTURE (C. R. H.).—Drain the pot to one-third its depth, and then fill up with chopped fresh sphagnum and pieces of brown peat in equal parts. On this place the plant, laying out the creeping rhizomes or stems on the surface, which should be pressed firm. Place pieces of sandstone on and between the rhizomes, not so as to cover them, but in part to maintain the plant in a proper position and for the roots to cling to. Sprinkle with water through a fine syringe night and morning in summer; but in the morning only in winter. Cover with a bell-glass fitting within the rim of the pot, tilting it on one side about half an inch at night, but keeping close by day; place the pot in a pan of water always kept full, and keep in a rather shaded part of a cool greenhouse.

PROPAGATING DOUBLE PETUNIAS (James Hurst).—1. We strike a number of cuttings in autumn, and obtain a stock from these in the spring for late blooming. Autumn cuttings bloom much earlier and are the finest in the months of June and July, whilst spring cuttings are superior for blooming in August and September. 2. Young plants bloom better, though not more profusely, than old plants; the flowers are larger and the foliage finer.

ROSES IN POTS (A Lady Subscriber).—You may have a fine bloom at Christmas. We do not think you will gain but lose by repotting the shrubs now; but as the earth is low and sodden, turn them carefully out of the pots, remove the drainage, and replace it by fresh, placing a layer of moss over it, and then the least portion of fresh compost so as to raise the surface of the ball to within half an inch of the pot rim. Keep in a light airy situation in the greenhouse, sprinkling with water twice daily through a syringe in bright, but in the morning only in dull weather and keep well supplied with water at the root. After blooming gradually withhold water, still keeping the soil healthfully moist until April, then place under a wall or in some sheltered situation, plunging them in coal ashes in May in an open situation. Kept in June, and prune in July, and by this treatment you will have Roses through the autumn months up to Christmas.

CROCUSES AND SNOWDROPS TO BLOOM AT CHRISTMAS (J. E. W.).—If you have clumps of these in the garden, take up the most promising and pot them in six-inch pots, in a compost of loam and a little leaf mould. Water, place in a cold frame, and keep there until the beginning of November; then place them in a cool greenhouse on shelves near the glass, and where they can have air daily. Keep well supplied with water, and in three weeks place on a shelf in a house with a temperature of 50° by night, with air daily, and in another fortnight if they be not sufficiently advanced for blooming at the desired time, increase the temperature to 55°. Air, light, and not too high a temperature are the essentials to success. See what is said about them in another page.

CURE OF A HIDEBOUNDF PEAR TREE.—You advised me this spring with respect to a Louise Bonne de Jersey Pear that was hidebound, either to throw it away, which you seemed to recommend as the best course to pursue, or to keep it moist at the junction of the stock and graft with moss. I preferred trying the latter plan, as I have plenty of time on hand, and immediately set to work; and in addition to the moss heaped it well up with hosedung, and occasionally watered it, so that it has been kept quite damp all summer. The effect has been almost magical, for the blistered places are fast disappearing; and although the blossom at the time I wrote for your advice had a very weakly look, the tree has borne an excellent crop of fine fruit, quite as large or larger than the largest of Jargonelles, so that I really have just cause to thank you heartily for your advice. The tree is a bush on the quince.—A. Q.

REMOVING DWARF PEAR TREES (Working Amateur).—You may transplant them now. Disturb the roots as little as possible; move them with a good ball of earth; wash-in earth about the roots in their new locations; and stake them very securely to prevent their being wind-waved.

ALBERT EDWARD SEEDLING DAHLIA (B. W. K.).—Your seedling Dahlia is inclined to be coarse, the petals confused, and the colour dull. It may do well for the border, but requires delicacy, form, and colour to render it serviceable as an exhibition flower.

PRESERVING WALNUTS (A. G. L.).—The nuts becoming mouldy is of no consequence. Take them out of the green outer coat; wash them thoroughly; drain them, and put them into earthenware jars, and store as recommended to our other correspondent.

EYES AND NO EYES (Many Correspondents).—We have received so many letters upon this subject that we must decline inserting any more. It is enough that the hint has been given that employers "with an eye" like eyeshores removed as soon as they occur; and those gardeners who have not pursued such a prompt course will do well to take the hint. We know of no first-rate gardeners who required the suggestion.

FRUIT TREES FOR LOW WALL (An Inquirer).—Your wall is very low—4 to 5 feet is too much so for trees to be trained permanently against them. On the north aspect Morello Cherries would do well; they are of weak growth, and may be trained laterally. On the east you might put Pears and Plums, selecting the less vigorous growers, such as Winter Nellis for the former, and Green Gage for the latter. On the south you might have Peaches.

FRENCH BERGAMOT PEAR, &c. (C. J. M.).—It is impossible to say what variety you have under this name. There is no variety so named specially, and many have a French name attached. It certainly ought to succeed as a dwarf tree without a south wall. Gypsum is a good application to soil containing an excess of iron. Oak and Beech, we should think, would grow on your clayey land, but you do not say where it is situated. What would succeed inland will often fail on the coast.

MELONS SHRIVELLING (S. E.).—We are at a loss to tell what is meant by a Melon changing colour. Melons in houses require rather more moisture than those in hotbed frames. When the fruit begins to ripen, which it will not take more than a week or ten days to complete, the atmosphere should be kept rather drier, but not so dry as to affect the foliage. We think your plants have been too dry both at the roots and top, and that the fruit not fully swelled has shrivelled for want of moisture. After the fruit is fully swelled and netted completely over no amount of dryness will cause shrivelling, and it will ripen if detached from the plant and placed in a suitable temperature. The soil in which the plants are grown should be kept moist at all times; but not so much so when the fruit is ripening as when it is swelling. The flavour is likewise improved by the atmosphere being kept drier during the ripening.

CALADIUM IN A GREENHOUSE (Ruby).—All the variegated-leaved kinds require a stove temperature, and cannot be grown well in a warm greenhouse, much less in one where fire is only employed to exclude frost.

VINES FOR A COOL VINYERY (Idem).—You could not have a worse than Barbarossa, and we recommend you to plant Buckland Sweetwater instead. Esperione will do, and Muscat Hamburg is also good if a little heat be given; if not, Black Hamburg as a Black Grape, or White Frontignan as a White one, would be better. Black Prince will answer. Your inside border should be 3 feet deep—9 inches of brickbats and other rubble, and 2 feet 3 inches of compost. You may cover the border after the first three years with an inch of short manure every season, in February. The refractory Fuchsias we would not throw away, but take cuttings of it, and grow these on. Our correspondent says, "He has been in the habit of filling beds which may be vacant late in summer, with tops of Scarlet Geraniums in bloom, bordering them with Nasturtium shoots, watered once and then left to themselves." He adds, "They make a great show in autumn." We are obliged to you for the seeds.

LAUREL CUTTINGS (A Constant Reader).—They will mostly root if you take off the present year's shoots with a little of the old wood at the base, or a short heel, and insert them three-quarters of their length in ordinary garden soil, trimming the leaves off to that extent. They will nearly all root. The best time for this is the beginning of October, and they may then be put in close together, but not so as to touch each other. Portugal Laurels may be treated in the same way with a likelihood of success.

SEEDLING PELARGONIUMS WINTERING—DESTROYING WORMS (G. I. Q.).—The Pelargoniums will not do in the frame after this month, quite as much on account of cold as damp. In the absence of a better place you may possibly keep them over the winter in a window with northern aspect, only do not water much, and prevent frost reaching them. Annuals for spring blooming should be sown rather thicker, and it is not necessary to thin them unless they are very close together. Lime water made by pouring thirty gallons of soft water on 12 lbs. of lime, well stirred, and allowed to stand for forty-eight hours, will leave a clear liquid which may be applied to Calceolaria seedlings if you wish to expel worms; but are you sure that the mischief is not done by slugs, as you speak of their being eaten up? Examine the plants a short time after dark, with a lantern, and you will, perhaps, find the enemy at work.

MUSCAT OF ALEXANDRIA NOT RIPENING — ACHIMENES NOT FLOWERING (Halifax).—If the Barbarossa Grape ripens well, we think that the Muscat should be doing so likewise. Give the Muscat less air, more heat, and less water than the other varieties if the fruit is still so green. Being so healthy, we have no fear of its not ripening. We think the reason that your healthy Achimenes and Gloxinias did not bloom might be too much shade and too little heat, and that the rusty appearance is owing to the shade and dryness.

BOOKS (Jane).—We shall very shortly publish a work on Vine culture—it is now printing. Mr. Abbey's papers on Melon culture, recently published in this journal, give all needful directions. In the "Garden Manual," which you can have free by post from our office for twenty postage stamps, you will find directions not only for Rose culture, but Melon culture.

HEATING A SMALL GREENHOUSE (Calavia).—For a house 16 by 9 feet we have no doubt that an Arnott's brick stove would be quite sufficient. To insure a propagating place in spring, it would be easy to have small bent pipes, say 10 inches in diameter, placed over or in the fireplace, with their ends communicating with a small wooden tank, covered with slate or plate iron. We do not think, however, we could give details more simple as to the building of them than we have frequently done. Since your tradesman sees so much difficulty, perhaps it would be as well to have a flue as you propose, passing along one end and front, and returning to the place from whence it started. It is of little importance whether the chimney is at D, above the furnace, or at E, a little distance from it. With a high chimney the flue may be on a level throughout. If the chimney is not high, 2 or 3 inches of a rise from near the furnace, after it takes the level in the house, on to the chimney, will cause it to draw better. As you want to use it also for propagating, we think that a common nine-inch flue will suit you best. If you wish to be economical, instead of having a space between the flues, one central wall would do for both flues—that is, three side walls instead of four. At the three turns it would be advisable to have soot doors, and then, when cleaning, you would not need to disturb the flue, and the brush could be run along it all the oftener. What you style your flue and return flue would thus present a surface of 18 inches when placed together. Above that you could have a latticed or other shelf for plants in summer; and that removed, you could use the whole of the top of the flue, and especially the end next the furnace, for a propagating-box or pit in the spring. The best way to do this would be to have small shallow boxes of the necessary width made of zinc, and so that a hand-light would go over them; or you could have wooden boxes, say 17 inches wide, bottomed with zinc, and 5 inches deep in front, and 8 behind, with a moveable glass lid, and in these you could regulate the heat to a nicety, move away when more coolness was required, and bring others when more heat was necessary for them. Even with the end of the flue next the furnace much might be done with a few of these little boxes, say 20 inches long, and the cuttings could be inserted in suitable soil in the boxes, or in small pots, to be filled and put in, and taken out when necessary. Such boxes would answer well for hardening off many things when they required no bottom heat from the flue. You would see lately how have a hot tank from such a flue. The above would be simplest.

PROPAGATING PLANTS (A Young Beginner).—For twenty penny postage stamps you can have, free by post from our office, "The Garden Manual." It contains full directions for what you ask, and much more, which you, as a beginner, will be glad to learn.

FLOWER-BED PLANTING (Stella).—We would alter your circle bed and plant thus, beginning at the grass—1. Variegated Alyssum; 2, Lobelia speciosa; 3, Cloth of Gold; 4, Bijou; 5, Christine; and 6, Boule de Feu, instead of Trentham Rose. We think the Cloth of Gold will be more telling against the Lobelia than Bijou. If your plants of Bijou were strong, and the plants of Christine small, we would also change them, and this would range your variegated foliage better over the bed. If Christine is strong, plant as you propose. Trentham Rose will too much overtop Christine, and, therefore, Boule de Feu, or moderate-sized plants of Stella, would be better. To make a nice circle of all these six colours your bed for single rows would require to be 11 feet in diameter, or 10 feet at the very least—say 11 feet; then proceed thus:—Fix on the centre and draw a circle, with a line a foot in length, which will give a diameter of 2 feet. Plant that round with Boule de Feu, 9 inches apart, and then fill up the centre. This will give you a circle of fully $2\frac{1}{2}$ feet in diameter, as the plants grow, of scarlet. Then make another circle a foot farther down, and plant with Christine 8 or 9 inches apart. Then a third for Bijou, and plant about 7 inches apart. Then 10 inches farther down, another circle for Cloth of Gold, 7 inches apart; a fifth circle, 9 inches farther down, for Lobelia, and plant them 4 inches apart; and a sixth circle, 8 inches farther down, and plant with Arabis 3 inches apart. For double rows allow double room.

VENTILATION (Julia).—It is very advisable to have ventilation at the highest point of the roof of the conservatory. However, we have known plants do very well when there was little or no air given there if shade was afforded: otherwise the dry heat will be apt to call into existence shoals of red spider.

DESTROYING RED SPIDER AND THRIPS (Idem).—The means to be used will much depend on the kind of plants to be operated upon. Repeated smokings with tobacco will destroy the thrips, and repeated lashings with water and sulphur fumes (not from burning the sulphur) will keep down the red spider. For particular plants, perhaps nothing is better than dipping the plants all over into a tub of size water, just sufficiently strong to be slightly sticky when placed between the fingers; setting the plants in a shady place for a couple of days, and then drawing the fingers through them. Afterwards dip the heads repeatedly in soft water at about 90°, and lay the plants down on a cloth or a mat, and syringe them well all over. Both insects, when they get ahead, are difficult to master.

DISEASED VINE-SHOOTS (Pampinus).—We discovered no red spiders, but where they had been, and on both specimens we found about half a dozen small white thrips looking as if they had not been hatched long. Thrips and red spider are, therefore, no doubt your principal enemies, encouraged no doubt by dryness at the root of the Vines, and a dry bright sunny atmosphere. See answers to other correspondents. Watering at the roots if the border is dry, a moister atmosphere, and smoking where the Grapes are not too ripe, will be the quickest way of extirpating the thrips, and washing every open part of the wall with sulphur and soft soap, and coating the hot-water pipes or flue with sulphur, if not above 170°, will be the best thing for vanquishing the red spider, unless you can also wash the leaves of the Vines.

VENTILATING (Ignoramus).—We perceive nothing unsuitable in the mode of ventilating; but unless we knew more, we do not see the propriety of using Vines in pots in a house well filled with Vines, except for obtaining them a little earlier. We do not object to the Vines in pots being grown on a platform close to the front glass. Unless in extreme cases you will not need to whitewash the front glass, as the leaves will in general so overlap the front as to give shade enough. In the narrow upright houses at Trentham, the fruit was as near the front glass as yours will be, but no drawback was experienced on that account. The Vines in pots will do better if the pots are plunged. Muscat Grapes are dearer than other Grapes because they require more heat and more time to ripen them thoroughly.

INSECT-INFECTED VINE (W. M.).—We found no insect on the Vine leaf, but plenty of proof that it had been nibbled all over by the thrrips. If the Vines are nearly ripe, or fully so, your best plan would be to take off all the worst leaves carefully and burn them, and then sponge the others carefully with soap and water. At an earlier stage you might have smoked with tobacco; but if ripe the smoking is apt to taint the fruit. For the Muscat's shanking you can have no remedy now. Generally it proceeds from over-cropping, or deficient root-action; perhaps from the roots being deep in a cold, rich, wet border.

BONE DUST FOR VINE-BORDER (Pond-dhu).—Spread the bone dust on the surface of the border, and fork it in, not disturbing the soil more than 9 inches.

CUTTING FURZE HEDGE (E. S.).—Whether you mean clipping or cutting down a furze hedge, the best time for the operation is in dry weather, at the end of February or early in March.

NAMES OF INSECTS (A Farmer's Wife).—The little beetle you have sent, as found in your bed-rooms, chairs, &c., is the *Ptinus hololeucus*, now spread over a great part of England, but which we believe was imported into England from Russia about thirty years ago in a cargo of leather or skins. We do not think they breed in the Ivy; possibly their larvae feed upon refuse animal matters about the house. Their occasional appearance in great quantities in houses is, however, a mystery. The larvae of the *Ptinus* generally feed on dry animal matter, whilst the *Anobiums* (an allied group) feed on old wood. You would confer a benefit by hunting out the place of feeding of this species in its larva state.—W.

NAMES OF FRUIT (J. N. P. S.).—1, Achan; 2, Williams's Bon Chrétien; 3, Louise Bonne de Jersey; 4, Beurré Diel; 5, Beurré Duhaume; 6, Marie Lonise; 7, King Edward's; 8, Comte de Lamy; 9, Marie Lonise; 11, Ne Plus Meuris; 13, Beurré de Rance; 14, Conseiller de la Cour; 15, Grosse Calebasse. It is quite impossible for us to repack fruit sent to be named, and return it. (*T. P. H. B.*).—How can you have the conscience to ask us to name twenty fruits, and such a lot of bad specimens as they are? We have named all that are worth naming. 1, London Pippin; 2, Nonpareil; 3, Lemon Pippin; 4, Northers Greening; 8, Scarlet Nonpareil; 9, Winter Greening; 13, Royal Russet; 14, Yorkshire Greening; 16, Beurré de Rance; 17, Glou Moreau; 19, Passe Colmar; 20, Beurré Rose.

NAMES OF PLANTS (Sutton).—It is *Cotyledon umbilicus*, a common plant, not at all confined to Guernsey. (*Georgey*).—1, *Datura stramonium*; 2, *Buddleia Lindleyana*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

METROPOLITAN POULTRY SHOW.

I AM glad to see that one of your correspondents has broached the subject of a London poultry show. I feel certain that it would be successful if properly timed and managed.

The great success of the Birmingham Show has no doubt arisen from the fact that it is held simultaneously with the cattle show; and there can be no reason why a show held at a convenient place in close proximity to the Agricultural Hall at the same time as the Smithfield Cattle Show should not be a great success. The only thing wanted is a suitable building suitably placed, and there alone is the difficulty; but I fear it is an insuperable one.—P.

UTTOXETER EXHIBITION OF POULTRY.

THE Staffordshire Agricultural Society was first established in the year 1844, and, consequently, it has now stood the test of twenty years. For a considerable number of years past poultry has held an important position at its annual meetings; and if anything were necessary to prove how popular this portion of the display is, we can confidently refer to the absolutely thronged state of the very large tent in which the poultry was exhibited, and that from the very time of opening to the public, to its close. It must not, however, be for a single moment supposed that this remarkable influx of visitors gathered themselves within the tent devoted to poultry from any stress of weather: nothing of the kind, for, on the contrary, a more lovely, genial autumnal day could scarcely be imagined, and yet throughout the whole time the fair sex were carefully inspecting by far the best collection this Society has ever called together. We may truly say, that scarcely the most fastidious amateur could find a really bad pen among the whole, and we were pleased to hear that the entries were more numerous than ever. The situation of the show-field was a most suitable one, and the scenery was very extensive; whilst to render the day's pleasure even still more enjoyable, by the kind and ready permission of A. H. Vernon, Esq., the excellent band of the Second Derbyshire Volunteers enlivened the proceedings, thus adding very much to the gaiety of the scene.

We must now take a brief review of the various classes in the order they appear in the printed catalogue. Black-breasted and Brown Red *Game* fowls head the list. It was a matter of general remark, that not a single first-rate pen

of the latter colour was to be found, whilst the Black Reds were better than at previous meetings. The pullets in the first-prize pen were remarkably well-developed specimens, but the cockerel, to our ideas, appeared as though it had been over-run on its "walk" by an adult male bird. The second-prize pen were a remarkably Game-like-looking trio, but were evidently, though so well bred, wanting in strength and bone, had they been tested in the cock-pit. In the next class for Game of any other colours, a pen of Duck-wings stood first, but the cock was undoubtedly too light-coloured in the shoulders, and more leggy than desirable. This was one of the weakest classes in the Show, the entries consisting of only three pens. We now proceed to the Spanish, which were such as would add credit to any show. It is difficult to call to mind a better competition than ensued between the successful pens. The faces of the first-prize birds, though but little, if any, above half the age of their competitors, reminded us strongly of the pens of Spanish shown some years back by Mr. Peck, of Wigan. They were of extraordinarily fine quality, and as delicate in appearance as white kid. They were the property of Mr. Lamb, of Wolverhampton. Mr. Rodbard's second-prize pen were remarkably well-grown specimens, but the cockerel when two years old will be too much corrugated about the face for a first-class specimen. We now come to the Dorkings, which were not only very good, but remarkably early well-grown chickens. Some of the pullets in the class for Silver Greys were as good as any one could desire so early in the season. In Cochins the Show stood very high; and if we are to take those shown as evidences of the attention still paid to breeding them, the public taste for Cochins is even yet far from a bygone. Mr. Bates, of Harborne, cleared the board of all prizes in the Cinnamon and Buff class with birds of the highest merit and very true to colour throughout, the matching of the pens being also evidently well considered. Mr. Stretch here exhibited a most excellent pen for size and general characteristics, but of feather most difficult to describe. Their general appearance bespoke them to be bred from a cross between Silver Cinnamons and Buffs, as they partook of the peculiarities of both, but far from being true-feathered to either. Still they were remarkably good birds, and shown in faultless condition—lovely fowls to look upon at their present age, but will, if shown at two years old, be completely "grizzled." The dark Cochins were only represented by Brown birds, which are not nearly so attractive a colour as the Partridge-feathered ones. The Hamburgs were weakest in the Golden-pencilled class; but the Silver-pencilled and both the Spangled classes were most meritorious.

Turkeys were shown of excellent quality; and Mrs. Seamons of Aylesbury, quite astonished the inhabitants of the Uttoxeter district by a display of both Geese and Aylesbury Ducks that put everything approaching to competition in the shade. Throngs of visitors crowded around these pens the whole day. The first-prize Geese were Toulouse, the second were truly bred Embdens; and it was difficult to determine priority of position between them. The Aylesburys shown by this lady were just such as she appears always able to send out wherever good premiums are offered. The Rouen Ducks were not only a strong class, but also a very good one. A most unusual feature here was that there was not a single faulty-coloured-billed Duck throughout. A class for Buenos Ayrean Ducks produced great competition. It is, however, well for amateurs to bear constantly in mind that large size here is regarded as the very opposite of a desideratum, however perfect the feather. They should certainly not exceed the size of an ordinary Widgeon, and if smaller so much the better. Some capital White Muscovy Ducks, a pen of Guelderlands, and some excellent Negro or Silky fowls, as "extra stock," closed the rear of this excellent Show.

Every possible care was given to the birds, and we were much pleased to notice that, with one solitary exception, every specimen sent appeared in robust health. Although the railway accommodation to Uttoxeter is not anything like equal to that of the shows that were held respectively at Burton and Tamworth in preceding years, we are glad to find more money was taken at the doors.

GAME (Black-breasted and other Reds).—*Chickens*.—First, J. Bakewell, Draycott Mill (Black). Second, J. Stubbs, Weston Hall, Stafford (Black). Commended, J. Stubbs (Black).

GAME (Any other variety).—First, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth. Second, J. Holme, Knowsley, Prescot (Duckwing).

SPANISH.—First, G. Lamb, Compton, Wolverhampton. Second, J. R. Rodhard, Aldwick Court, Wrington, Bristol. Commended, T. Cliffe, Hanley; E. Fell, Burslem.

DORKING (Coloured, except Silver Greys).—First, J. Hill, Bladon Wood, Burton-on-Trent. Second, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth. Commended, Mrs. M. Seamons, Hartwell, Aylesbury.

DORKING (Silver Grey or White).—First and Second, Lady Bagot, Blithfield Hall, Rugeley (Silver Grey).

COCHIN-CHINA (Cinnamon or Buff).—First and Second, H. Bates, Harborne Heath, Birmingham (Buff). Highly Commended, C. T. Bishop, Lenton, Nottingham (Buff); T. Stretch, Ormskirk (Buff).

COCHIN-CHINA (Brown or Partridge-feathered).—First, T. Stretch, Ormskirk (Partridge). Second, E. Tudman, Ash Grove, Whitchurch, Salop (Partridge). Highly Commended, E. Tudman (Partridge).

HAMBURGH (Golden-pencilled).—First, A. Carter, Poulton-le-Fylde. Second, Rev. R. Roy, Bedwardine Villa, Worcester.

HAMBURGH (Silver-pencilled).—First, J. Holland, Ches'nut Walk, Worcester. Second, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth. Highly Commended, W. Bradley, Diglis Leeske, Worcester. Commended, H. Marshall, Cotgrave, Nottingham.

HAMBURGH (Golden-spangled).—First, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth. Second, J. Leech, Liverpool Road, Newcastle. Highly Commended, T. May, Bloomsbury Street, Wolverhampton.

HAMBURGH (Silver-spangled).—First, Sir St. G. Gore, Bart. Second, E. T. Holden, Walsall. Highly Commended, J. Leech.

TURKEYS.—First, J. Coxon, Freeford, Lichfield. Second, Mrs. P. Wolverstan, Stafold Hall, Tamworth. Highly Commended, J. Faulkner, Bretby Farm, Burton-on-Trent.

GEES.—First and Second, Mrs. M. Seamons, Hartwell, Aylesbury (White and Grey). Commended, J. Faulkner; J. Brassington, Barlaston, Stone (White).

DUCKS (White Aylesbury).—First and Second, Mrs. M. Seamons, Hartwell, Aylesbury. Highly Commended, W. H. S. Kynnersley, Brook House, Mar-chington, Uttoxeter.

DUCKS (Rouen).—First, J. Holme, Knowsley, Prescot. Second, T. R. Hubert, Perrott's Brook, Cirencester. Highly Commended, C. Pease, Southend, Darlington. Commended, J. Bakewell, Moon House, Uttoxeter.

DUCKS (Black East Indian).—First, J. R. Jessop, Beverley Road Hull. Second, F. W. Earle, Edenhurst, Prescot. Highly Commended, Sir St. G. Gore, Bart.

EXTRA POULTRY.—Highly Commended, J. T. Pountain, Cowsley Field House, Derby (Muscovy Ducks); Mrs. Hay, Sudbury, Derby (Guelderlands).

The Judges were George Cargy, Esq., the Cottage, Osmaston Manor, Derby; and Edward Hewitt, Esq., Eden Cottage, Sparkbrook, Birmingham.

MORLEY POULTRY SHOW.

THIS Show, held in connection with the Horticultural and Agricultural Exhibition, took place on the 19th inst.; and, notwithstanding a wet afternoon, was attended by thousands of people from Leeds, Bradford, Halifax, and the neighbourhood, all of whom appeared to take the liveliest interest in the Show throughout.

The Committee exerted themselves in a praiseworthy manner, and succeeded in making the Show a complete success, and everything passed off well.

The show of poultry was not large, yet in many cases the birds were of good quality. Of course the lateness of the season caused the adults to show disadvantageously. A nice Black Red Game stag, though a little too narrow across the shoulders, won first prize for cock of any breed, and a decent Brown Red cock was second. A fair pen of Brown Red chickens were first in their class, and a pretty pen of Black Reds were second. This position would have been reversed but for the cock in the second pen being slightly Duck-heeled. A good pen of Duckwing chickens won, and had the sectional prize for the best pen of Game fowls exhibited awarded to them. A capital pen of Silver-pencilled Hamburgh chickens walked over, and had the sectional prize awarded to them. Bantams, though not numerous, were good in each class, and a capital pen of Black Red Game won the sectional prize. Spanish were very meagre, and, unfortunately, a very good pen of chickens, belonging to Mr. Cannan, were disqualified on account of being in the adult class. A good pen of adult Cochins, belonging to Mr. Beldon, won the sectional prize.

There was a nice show of Pigeons, and a few pens of Rabbits were exhibited.

COCKS (Any Distinct Breed).—First, T. Dyson, Halifax. Second, J. Sunderland, Halifax.

GAME (Black-breasted and other Reds).—First, J. Fell & Sons, Adwalton. Second, H. Beldon, Bingley. Chickens.—First, H. C. Mason, Drighlington. Second, T. Dyson, Halifax. Commended, J. D. Newsome, Batley.

GAME (Duckwings and other Greys and Blues).—Second, J. Fell & Sons. Chickens.—First and Special, W. K. Duxbury, Leeds. Second, J. Fell and Sons.

GAME (Whites and Piles).—First, J. Sunderland. Second, H. C. Mason, Drighlington. Chickens.—Second, H. C. Mason.

GAME (Black and Brassy-winged).—Chickens.—First and Second, J. D. Newsome, Batley.

HAMBURGS (Golden-spangled).—First, H. Beldon, Bingley. Second, G. Farmhill, Carlinghow. Chickens.—First, T. Wilcock, Morley. Second, J. Witby, Farley.

HAMBURGS (Silver-spangled).—First and Second, H. Beldon, Bingley. Chickens.—First, J. Jowett, Morley.

HAMBURGS (Golden-pencilled).—First, H. Beldon, Bingley. Second, S. Smith, Northowram. Chickens.—First, J. Sunderland, Halifax. Second, S. Smith.

HAMBURGS (Silver-pencilled).—First, J. Sunderland, Halifax. Second, H. Beldon, Eingley. Chickens.—First and Special, H. Beldon.

POLANDS (Golden-spangled).—First, H. Beldon, Bingley. Second, W. K. Duxbury, Leeds. Chickens.—Prize, H. Beldon.

POLANDS (Silver-spangled).—First and Second, H. Beldon, Bingley. Chickens.—First and Second, H. Beldon.

POLANDS (Any other variety).—First and Special, H. Beldon, Bingley.

BANTAMS (Gold or Silver-laced).—Prize, H. Beldon, Bingley.

BANTAMS (White).—First, C. Lister, Mirfield. Second, H. Beldon, Bingley.

BANTAMS (Black).—First, H. Beldon, Bingley. Second, C. Lister, Mirfield.

BANTAMS (Any other variety).—First and Second, J. D. Newsome, Batley.

SPANISH.—First, H. Beldon, Bingley. Second, W. K. Duxbury. Chickens.—Prize, H. Beldon.

DORKINGS.—First, H. Beldon, Bingley. Second, G. & S. Taylor, Hunslet. Chickens.—First, G. & S. Taylor. Second, R. Athey, Chapelthorpe.

COCHIN-CHINA.—First and Special, H. Beldon, Bingley. Chickens.—First, C. Lister, Mirfield. Second, H. Beldon.

ANY OTHER VARIETY.—First, W. K. Duxbury, Leeds. Second, H. Beldon,

Bingley. Highly Commended, C. Lister, Mirfield. Chickens.—First, W. K.

Duxbury. Second, H. Beldon.

GESE (Light-coloured).—First, Second, and Special, W. K. Duxbury, Leeds. Highly Commended, J. Dawson, Morley.

DUCKS (Rouen).—First, J. D. Newsome, Batley. Second, J. Ward, Adwalton.

DUCKS (Aylesbury).—First, H. Beldon, Bingley. Second, W. Barnett, Holbeck.

DUCKS (Any other variety).—Prize, C. Lister, Mirfield.

TURKEYS.—Prize, C. Grosvenor, Middleton.

PIGEONS.—**Carriers**.—First, H. Beldon, Bingley. Second, J. Firth, jun., Dewsbury. **Owls**.—First, H. Beldon, Bingley. Second, T. H. Sagar, jun., Leeds. **Turbits**.—First, H. Beldon, Bingley. Second, J. Firth, jun., Dewsbury. **Barbs**.—First, J. Firth, jun., Second, H. Beldon. **Tumblers**.—First, H. Beldon. Second, T. H. Sagar, jun. **Fantails**.—First, M. Spedding, Dewsbury. Second, — Naylor, Armley. **Powters**.—Prize, H. Beldon, Bingley. **Nuns**.—Prize, M. Spedding, Dewsbury. **Jacobins**.—First, J. Ross, jun., Stump Cross. Second, J. Firth, jun., Dewsbury. **Common**.—First, M. Spedding, Dewsbury. Second, T. Barron, Morley.

RABBITS.—Prize, Rev. W. Thorold, Middleton Parsonage.

The Judges were Messrs. R. Teebay, Fulwood, Preston, and H. M. Julian, Whitefriargate, Hull.

POULTRY AT THE DERBY AGRICULTURAL SOCIETY'S SHOW.

(From a Correspondent.)

THE annual Exhibition of the Derbyshire Agricultural Society was held at Derby, in the cattle market, on Friday September 16th. The poultry was not the least attractive feature in the Show, and the improvement in point of breed, as well as number, was very manifest, there being nearly one hundred pens exhibited.

In Coloured **Dorkings** Mr. Hill showed a very fine pen, the Countess of Chesterfield being second. Mr. Faulkner's Whites, which were the first at the Sparkenhoe Farmer's Club, well merited the same honour here, although there was none to oppose. **Spanish** showed very well, the first-prize birds being excellent, as well as the cock in the second-prize pen. The **Game** classes, as a whole, were very good, Mr. Spencer's Whites being everything that could be desired. In **Hamburgs** Mr. Campion's Silver-pencilled well deserved the honour they obtained. Mrs. Hurt carried off the premium for **Dorking** chickens, and the Countess of Chesterfield was second. Many of the Game chickens promised well. The first-prize **Cochin** pullets were splendid birds, but the cock was not their equal. Whites were second with a capital pen.

For **Rouen Ducks** there was no competition; but the second-prize Aylesbury were very large, though rather short of breed compared with the first. **Geese** and **Turkeys** were good, though the entries were few. Last, though not least, was Mr. Pountain's pen of White Muscovy Ducks, which deservedly received a high commendation as extra stock.

DORKINGS (Coloured).—First, J. Hill, Bladon Wood. Second, Countess of Chesterfield. Highly Commended, J. Hitchman, M.D., Micklesover. Commended, J. Faulkner, Bretby Farm. Chickens.—First, Mrs. Hurt. Second, Countess of Chesterfield. Commended, J. Faulkner.

DORKINGS (White).—Prize, J. Faulkner.

SPANISH.—First, J. T. Pountain, Cowsley Field House. Second, H. Darby, Derby.

GAME (Dark-breasted).—First, J. Bakewell, Dracott Mill, Sudbury. Second, W. Thorpe, Thulston. Highly Commended, G. Statham, Sudbury. Commended, J. Bakewell. Chickens.—First, Mrs. Hay, Sudbury. Second, T. S. Radford, Egginton. Commended, J. Milnes.

GAME (White or Pile).—First, C. Spencer, Thulston. Second, J. Milnes, West Hallam. Commended, H. King, Melbourne.

HAMBURGS (Gold-pencilled).—First and Second, P. W. Bowne, Bull Bridge, Crich. Commended, C. Spencer.

HAMBURGS (Gold-spangled).—First and Second, F. Camp, Etwall. Commended, S. W. Cox, Spondon; J. Faulkner.

HAMBURGS (Silver-pencilled).—First, T. Campion, Brailsford. Second, G. Statham.

HAMBURGS (Silver-spangled).—First, Miss A. M. Hurt, The Knoll, Littleover. Second, Mrs. Hurt, Alderwasley. Commended, J. Langley, Mickleton; H. Darby.

COCHIN CHICKENS.—First, J. T. Pountain (Buff). Second, H. Wallis, Derby (White). Commended, J. Hitchman, M.D. (Buff).

DUCKS (Rouen).—Prize, R. Cowley.

DUCKS (Aylesbury).—First, J. Faulkner. Second, J. Hitchman, M.D. Highly Commended, W. Harding.

GEES.—First, W. T. Cox. Second, J. Hitchman, M.D. Commended, R. Cowley, Bredsal; J. Faulkner.

TURKEYS.—First and Second, J. Brough, Langley.

EXTRA STOCK.—Highly Commended, J. T. Pountain (Muscovy Ducks).

mended, Mrs. M. Seamons. *Rouen*.—First, J. Nelson. Second, J. Robinson, Garstang. Highly Commended, C. Moore; J. Robinson; E. Leech. *Any other variety*.—First, C. W. Brierley, Middleton. Second and Highly Commended, T. Statter.

GOSLINGS (Any variety).—First, J. Southern, Kenyon. Second and Highly Commended, D. R. Davis, Knutsford.

TURKEYS.—First, R. J. Wood, Manchester. Second, C. W. Brierley. Highly Commended, E. Leech; D. R. Davis, Knutsford.

POULTRY SELLING CLASS.—First, H. Carter, Holmfirth (Black Polands). Second, R. Goodwin, Middleton (Black Hamburgs). Third, T. Burns, Abram, Wigan. Highly Commended, Miss A. Bamford.

PIGEONS.—*Tumblers* (Almond).—First, H. Yardley, Birmingham. Second, P. Eden, Salford. *Carriers*.—First and Second, P. Eden, Salford. *Pouters*.—First, E. Brown, Sheffield. Second, P. Eden. *Jacobins*.—First, H. Yardley, Birmingham. Second, E. E. M. Royds, Rochdale. *Fantails*.—First, J. W. Edge, Birmingham. Second, H. Carter. *Owls*.—First, J. W. Edge. Second, J. Walsmsley, Falsworth. *Nuns*.—First, H. Clegg, Oldham. Second, J. W. Edge. *Any other variety*.—First, C. J. Samuels, Manchester (Trumpeters). Second, P. Eden (Barbs).

RABBITS.—First and Second, R. Anderson, Stand, Pilkington.

JUDGES.—Poultry : Mr. R. Teebay, Fulwood, Preston; Mr. J. H. Smith, Skelton Grange, near York. Pigeons and Rabbits : Mr. E. Slack, Newton Heath, near Manchester.

MIDDLETON AGRICULTURAL SOCIETY'S POULTRY SHOW.—SEPTEMBER 22ND.

GAME (Black-breasted and other Reds).—First, J. Wood, Moat House, Haigh, near Wigan. Second, J. Fletcher, Stoneclough, near Manchester. Third, T. Dyson, Fellon Lane, Halifax. Highly Commended, Capt. H. Heaton, Lower Broughton, Manchester; J. Feil, Deighton, near Leeds; J. Firth, Lily Lane, Halifax. *Cockerels*.—First, T. Dyson. Second, J. Wood. Highly Commended, T. Statter, Stand, near Bury; J. Firth.

GAME (Any other variety).—First, J. Fletcher, Stoneclough (Pile). Second, E. Aykroyd, Birlington Road, near Bradford (Duckwing). Third, J. Fletcher (Duckwing). *Cockerels*.—First, H. Thompson, Milnthorpe (Pile, white legs). Second, W. R. Duxbury, Leeds (Duckwing).

GAME (Any variety).—Cup, J. Crossland, jun., Wakefield. Second, J. Wood, Haigh, near Wigan (Brown Red). Third, E. Aykroyd, Bradford (Duckwing). Highly Commended, J. Fletcher, Stoneclough (Piles); J. R. Rodbard, Aldwick Court, Wrington, near Bristol (Duckwing); J. Wood; H. Thompson, Milnthorpe. Commended, J. Eaves, Knowsley; T. Statter, Stand, near Bury; C. W. Brierley, Middleton; T. Dyson, Halifax; W. K. Duxbury, Leeds; Capt. Heaton.

SPANISH.—First, E. Brown, Sheffield. Second, W. Cannan, Bradford. Third, J. Topp, Halswell Moor. *Cockerel*.—First, W. Cannan. Second, E. T. Holden.

DORKINGS.—First, J. White, Warlaby. Second and Third, E. Smith, Middleton. Highly Commended, C. W. Brierley. *Cockerel*.—First, S. Harrop. Second, J. White. *Pullets*.—First, E. Leech, Rochdale. Second, J. White. Highly Commended, E. Smith.

BRAHMA POOTER.—First and Third, H. Lacy, Hebden Bridge. Second, T. Statter, Bury. *Cockerel*.—First, T. Statter. Second, H. Lacy. Highly Commended, Mrs. M. Seamons, Hartwell. *Pullets*.—First and Second, H. Lacy. Highly Commended, E. T. Holden, Walsall; E. Leech.

COCHIN-CHINA (Any variety).—First, T. Stretch, Ormskirk (Partridge). Second, Captain H. Heaton (Buff). Third, J. Nelson, Manchester (Buff). Highly Commended, C. Kershaw; J. Crossland. *Cockerel*.—First, C. E. Ridesdale. Second, Captain H. Heaton, Manchester. Highly Commended, C. Kershaw. *Pullets*.—First, Captain H. Heaton (Buff). Second, W. A. Taylor, Manchester. Highly Commended, G. H. Wheeler; J. T. Wellens, Middleton.

HAMBURG (Gold-pencilled).—First, C. M. Royds, Rochdale. Second and Third, J. Fielding, Newchurch. Highly Commended, T. Wrigley, Middleton. *Cockerel*.—First, T. Burns, Wigan. Second, J. Preston, Bradford. *Pullets*.—First, J. Wrigley. Second, S. Smith, Northowram. Commended, Mrs. H. Sharp, Bradford.

HAMBURG (Silver-pencilled).—First, J. Robinson, Garstang. Second, J. Preston, Old Bough, Ollerton, near Bradford. Third, H. Beldon, Gilstead, Bingley. *Cockerels*.—First, H. Charnock, Church, near Accrington. Second, D. Ilkingworth, Burley, near Oley. *Pullets*.—First, Mrs. H. Sharp, Bradford. Second, E. Smith, Middleton.

HAMBURG (Gold-spangled).—First, T. Scholes, Chadderton. Second, J. Sugden. Third, J. Roe, Hedfield, near Manchester. Commended, T. Ogden, Chadderton. *Cockerels*.—First, J. Buckley, Tainton, near Ashton-under-Lyne. Second, Hepworth & Coldwell, Norridge, Holmfirth. Commended, Messrs. Saul & Co., Boarshaw. *Pullets*.—First, J. Chadderton, Old Lane, near Hollinwood. Second, J. Ogden, Chadderton. Highly Commended, J. Lancashire, Heaton.

HAMBURG (Silver-spangled).—First, J. Robinson, Garstang. Second, Messrs. Saul & Co., Boarshaw, Middleton. Third, M. Isherwood, Bank Top, Radcliffe. Highly Commended, J. Fielding; J. Kay. *Cockerels*.—First, J. Lancashire, Tong Lane. Second, J. Collinge, Middleton. Highly Commended, J. Ogden, Middleton. *Pullets*.—First, M. Isherwood. Second, J. Hilton, Middleton. Highly Commended, T. Collinge; J. Lancashire.

HAMBURG (Black).—First, H. Beldon, Gilstead, Bingley. Second, R. Battersby, Heywood. Third, J. H. Lord, Little Green, Middleton. Highly Commended, R. Goodwin, Middleton. *Cockerels*.—First, J. H. Gardener, Hollinwood. Second, J. H. Lord. Highly Commended, J. Hope, Oldham. *Pullets*.—First, E. Partington, Middleton. Second, R. Battersby, Heywood. Highly Commended, T. Jaques, Bottom Barrowfields, Middleton; R. Lancaster, Sandy Lane, Tonge.

ANY VARIETY (not included in the Classes).—First, H. Carter, Upper Thong, Holmfirth. Second, H. Beldon, Gilstead (Silver Polands). Third, W. Barber, Ovenden, near Halifax (Andalusian). Highly Commended, W. Fairbairn, Wendle, near Rochdale (Cuckoo Creels). *Cockerels*.—First, H. Beldon, Gilstead (Silver Polands). Second, S. Farrington, Chat Moss, Ashley, near Manchester (White-crested Black Polands). *Pullets*.—First, S. Farrington. Second, W. Barber (Andalusian).

BANTAMS (Game).—First, J. W. Morris, Rochdale. Second, J. Crosland, jun., Wakefield. Third, J. W. Morris. Highly Commended, J. Crosland, jun. *Cockerels*.—First and Second, C. W. Brierley, Middleton (Black Red and Brown Red).

BANTAMS (Any other variety).—First, C. Walker, Halifax (Gold-laced). Second, H. Beldon, Bingley (Black). Commended, T. C. Harrison, Hull. *Cockerel*.—First, H. Beldon (Silver-laced). Second, C. W. Brierley.

DUCKLINGS.—First, J. Hartley, Rochdale. Second and Highly Com-

KNOTTY POINT.

POULTRY SHOW SWEEPSTAKES.

In our Journal of the 30th ult., page 183, we gave the details of a case argued in the Suffolk County Court. The Judge of that Court, John Worledge, Esq., delivered his judgment in the case on the 19th inst., and we have been favoured with the following copy of his judgment.

PAYNE v. J. DALLENGER AND WHISSTOCK.

This was an action brought by Mr. Payne, who is managing clerk to Mr. Gudgeon, of Stowmarket, to receive from the defendants the small sum of 8s.; but though the sum be small, Mr. Payne alleged that the case involved a matter of principle, but to my mind it seems to involve a good deal more feeling than principle; but however that may be, I must decide it according to the best of my judgment.

The case arose in the following way:—On the 26th and 27th of May last, there was a poultry show at Woodbridge, under the auspices of the Suffolk Poultry Society, of which defendants were the Secretaries, and among the events, to use a sporting phrase, that were advertised to come off, was a sweepstakes for "Dorking Cocks," which was thus set forth in the programme of the Show: "Dorking cock class, a sweepstakes of 7s. 6d. each will be opened for Dorking cocks of any colour, the stakes to be disposed of (after deducting 5s. from each entry for hire of pens, &c.) in the same proportions as in the Game cock class." The plaintiff having a Dorking cock, of which I suppose he entertained a high opinion, entered him for the above sweepstakes, and at the same time remitted defendants the sum of 7s. 6d., according to the terms of the printed programme as shown above quoted. Mr. Payne entered his Dorking cock on the 7th of May, which was the last day for entries, and there was no other entry at all for the Dorking cock sweepstakes; but Mr. Payne had no notice of the fact, and in due time sent his bird to Woodbridge, where he was duly exhibited with other feathered bipeds then present. There being no other entry for the Dorking cock sweepstakes, the prize Mr. Hewitt awarded Mr. Payne. The prize in sweepstakes was 2s. 6d., and 2s. 6d. was accordingly sent to Mr. Payne by the defendants, and received by him. But Mr. Payne was not satisfied with that, and has brought this action to recover 8s. more, which I understand is thus made up—3s. for the expenses of sending the cock to Woodbridge, and 5s. the residue of the 7s. 6d. paid by Mr. Payne when he entered his bird. The first Mr. Payne contended he was entitled to recover from the defendants, because he said it was their duty as soon as they knew there was no other entry for the Dorking cock sweepstakes, to have given him notice of the fact, so as to have prevented the necessity of his sending his bird to Woodbridge, and that not having done so they were liable to refund to him the expenses of sending it; and the 5s. Mr. Payne claimed upon the ground that there being only one entry, there was, strictly speaking, no Dorking cock sweepstakes at all, and that, therefore, he was entitled to recover back the whole of the 7s. 6d. he had paid upon the faith of there being a sweepstakes.

Now, it is clear that all entries are made subject to the

rules and regulations of the Show, and, indeed, in the form of entry signed by Mr. Payne, it is expressly stated that his entry was so made. That being so, it is in my opinion a sufficient answer to Mr. Payne's claim as to the 3s., and there is nothing whatever in the rules and regulations requiring the defendants to give Mr. Payne the notice he contends he was entitled to, and, therefore, his case as to the 3s. fails. And with respect to the 5s., the residue of the claim, the following of the rules and regulations appear to me material to the decision of the case—viz., "All exhibitors will be required to pay 5s. per pen for each class exhibited, which shall include coops, food, attendance, &c." And Rule 10, "Persons entering poultry and failing to send the same to the Exhibition will forfeit the entrance for each pen, &c., so left vacant." Now coupling the rules I have quoted with the words in the programme of the Dorking cock sweepstakes (after deducting 5s. from each entry, for hire of pens, &c.), it is, I think, perfectly clear that of Mr. Payne's 7s. 6d., 2s. 6d. only was his stake in the sweepstakes, and that the remaining 5s. became absolutely and irrevocably appropriated to the hire of pens, &c.. The &c. being large enough and general enough to include, and probably also intended to include, a contribution to the general expenses of the Show; and the tenth rule also shows, in my opinion, that whether the birds entered were exhibited or not, the 5s. at all events were not to be returned, that being, in fact, the entrance fee for each entry.

Now, that being, in my opinion, the result to be deduced from the rules, it is quite unnecessary for me to decide the knotty point as to whether there was, in fact, a sweepstakes for Dorking cocks or not; because if there was, Mr. Payne won it, as was decided by the Judge of the Show, and has received the prize. If there was not, Mr. Payne has equally got back his stake—viz., the halfcrown, which is all that he was entitled to on the failure of there being any Dorking cock sweepstakes, if failure there was.

I think, therefore, the defendants have paid Mr. Payne all that he was entitled to receive under any aspect of the case, and the judgment of the Court must be for them; but as Mr. Dallenger's letter* of May 30th was not exactly a fair statement of the facts, and was calculated to produce a wrong impression on Mr. Payne's mind, each party must pay their own costs.

JUDGMENT FOR THE DEFENDANTS WITHOUT COSTS.

* [COPY OF LETTER REFERRED TO.]

"Ecclesia Chambers, 30th May, 1864.

"DEAR SIR.—I enclose you 2s. 6d. in stamps for prize Dorking cockerel sweepstakes. There was only one entry, and we retain 5s. for the pen.

"Your cock had the privilege of competing with the Dorking cocks (Class 12) against Mr. Frost, Mr. Lingwood, and Mrs. Blair, but Mr. Frost beat you. We thought it only fair, as there was only one entry for sweepstakes, that you should be allowed to do so, and it was done, but without success.

"Yours truly, 'JNO. DALLENDER.'

"Mr. H. Payne, Stowmarket."

TUMBLERS NOT FLYING.

ABOUT four months ago I purchased half a dozen high-flying young Tumblers, which when I turned out flew so high as to go out of sight, and they generally were about an hour before they descended; but since that they seem to have been gradually growing worse and worse in their flying, and now they never fly more than ten or fifteen minutes, yet I know that those belonging to the vendor fly for two or three, and sometimes four or five hours without alighting, and he said that mine would do the same when they grew older. Will you tell me the reason of their not doing so, and the remedy? I only let them out once a-day, and sometimes not at all, so that it cannot be through having too much liberty. Last week I shot half a dozen commoner ones for the table, and they being in very good condition, I thought perhaps I might be feeding the Tumblers too well, so I gave them less food, but as yet it has made no difference.—A SUBSCRIBER.

[I think that you allow your flying Tumblers to associate with common Pigeons, and as the old proverb asserts, "Evil communications corrupt good manners," your Tumblers learn to imitate the habits of the common birds. I would advise you either to kill off all the common Pigeons, or to keep them confined until the Tumblers have had their daily

fly. If your Pigeons are too fat more exercise will reduce them to proper condition. Weather permitting, make them fly every day, and keep them to it until they are again in good training, and then be careful that they do not relapse into idleness. They cannot be fed too well when they are in training, and have regular daily exercise. Peas, Indian corn, and lentils, are variously recommended as the best food for flying on, and a little hempseed just at starting; but the Pigeons must not be turned out too full. You will, perhaps, have some trouble to make the Pigeons keep up at first, but you must not expect to succeed unless you attend them regularly.—B. P. BRENT.]

WINTERING A CUCKOO.

I PERCEIVE one of your correspondents is very anxious to preserve through the winter, alive and in health, a young cuckoo which he has reared this summer.

I have not myself any fear that this may be easily effected by proper care, as I, when a youth, kept both the cuckoo and the corncrake the year round. I had both when quite young. The cuckoo I fed at first on raw meat and boiled eggs, of which it always ate ravenously during the time it was in my possession—viz., until the 26th of April, being very nearly a year old. It then escaped by the neglect of a servant, its health and plumage being perfect, for singularly enough, it moulted to adult feather during February.

The meat it preferred was either sheep's heart or sheep's kidney cut into moderate-sized pieces, of which it consumed considerable quantities. Until the November of 1828 it had the free range of a large back unoccupied attic. Severe weather then setting in, this bird was placed in a throstle's wicker cage near the fire in the kitchen, and as it at that time seemed very listless and drooping, possibly in part from being more closely confined, it was then supplied with an occasional treat of "mealworms" from a flour mill in the neighbourhood. The moment it saw mealworms it ate heartily, however disinclined to motion previously. The dull habits of this bird continued only during the really cold months of winter, for in February it was again set at liberty in the room with its old companion the corncrake, and flew about as happily as ever. During the whole time it was in my possession it never once uttered the well-known cry from which it takes its name, but frequently when flying about the room made the exceedingly rapid monotonous noise, customary to this bird at spring time, when flying in the open country. They are a very objectionable bird to keep on account of the nature of their excrement.

The corncrake was a truly lively and most interesting pet, and was so young as to be only covered with black down when I obtained him. He was at first fed on chopped eggs, boiled hard, mixed with cheese and meat, and eventually he went on well with chopped bread and cheese alone. He was always in motion, for his hearing was so singularly acute that to approach him without his knowledge was impossible. I kept him nearly three years, and he almost invariably "cracked" before rain. He was jokingly called my "weatherglass," and mostly proved a very correct one. He had a turf of grass whenever it could be readily obtained, and was especially fond of grasshoppers and woodlice, and would leave any other food to seize a stray mealworm, if by chance his cuckoo-friend happened to let one fall. He was a great favourite of all the family during the whole time we had him, and never evinced the sullen disposition of the cuckoo, for he would follow us when spoken to—in fact he seemed determined to cultivate acquaintance with every one. His plumage was, except at natural intervals of time, of as brilliant a character as though at liberty, and strong were the expressions of regret, when one morning he was "found dead" without any apparent indisposition beforehand.—EDWARD HEWITT, Sparkbrook, Birmingham.

MANAGING BEES ON THE NATURAL SYSTEM.

SOME time ago you were good enough to insert a letter of mine on the subject of bee-keeping, wherein I expressed my intention of abandoning the "scientific" system for a more

natural one based on the habits and instincts of the bee. It will interest your readers to learn from my experience how they may turn a general disappointment into a pleasurable and profitable amusement.

The great feature of all controversy on the subject is how to prevent swarming. To this end all kinds of elaborate hives have been invented, books written, plans proposed, and controversies engaged in. My four-years experience with Neighbour's, Taylor's, Stewarton, and other hives convinces me that it is impossible to prevent swarming except by one method, that of cutting out the queen's cells—a difficult, delicate, and, to inexperienced or timid persons, dangerous operation. So strong is the colonising instinct, that all the plans of space and ventilation that can be adopted will not retain the swarm at home if queen bees are allowed to be hatched; whilst the adoption of such plans invariably results, as far as my experience goes, in injury to the young bees and the retardation of the honey crop. The fact that swarms issue from large hollow trees, garrets, church roofs, &c., where additional accommodation for comb-building is amply provided sufficiently proves the point that by giving space you cannot prevent a swarm from issuing. Having once made up my mind on the subject, I abandoned the system, the constant results of which had been lost time, lost honey, and continual annoyance.

The experience of most amateurs is, I venture to think, one of similar disappointment. I have adopted what seems to me a more natural and sensible plan. I now encourage swarming, hive the swarms, unite them if 'casts,' let them work all the summer, and in the autumn take the honey, destroying such hives as I think too weak for the winter, leaving strong stocks from which only supers have been taken for next season's supply. I also avoid as much as possible, in contradiction to my previous mode, interfering with the bees. They regulate their own temperature and time of swarming far better than we can do; and they will work to greater advantage if not inspected and intruded upon too much in the honey season.

Acting on these principles, the following is my result for 1864. From five stocks I have had eight swarms, one of which I gave away; another, after being hived in a Stewarton, took wing and settled in an old pollard; and two casts I united. From No. 1, an old stock, after two strong swarms had issued, I took 4½ lbs. of honey, and destroyed the bees, as I wanted to change the comb. From No. 2 I took a super of honey weighing 11½ lbs. From No. 3 I took 15 lbs. Nos. 2 and 3 swarmed together; and so large was the united swarm that I was obliged to put on a super the same night. From these boxes I took 36 lbs. From No. 4 I took a large super with 20 lbs.; and from its prime swarm, which I have since destroyed, I took 18½ lbs. Two casts from Nos. 3 and 4 were united in July, and having been lately fed, now form a strong stock for next spring. From No. 5 I took 11 lbs., and destroyed the old stock, keeping its prime swarm. I have just destroyed the swarm from No. 1 in the tree, and obtained 16 lbs., making a total of 132½ lbs., whilst I retain five strong stocks amply provided with food for the winter.

Part of this success arises from the season; but the chief result has arisen from my allowing nature, with a very little assistance from art, to have its own way.—A BEE-MASTER IN ESSEX.

FOUL BROOD IN YORKSHIRE.

I SEND you herewith a small box containing a sample of comb taken from one of my hives. I fear there is little doubt of its being virulent foul brood, but shall esteem it a favour if Mr. Woodbury will kindly inform me whether it is so.

The stock was driven late last autumn into a Woodbury hive, and had to be fed. This spring I found four of the combs covered over with fungus, and completely deserted by the bees. I removed these, but found no brood in the cells, but only mouldy pollen. I supposed that they were fed too late to seal over the cells, and that evaporation in the winter had caused the growth of mould.

They have since increased in numbers, but have not swarmed, nor yielded any honey; and to day, on examining

the combs, I found brood in nine frames, some of the cell covers perforated, others not so, but nearly all with flattened tops, and containing brood more or less decomposed.

In the same shed I have a Ligurian swarm of May, this year, which has done very well, yielding me a super of 25 lbs. of fine honey. I am very sorry to find that it has received the infection, though at present it exists to a much smaller extent than in the other stock.

Should Mr. Woodbury's verdict bear out my fears, I propose to unite the bees of the two stocks with the Ligurian queen, which is a fine one, and drive them into a hive with empty comb in it, giving them three days quarantine in an intermediate-hive, and then feeding them for the winter. Will this be my best course? and shall I need to confine the queen longer than the workers, at this season of the year?

I have also enclosed a sealed queen cell which I took from a hive belonging to a friend, which has swarmed twice, and since been robbed and deserted. It appears to be empty; if so, have the bees sealed it over again after the queen has left, or what has become of the royal larva?

Is the honey from diseased stocks fit for human food, and if not to what use can it be applied?—C. D.

I regret to say that the sample which accompanied this letter is unquestionably foul brood, and I should think of a very virulent type, since I never saw any that presented a worse appearance, whilst it appears to have communicated itself by infection to a neighbouring stock.

If "C. D." either possesses or can procure another healthy stock to which he can give the Italian queen, I should advise his doing so, and destroying both the diseased colonies, in preference to attempting their union and cure by the means he describes: and for these reasons—the cure of foul brood is always very uncertain at the best, and at this advanced season I fear the chance of success would be small indeed. Added to this, there is so much difficulty in uniting Ligurian to common bees, that I believe the Italian queen would run quite as great a risk during the fusion of the two diseased colonies, as she would by being placed at the head of a healthy stock of common bees. I therefore consider it better to follow the course which I have pointed out, and by which the hope may be entertained to entirely get rid of the disease.

Honey taken from foul-breeding stocks may be safely eaten, or made use of for any other purpose, except that of feeding bees.

I believe a queen had hatched out of the royal cell sent, but the cell cover, remaining attached on one side as by a hinge, had closed after the departure of its tenant, and thus appeared as though it had remained perfectly intact. This is no very unusual occurrence.—A DEVON-SHIRE BEE-KEEPER.]

OUR LETTER BOX.

LEG WEAKNESS (Subscriber).—Your Cochin-China cockerel, being a heavy bird, showing weakness in his hocks, may recover from that in the course of another month or two. Feed chiefly on bruised oats, give bread sopped in beer two or three times weekly, and four grains of citrate of iron daily until the bird shows more strength in his legs.

WEIGHT OF A DORKING COCK (W. S. P. B.).—As a rule, a Dorking cock is making satisfactory growth when he weighs as many pounds as he is months old. If, therefore, yours has made 6 lbs. in four months, he is unusually good. It is quite unimportant that he has red earlobes. Feed him generously, and let him have his liberty.

BUYING BANTAMS (Idem).—The proper time for buying a Silver Sebright Bantam hen is when she is clean moulted, about two months hence. The surplus stock of most breeders is sold next month. A good hen is always worth twenty-five or thirty shillings.

CAPONISING (W. R. C.).—We know of no book that treats on caponising. The custom has so much fallen into disuse, that there are few, or no men, who can perform the operation. It is not worth doing. The sufferings of the birds, the numbers that die, and the inferiority of the birds compared with young cockerels, which may be made as large, while they are younger and more delicate, have caused the practice to be discontinued.

PACKING EGGS FOR TRANSPORT (A. J. H.).—The proper way to pack all eggs intended for sitting is to use moss. Cover the bottom of the basket with it, roll up every egg separately in moss, so that it is completely enveloped, then put it in the basket, small end downwards. Fill up in this way till there is room for no more. Then put a layer of moss again, and pack another row of eggs. Continue till the basket is full, and be careful to top up so tightly that no egg shall move out of its place whilst travelling.

IVY NOT POISONOUS TO SHEEP, &c. (E. J. J.).—Sheep eat Ivy with impunity. The Duke of Richmond at Goodwood, and Mr. Elliman near Lewes, have first-class flocks of Southdown sheep. Clipping the wings of hens has no bad influence on their laying powers. Age reduces that power.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 62.2°, and its night temperature 43.2°. The greatest heat was 80° on the 4th, 1859; and the lowest cold, 28°, on the 5th, 1850; 8th, 1852; and 9th, 1849. The greatest fall of rain was 1.06 inch.

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 1.

ANY years have passed away since my intense love for the vegetable world centered itself in "hardy Ferns :" I loved them, not because they were the fashion, but because they pleased me — pleased me in a manner that even wild flowers failed to do. I think one reason for this was that I felt the study of Ferns was within my capacity, I could, as it were, measure the length and

breadth of what was necessary for the knowledge required — no hard books, no very unpronounceable names ; but what was far better, I saw in the distance long walks in pleasant places with cherished friends, a little speculation, a little argument, and a great deal of innocent enjoyment. Then the habits of the Ferns pleased me ; the tall graceful Lady Fern hiding herself away in some sequestered nook — the hardier *Filix-mas* shooting up tall and straight, proud of its strength and size — the pleasure-loving little *Septentriionale* basking in the very eye of the sun — the shy *Ruta-muraria* scorning any home or companions but those of its own seeking, and quickly pining away in a land of strangers — the *Scolopendrium* revolving in their rich variety of form, each with a separate charm, yet together forming one of Nature's loveliest groups.

So I brought to the study of Ferns a lover's heart, and like other lovers I have had many ups and downs in following the fair objects of my choice, and my huge Fern-book stands like a gallery of departed misses, each labelled with the fond name of a wild imagination ; a diminutive frond of *Lastrea dilatata* appears boldly as "*Dryopteris!*" unmitigated *Filix-mas* does duty as "*Lastrea cristata!*" *Oreopteris* alone is right. Oh ! what happy days does my old Fern-book recall ! — what pleasant wanderings by banks and braes, by rock and river ! Each Fern has its own separate existence in my memory. I see once more the little brawling *Gwendryth*, from whose banks I drew my *Dilatata* to flaunt for a time under its fictitious character ; I hear the hearty welcome of the Welsh tailor, whose weather-beaten cottage stood beneath a weeping Birch tree by its side, where the poor fellow earned a scanty living for his consumptive wife and many children. From that first visit my mind travels to the last ; the gentle voice is hushed, the poor bed of straw empty, and lying in an inner room on a flower-bestrewed coffin is the patient sufferer at rest for ever. The Welsh poor are like none other ; I have wandered

amongst many people, been greeted as a friend by many, but never so gratefully, so gracefully, as in the lowly cottages of Wales.

My first *Oreopteris* was found in a wild mountain spot a few miles from Chepstow. I went in search of it with a frond from a true plant in my hand. I remember the search as if it were but yesterday — how gallantly I plunged into the Devil's Punch-bowl, where, I was told, the *Oreopteris* drank the dews of heaven ! how diligently I crushed every Fern I found there, till the sweet lemon scent that escaped told me my search was over, and that the frond in my hand, with its tidy rows of spore-cases, guarding the leaflets like rows of little soldiers, and its bleached-looking stalk, was my favourite *Oreopteris*. There are many common Ferns to be found about Chepstow and the beautiful banks of the Wye. I found the *Ceterach*, *Asplenium trichomanes*, divided forms of *Hart's-tongue*, &c. ; but I also found *Tintern Abbey*, that most perfect of all English ruins, and Raglan Castle, and I would say, Let no man think he has seen a sunset till he has seen one from the tower of Raglan. Yet it is a cockney sort of sunset ! for it is po inted out to you with the utmost precision, every shade of colouring expatiated upon, till you turn away with an angry feeling as if some one had spoken of your own beauty in a rude unfeeling manner ; yet for all that, one looks in a glass again, and I hope to see a sunset from Raglan tower once more.

From Chepstow I passed on to South Wales, where for several months I carried on my somewhat wild researches much as a mariner without a compass might do ; but my "ignorance (most certainly) was bliss," and by the magic wand of imagination each day's discoveries were transformed into gems of rarest value. I have never altered these fictitious names in my book, they bring me such happy memories of bygone days ; they are a journal in which nothing but scenes of beauty and pleasure are recorded. This frond was gathered at Dynevor Castle, put aside for the minute while I hammered away at the rocks ; for I carried on a little desultory wild geology as well as botany, and Dynevor is a famous place for both. As I look at this *Asplenium ruta-muraria* I am once more scrambling down the old broken mud wall, strongly savouring of pigs, where it had made its home, far down to some famous sand-burrows from which I gaze on the treacherous Cefn Sidan stretching far out into the blue waters towards Tenby. As I watch I see two vessels bearing down on each other ; they pass and seem to pause ; a boat is lowered from both, and then I see the smaller of the two vessels slowly sink down lower and lower till only her mast is above the sea. I hasten home, and after a while of suspense hear the good news that no life was lost.

Another Fern takes me to a Welsh wedding, where I had been "bidden" by a printed invitation in these words :—" As we intend to enter the matrimonial state on Thursday, the 9th day of June next, we are encouraged by our friends to make a BIDDING on the occasion, the same day, at the young woman's father's house, in the village of L——, at which time and place the favour of

your agreeable company is humbly solicited, and whatever donation you may be pleased to confer on us then will be thankfully received, warmly acknowledged, and cheerfully repaid whenever called for on a similar occasion, by your obedient servants, David Jones, shoemaker, and Hester Morris." What a wedding it seemed to be, as I gazed for a few minutes on the soberly merry scene! What an incongruous heap of presents the bidding had collected—chairs, tables, a clock, cups, jugs, pots and pans! What a Babel of voices! and what dancing! Nothing rude or boisterous but the fiddle, which gave spasmodic attempts to be jocund only ending in a growl, to which one young dancer after another trod a sedate and solemn measure, while the elders exclaimed, "Look! see what a grand dance! Yes, yes, it is fine." Thinking the "Sassenëg" might be a hinderer of mirth, I departed.

This frond of *Asplenium marinum*, measuring $1\frac{1}{2}$ foot, I consider the gem of my old book; it bears a look of learning about it; it reminds me that at this time I invested half a guinea (its then price), in Moore's "Popular History of British Ferns," and that it has been quite worth its cost to me. In the local distribution of *Asplenium marinum* I found mentioned, "Cliffs between Tenby and Saundur's Foot." I tremble when I think of those cliffs. Armed with a bamboo 15 feet long with a knife tied on the end, I sallied forth one day in search. By using the utmost dexterity the bamboo was carried safely over the ferry; but the land passage was not so easily accomplished, the retreating tide leaving, not sand or shingle, but huge boulders of slimy stones and rock, covered with various Algae, each more inimical to walking than the other, while little pools of water with tiny crabs in them seemed lying in wait at every step. I measured the bamboo with my eye, and grasped it fairly in the middle, but now its head would entangle itself in the seaweed ahead, its poor body starting up like an overstrained bow, threatening to precipitate me backwards; and now it would bury itself in the sand, from which, at an unwarv jerk, it flew madly in the air, dancing the knife about in dangerous fashion.

Yet, how beautiful was that coast! Cliff after cliff broken into every fantastic form, with masses of trailing plants adorning them, and here and there, high and dry, a bit of sand from which poor dried-up grass issued, sent, as it seemed, to bear the tender weight of pink and white *Convolvulus*. The white ripples of the retreating tide returned for a moment to gaze upon the intruders, while far overhead a solitary bird went sailing into the blue distance, sending forth a plaintive cry to its lost fellows. And in some little cave amidst this unbroken solitude I was to see for the first time my friend *Asplenium marinum*, and at last I found it! A damp dripping cave it was, with no bit of dry rock to promise a safe perch if the waves caught you; steep cliffs around with no escape; but hanging here and there above my reach, even with the bamboo, I saw the long shining sprays of the beautiful *Marinum*.

But how to get at it?

Mounting as high as I dared on a tiny ledge till hat and chin peered over the projecting rock, steadyng myself with one hand, with the other I hoisted up the bamboo, and began a sort of sky fishing, making desperate jerks to reach my object, when suddenly there boomed on my ear like a cannon, "Bless my soul, madam, you'll be killed! Hold on till I come." But who was "I"? Just rounding the cliff came a little boat, and in it a gentleman, a lady, and a sailor. Stout and ruddy against the blue sky showed the pair as I sighted them over the point. The "situation" was not exactly happy, but with a firm hold I was master of it. The party landed. The gentleman bowed, and asked leave to take my place; but even then we were but a few inches nearer the Fern. Then the sailor came, and, like Cæsar, saw and conquered. "Yes, yes," he said. "Sure she's high, but I'll get her. May I stand on your shoulder, sir?" In a moment the boatman was on the stranger's arm, clinging to a scrap of rock. A spring, and he was safe on a ledge, securing root after root of the desired treasure; and thus I became possessed of the first living specimen for a fernery that has been my pleasure for ten years.

The little party in the sea-cave gathered round the Fern, feeling we could hardly admire it enough, with its black shining stipes, its simply pinnate frond—not stiff, as in cul-

tivated specimens, but with a waving curve of dark bright green on which the light glinted—it's fructification (it was autumn), rich, full, and brown, traversing from either side of the mid-vein of the pinnule to the serrated outer edge.

After due examination, the sailor took a "cordial" from our pic-nic flask, jumped into his boat, and the party, so strangely brought together in pleasant fellowship in that lonely spot, parted for ever. I planted the roots in pots half full of drainage, and I have them now as green and beautiful as then. In looking at them I often wonder whether there still exists in another English home one of the trophies of this day, of which a gentleman says in a jolly voice, "That, my love, is the Fern I found the day I saved the lady's life in the Welsh cave;" and whether the rejoinder remains, "My dear, you were very foolish, and it was the sailor!"—*FILIX-FEMINA.*

ANNUALS AND BULBS FOR GARDEN DECORATION.

THE time is drawing near when there will be a blank in the flower garden from the removal or destruction of its summer occupants, unless prompt measures be taken to replace them by plants calculated to do away with the dreary aspect which the beds too frequently present in winter, spring, and early summer. The flower garden can be made interesting from the appearance of the Snowdrop to the blooming of the Rose; in winter, by a discriminate use of small or miniature evergreen shrubs; in autumn by the preparation of the beds for bulbs and other spring-flowering plants; in spring and early summer, really beautiful by means of a variety of plants.

It is high time to sow seed of the following annuals for flowering in the ensuing spring, and as the beds will not be ready for them for some time, it is advisable to sow rather thinly in a sheltered situation, and, if possible, on well-drained ground. If the soil is poor and light a dressing of leaf mould an inch thick, spread on the surface and neatly pointed-in, will benefit the plants. Prior to sowing tread the surface firm if the soil is at all light and sandy; but if tenacious in character treading will not be required. It is necessary to have the soil firm that the plants may make fibrous roots, so that they can be removed with a close ball. It is also certain that seedling plants withstand frost much better in a firm than in a loose soil, and they are there stronger and more dwarf. Having levelled the surface and sown the seeds thinly, but rather more thickly than in spring sowing, only just cover them with very fine soil. If all go on well they will be up in a few days, when a vigilant watch must be kept on the seedlings to prevent their destruction by slugs. A little soot sprinkled around them will do much to prevent the ravages of these; but the best plan is to search for them at night with a lantern, and the next best to dust a little quicklime over the plants at dusk in order to kill the depredators.

If the winter prove mild all will do well and be of sufficient size to transplant into their blooming quarters when the first mild weather occurs in March. Take them up with good balls and plant them thickly, consolidating the soil about their roots. Water copiously if dry weather ensue, and thin the plants if they stand too closely; but this will rarely be necessary, the difficulty being to obtain enough of them to cover the surface densely.

To provide against accidents and to fill up blanks, it is advisable to sow a quantity in pots and afford them the protection of a cold frame, admitting air freely on all occasions, and protecting only in severe weather, when a covering of mats will do much to keep off frost, and if the mats be left on until the plants are thawed the injury sustained will be much less. To preserve the roots the pots should be plunged to the rim in coal ashes. Those who have room may keep them on shelves near the glass in cool greenhouses, and if an early bloom is desired they may be potted in spring and allowed to flower in the greenhouse. They should be transplanted to their final quarters if wanted for flower-garden decoration by the beginning of April. Light loam and leaf mould in equal parts form the most suitable compost. The seeds should be sown from the middle of September to the beginning of October, that being the latest period. September is the most suitable month.

The following are the annuals that I have found really useful for the decoration of flower-beds in spring, and although all of them do not flower sufficiently early to allow of their being employed, yet the majority answer the purpose on an average of seasons:—

- Alyssum maritimum (Sweet Alyssum), flowers white. 6 inches.
- Calandrinia speciosa, pink. 1 foot.
- Campanula carpatica, blue. A perennial and not suitable for bedding, but valuable for borders; and so is Delphinium formosum, blue.
- Campanula Lorei, blue; and its variety, alba, white. 1 foot.
- Clarkia pulchella, Tom Thumb, rosy pink. 6 inches.
- C. pulchella, in variety, $\frac{1}{2}$ foot.
- C. pulchella, compacta. A smaller variety of the common kind. 9 inches.
- Cochlearia acaulis, lilac. 6 inches.
- Collinsia bartsiæfolia, purple; and Collinsia bartsiæflora alba, white. 1 foot.
- Delphinium cardiopetalon, blue. 1 foot.
- Erysimum Perofskianum, orange. $1\frac{1}{2}$ foot.
- Eschscholtzia californica, yellow. 9 inches to 1 foot.
- E. crocea, yellow; and E. crocea alba. 9 inches to 1 foot.
- Eucheridium grandiflorum, reddish purple. 1 foot.
- Eutoca viscosa, blue. 1 foot.
- Gilia nivalis, white. 9 inches.
- G. tricolor, tricoloured. Collectively a bad white or grey. 1 foot.
- Gesleria tenella, purple. 1 foot.
- Gypsophila muralis, pink. 6 inches. This is only half hardy. Sow in a frame.
- Iberis umbellata (Candytuft), in variety. 1 foot.
- Kauiussia ameloides, blue. 9 inches.
- Leptosiphon aureus, golden yellow or orange. 3 to 6 inches.
- L. laevis, yellow. 6 inches.
- L. densiflorus, purple. 9 inches to 1 foot.
- Linnæanthes Douglasii, yellow and white. 5 to 7 inches. This does better sown in autumn than in spring. The white variety is excellent.
- Lupinus nanus, blue; and its variety alba, white. 9 inches.
- Malcomia maritima, red; and its variety alba, white. 6 inches.
- Myosotis palustris azurea major, blue and yellow. 6 to 7 inches.
- Nemophila insignis, blue. 3 to 6 inches. This sown in autumn does much better than when sown in spring. It makes a charming bed.
- N. maculata, white, spotted purple. 6 inches.
- Enothera prostrata, yellow. 6 inches. Makes a good bed throughout the season.
- Saponaria calabrica, pink; and Saponaria calabrica alba, white; fine. 9 inches to 1 foot.
- Schizanthus Priesti, white. 1 foot.
- Silene pendula, rose; and S. pendula alba, white. 6 to 9 inches.
- Venus's Looking-glass (Campanula speculum), blue and white varieties. 6 inches.
- Veronica syriaca, blue and white. Makes rather a pretty edging.
- Viscaria oculata nana, pink; and its variety, alba, white. 1 to $1\frac{1}{2}$ foot.
- Whitavia grandiflora, purple. 1 foot.

In point of utility for flower garden decoration I can only accord annuals a secondary position, as they are uncertain in their time of flowering, and cannot be depended on to survive the winter, at the same time it would not be just to say that they are of little value, though it must be admitted that they are vastly inferior to early-flowering spring plants and bulbs. Of flowering plants for spring decoration I shall have something to say by-and-by.

BULBS FOR FLOWER GARDEN DECORATION.

For the most part all hardy bulbs are easy of cultivation, needing no particular soil or preparation beyond that required by hardy plants in general. Bulbs of all kinds, however, thrive best in soils that are free from stagnant water, and which are moderately rich and porous. No general rules can be laid down as to the successful cultivation of the whole; but some hints on that of each genus may be of service.

SNOWDROP.

Simplicity and modesty are the peculiar charms of this lovely flower. It will grow almost anywhere, but prefers a free open soil, particularly if containing decayed vegetable matter, such as that found in woods not too much encumbered by brushwood. It will also bear almost any amount of ill treatment, and it is not unusual to see it transplanted when in full flower, and be but little injured. Such treatment, however, cannot be recommended.

Ground intended to be planted with this bulb should be dug or loosened to a depth of from 9 inches to a foot, and if a little leaf mould can be spared to mix with it so much the better. Immediately after the foliage decays take up the roots and divide them, sorting out the large from the small bulbs, it being a good plan to have three sizes—large, medium, and small. The large bulbs will answer perfectly for the most conspicuous places in the flower garden; the medium-sized will do for mixed shrubbery borders in open spaces, either in front of evergreens or under the shade of deciduous trees; and the small may be planted in woods, by the sides of walks, and in parks, a clump here and there, which will add additional beauties to such places. When-

ever the Snowdrop is taken up it should be planted the same day. It is a native of Britain, and as such is not benefited by the drying process. It is only plants from warmer climates that are improved by drying, which promotes the ripening of the bulbs—a process which cannot be accomplished in our cold damp soil.

They may be planted as margins to borders in lines about 6 inches from the edging, drawing a drill with a hoe 3 inches deep, and placing the bulbs in this at an inch apart in a double row, allowing 3 inches between the rows, and in quincunx fashion, so that the first row may be $4\frac{1}{2}$ inches from the edging, pressing the root end into the earth, and then covering with soil to a depth of 3 inches. In the same manner they may be planted as margins to flower-beds; but if the lines are curved the distance between the rows should not be greater than that between the bulbs, or from 1 to $1\frac{1}{2}$ inch. Double rows are much more effective than single, and treble rows better still. The foliage will usually be sufficiently decayed to allow of the Snowdrops being planted at the time of preparing the beds and borders for their summer occupants. Snowdrops may remain in the same place for a number of years, annual removal doing the greatest possible injury to these bulbs, and all others from cool climates. If removed more frequently they should not be planted so deeply, from $1\frac{1}{2}$ to 2 inches being sufficient covering; but when left for years they annually get nearer the surface, and unless top-dressed will ultimately throw themselves out of the ground, for under cultivation they are deprived of the annual deposit of vegetable matter which in nature enables a plant to exist on the same spot for generations. I was particularly struck with this on planting several roots under trees, from the ground beneath which the leaves were annually removed, and others in a spot where leaves and herbage were allowed to remain. They were all planted at nearly the same depth, but at the end of seven years the bulbs in the former situation were level with the surface, whereas the others were no nearer it than when first planted. In planting, therefore, in dressed ground, it is not necessary to remove them oftener than once in seven years, unless they have increased to such an extent as to throw each other out of the earth or become irregular. The medium-sized and large bulbs are those best calculated for planting in clumps of twelve or more together, at from half an inch to an inch apart. The small, planted in woods, on hedge-banks, or any other suitable place, will in time gain strength and afford additional charms to such spots.

Dried bulbs should be planted if possible in September, and not later than October, in order to secure a good bloom. They may be planted close to the stone edgings of beds, and in all beds and borders, without infringing on the space allotted to Crocuses, Tulips, &c., and they do not interfere in the least with the summer planting of the beds or borders.

The single Snowdrop (*Galanthus nivalis*), is the most graceful, usually commencing to bloom in January—never, so far as I have seen, before that time; the double-flowered (*Galanthus nivalis flore pleno*), succeeds it. *Galanthus plicatus*, or the Crimean Snowdrop, is double the size of our common English species, and possesses the same exquisite purity of colour, flowers at the same time, and has broad leaves, and flower-stems 9 inches or a foot high. It is a welcome addition to our earliest spring flowers, and must find its way into every garden.

I must now advert to what I consider a valuable acquisition—namely, *Colchicum alpinum*, a very dwarf kind from the Swiss Alps, roots of which, imported last autumn, remained in bloom the whole of the winter, even during the frost. The flowers are of a pale rosy purple, several rising from one root. It is probable that its winter-blooming properties may be impaired by our more temperate climate; but should it retain them, it will be valuable as being one of the few flowers of midwinter.

WINTER ACONITE.

This is a charming early-blooming plant, rising to the height of about 6 inches, producing, when in a mass, a blaze of golden blossoms. It requires the same treatment as the Snowdrop, and should be in every garden. I once had charge of a garden where there was a tall screen of Lime and Elm trees, and a walk between them, and on each side was a yard of single Snowdrop, another of Winter Aconite

(*Eranthis hyemalis*), a third of double Snowdrop; and this walk, when the majestic arms of the trees were crusted with hoar frost, and there was just a sprinkling of snow to whiten the ground, had a splendid effect, especially when the sun shone. The Winter Aconite flowers in the months of January and February, and frequently in March.

CROCUS.

Neat, dwarf, compact in growth, the Crocus ranks as one of the most beautiful ornaments of the flower garden. Like the Snowdrop, it may be planted so near the margin of beds as not to interfere in any way with the other occupants. It is so varied in colour as to be charming in beds or borders, either in lines of one colour in ribbon borders, or in concentric rings in beds; and nothing can exceed the beauty of a border planted in clumps of one colour, or of several blended together, especially when associated with Hepaticas, and particularly the pink one.

Crocuses are usually planted in October, November, and December; but I should be guilty of misleading my readers were I to say that such is the most suitable time. It is ill treatment to dry Crocuses at all, for they are not improved by the process, nor, as I said before, is any bulb that will endure our climate, and become sufficiently ripened. To do the Crocus justice, it should not be removed more frequently than once in three years, and must then be planted the same day. They like a rich, open soil, not necessarily dry, but free from stagnant water. Planted in lines, they should be inserted to a depth of 2 or 3 inches, and at a like distance apart. In clumps of six or more they are very pleasing. The bulbs in this case need not be more than an inch apart. The Crocus does not grow under trees so well as either the Snowdrop or Winter Aconite, owing, I think, to its growth not being perfected before the shade of the trees deprives the foliage of light to a great extent. It should, therefore, have an open situation; but at the time of re-transplanting it is desirable to plant only the largest bulbs in the most prominent positions, reserving the smaller for places of less importance. The most suitable time to transplant Crocuses is immediately after the foliage decays.

I have no wish to depreciate imported Crocuses, for I find that they furnish larger blooms than those of English growth; and I wish to impress on the minds of all that finely as imported Crocuses flower the first year, they will, if not disturbed, improve in beauty, not for the next year only, but many succeeding seasons. Imported bulbs should be planted in their quarters as early in autumn as the places can be got ready for them.

The Crocus, after being grown in the same soil for a number of years, becomes weaker. To obviate this, a portion of the old soil should be removed, and its place supplied by a quantity of fresh rich soil. A dressing of rotten manure spread over bulbs early in autumn is not lost on the roots beneath, and such attentions should be more frequently given than they are.

Very fine beds may be formed by planting a double row of Mont Blanc, white, 6 inches from the edge; 6 inches from that again a double row of Prince Albert, blue; then at a like distance Dutch Crocus, yellow; a fourth of La Majestueuse, striped; a fifth of Othello, dark violet; and Giant Yellow in the centre. This will be splendid for a circular bed 7 feet across. For a border 6 feet wide we have the first row, 6 inches from the Box or other edging, a double one, white, Queen Victoria; the others being—2, Cloth of Gold, yellow; 3, General Garibaldi, purple; 4, Aletta Wilhelmina, white, flamed violet; 5, New Large Yellow; 6, Vulcan, deep purple. The second row is 1 foot from the first, and so on, early Tulips being planted between each. Again we have a border 12 feet wide, which is to be gay in early spring. Such will hold twenty-four rows, and we can have it first-rate by planting, beginning at the edge—1, Queen Victoria, white; 2, Captain Cook, purple; 3, Cloth of Gold, yellow; 4, Argus, violet, white margin; 5, David Rizzio, dark purple; 6, Sulphureus, brimstone yellow; 7, Mont Blanc, white; Prince Albert purple; 8, Large Yellow; 9, Cloth of Silver, white, purple stripes; 10, Ne Plus Ultra, blue, tipped with white; 11, Yellow Dutch; 12, Princess of Wales, dark purple; 13, Caroline Chisholm, white; 14, New Large Yellow; 15, Albion, blue, white and blue striped; 16, Van Speyk, feathered blue and white; 17, Saffron; 18, Lord Raglan, dark

blue; 19, Diana, white; 20, Cloth of Gold; 21, Lilacæus superbus, light violet, white margin; 22, Versicolor, white, with purplish veins; 23, Large Yellow; 24, Grande Vidette. Planted in this way, a border of Crocuses is not to be rivalled; and to a true lover of nature there is no finer sight on a bright spring day.

Now as Crocuses are only temporary, or destined to give place to other flowers at a more advanced period of the year, it becomes necessary to remove them with balls in the last week in May, planting them again in an open situation in the reserve garden, giving a good watering, but none afterwards. In autumn they may be retransplanted to the places previously occupied, at latest by the beginning of November. They will bear this treatment better than might be expected; but a system which I have adopted with more success, is to plant the Crocuses in double rows (I do not like single), the first 6 inches from the edge of the bed or border, and the next a foot from it, and so on, which leaves space between for planting early Tulips, and these come off in time for bedding plants to be put in their places, without disturbing the Crocuses. The Tulips look no worse for having a line of the loveliest foliage between the rows, but are improved; and thus we do justice to the Crocuses, and have a bloom from early spring until a late period, when they are replaced by other plants not more beautiful than their predecessors.

(To be continued.)

G. ABBEY.

TRITOMA UVARIA—GLADIOLUS.

FROM remarks made by gardeners who visited various places in the latter part of the past summer, coupled with what little observations I have been enabled to make myself, I should certainly think that very ornamental plant, Tritoma uvaria, has lost the high position it held in the last and preceding years. The expectation then formed of it was, that it would take a place amongst the tall bedding plants, or, perchance, a row of it would be found occupying a site where Dahlias, Sweet Peas, or the taller Tropaeolums had previously done duty; but, whether from the dry summer, or from some other cause not sufficiently understood or accounted for, the flowers of this plant in most places seem to have been few indeed up to the middle of September, and the condition of the plants such as to leave little hopes of their making much display this autumn. That this is in a great measure to be attributed to the dry weather I fully admit, but I am far from certain that such is the only cause, as in my own case the plants in spring seemed to be in anything but a promising condition; many of them had died during the winter, and I find on inquiry that other growers had in a like manner lost a great portion of their stock, and as this could not be from the lack of moisture at that season, some other reason must be assigned for the failure of this popular plant, which, whatever may be its merits, is certainly not an early bloomer.

It would, however, be premature to condemn it for not succeeding better in a dry season like the present, but its failing during the past winter can hardly be attributed to the same cause, especially as we are told that the plant is one of the hardiest we have. Be this, however, as it may, the Tritoma uvaria of 1864, seems to have lost the position it occupied in the preceding years, and the quantity of flowers is likely to be much less than we have had for several seasons.

I believe it is admitted that this Tritoma likes a damp situation, possibly the side of a brook or ditch, where the soil is open, or, perhaps, inclined to peaty sand. A stiff clayey soil is too likely to produce slugs, which prey upon this plant, and I expect that last autumn, which was unusually mild, favoured these destructive vermin, and to their voracious appetites I fear some of our winter losses are to be attributed. One thing at all events is certain, the plants did disappear, and as severe weather did not set in until the first week in January, these marauders may be fairly charged with a part of the blame; but if, on the other hand, this plant has suffered from any of the other causes by which other classes of plants are affected, some further inquiry ought to be made into the matter. Perhaps other growers who have been more fortunate will kindly record the circumstances to which their success is attribut-

able, and any other particulars relating to this highly popular plant, so that where local circumstances will permit of the mode of cultivation being varied, we may look for success with somewhat more of certainty than we can at present.

While on this subject, I may mention that at most of the places to which I have been this summer, the Gladiolus has done well, and those we have here have flowered abundantly and strongly, and retained a better foliage than usual. Even in the dry weather of August they seemed not to lack any of the freshness which was so wofully absent in other things, and from this we may infer that the Gladiolus hardly requires hand-watering, nor yet a dripping summer to do well, but simply wants bright sunny weather. Of course, it need hardly be stated that this hastens the decay of the bloom, as well as its production, and that those who want a prolonged display must, therefore, adopt some shading process. The condition of the plants, however, in the present autumn, and their past success, augur favourably for another year; let us hope that the Tritoma may also raise its head in a more prominent manner next season than it has done this, and that a like failure may not occur again. If any one who, by a different mode of culture, has succeeded this season would record his practice in THE JOURNAL OF HORTICULTURE, he would confer a great benefit on others, who, like myself, are far from satisfied with the result of this year's growth.—J. ROSSON.

LEAN-TO ORCHARD-HOUSES.

1. WHAT do you consider the best height for the back and front of a lean-to orchard-house, so that a narrow path might be made round the front for a man to squeeze along in pruning?

2. Do you think it a good plan to raise the back border 2 feet?

3. Will 14 feet wide hold four rows of trees when matured, with a two-feet path in the middle, and one of 18 inches in front?—A. Q.

[It is impossible to gain every advantage by any one mode of building a house. The low-fronted houses, as Mr. Rivers's lean-to's, are no doubt the cheapest. Our orchard-houses this season have been pictures of health and fertility. The garden-wall existed previously, it is 11 feet in height, width of house 11 feet, height in front 3½ to 3¾ feet, according to the slope of the ground. There are trees against the back wall, and 5 feet from it a row of trees in pots, and a second and third row near the front, just leaving enough of room for a man to get along stooping. The whole of the back of the house as well as the front is supplied with dwarf temporary plants in the spring, for keeping and hardening-off. The trees used may be kept much the same size by pruning, or if allowed to grow larger, a less number of trees will do. If heavily cropped, some will be exhausted prematurely. Our pathway now is latticed wood 18 inches wide. With a house at all moderate in height, there is no occasion for sinking the pathway. That was done to obtain headway in a low house and thus secure economy.

In your fourteen-feet wide house if no walls now exist, and West Houghton is far enough south, you might make a span-roofed house easiest—say 5 feet at sides and 10 feet at apex, the half of the 5 feet glass, and a walk down the middle, with a bed for two rows of trees on each side. If you resolve on a wall and a lean-to, then we would have the back wall at least 12 feet in height, and the front from 4 to 6 feet, the latter height if you want a comfortable pathway in front, the former if you are satisfied to pass along as you can. Then for internal arrangement we would advise you to have trees planted out against the back wall, and no other trees in the house for from 5 to 5½ feet from the wall, and these should not be allowed to be above 5 or 5½ feet in height. This opening at the back of 5½ feet or so would be the main passage, and thus you might have three rows of trees in front, either in pots or planted out, and root-pruned as necessary. By this mode you could have Peaches and Nectarines against the back wall, and Cherries, Plums, &c., of the best sorts in front. Bear in mind what has frequently been referred to in "Doings of Last Week"—the watering that will be required for trees in pots. The labour in this respect would be lessened if the trees were planted out; but then they are kept small with more difficulty.

The plan involving least labour in such a house would be to plant against the back wall, and to plant also in front, and train to a trellis some 15 inches from the glass, the trellis to be rounded at 5½ feet from the back wall, so that the sun's rays could reach the bottom of the wall. The trellis at the highest should not, therefore, be more than 6 feet from the ground.

By not planting trees against the back wall and having your main path in the centre, you will have beds on either side that will each hold two rows of dwarf plants. In such a case we would advise the back border being raised 18 or 24 inches, as that would secure more sun light to the back bed. For the sake of neatness, however, one side of the pathway at least would need to be held up with bricks or something of that kind. With such a height as we have spoken of, the back border might be 15 inches higher at the back, slope gradually to the front, and thus a sunk path be avoided, and the expense of keeping up the sides. In our lean-to's the ground at back is about 15 inches higher than in front, and the narrow wooden trellis is on the level. Formerly we had a nice gravel path within 2 feet of the back wall; but we could not keep it moist enough, and greatly prefer the narrow wooden path through which we can pour water at pleasure. Did we wish to try pots, as you are resolved to do, in such a fourteen-feet-wide house we would plant out against the back wall and have three rows of trees in pots in front, the back row not nearer than 5 feet from the back wall, nor above 5 or 5½ feet in height. We would only leave from 18 inches to 2 feet for passing along in front, and unless the front were 5 or 6 feet in height, we would not seek a regular pathway there.

We think these remarks will embrace most of your questions. If you do not plant out against the back wall the border will be all the better for being raised there, and you will have ample room at first for four rows of trees. By keeping to the bush form and having the main pathway in the middle, if ever you wish to plant out the best specimens, one row in each bed will be enough, and you could put a pot plunged in any open space so that no room should be lost. In spring, autumn, and winter such a house will be useful for many things besides the fruit trees.—R. F.]

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 27TH.

FLORAL COMMITTEE.—At the meeting held this day there was an extensive display of seedling Dahlias, but few were considered worthy of certificates.

Mr. C. J. Perry, Castle Bromwich, had *Ne Plus Ultra*, large, and of fine form, and quite distinct in colour, pink veined with buff yellow. This well deserved the first-class certificate which was awarded to it. *Startler*, dark maroon, with pale blush tips, was also a pretty flower. Mr. Turner, Slough, again exhibited his fine, deep golden yellow seedling *Leah*, which has been noticed in previous reports as being a first-class flower, and on this occasion it fully maintained the character which has been given of it; also, *Rosetta*, rosy crimson, with a magenta tinge, a very bright colour. Mr. Turner likewise sent a collection of the sorts sent out by him, comprising large and fine blooms of *Lord Palmerston*, *Lord Derby*, *Criterion*, *Charlotte Dorling*, *Princess of Prussia*, *Chairman*, *Cygnets*, *Lord Clyde*, *Leah*, and others. For this he received a special certificate, and a similar award was made to him for five boxes of *Roses*; among the finest blooms were *Senateur Vaisse*, *François Lacharme*, *Pierre Notting*, *Vainqueur de Goliath*, *Olivier Delhomme*, *President*, *Beauty of Waltham*, and *Souvenir de Malmaison*. *Gloire de Dijon*, with which alone one box was filled, was in splendid condition. A plant of *Lilium auratum* bearing two of its immense blooms was also shown by the same exhibitor. A box of *Roses* in very good condition was likewise contributed by Messrs. Paul & Son.

Mr. Rawlings, Bethnal Green, had a second-class certificate for *Dahlia Purple King*, a large and showy kind, lilac purple with a magenta tinge; Mr. Sladden, *Queen Victoria*, *Mrs. Sladden*, *Sparkler*, *Exquisite*, and others, which were shown at the meeting of the 13th of September, were again exhibited, but the Committee did not think them worthy of an award.

Mr. Legge, Edmonton, sent Black Doctor, with fine large very dark blooms; also, Excellent, Ellen, Mr. Golding, Dauntless, Glory, and others, most of which had been previously shown, but not thought of sufficient merit. Mr. Knight, Battle, had Albert Edward, large blooms, carnation-striped and flaked on a buff yellow ground; Mr. Burgess, Chelsea, President Davis, reddish buff; and Mr. Hopkins, Brunette, apricot, very deeply laced with dark crimson. The following were shown by other exhibitors, but received no award—viz., Earl Radnor, Mrs. Brunton, Lord Clifden, Boule de Feu, Fanny Sturt, Queen of the Vale, Chrome, and Beauty.

From Mr. Standish, Ascot, came two very fine seedling Gladioli, for both of which first-class certificates were given. They were—Our Little Lucy, bright magenta rose veined with white, and having a purple feather in the throat, very distinct and beautiful; and Miss Mowbray Morris, large flower, flesh, with splashes of rose, and purple feather, a very fine variety. Skimmia oblate, also from Mr. Standish, was likewise awarded a first-class certificate. It is very ornamental both in berries and foliage, the former being oblate and bright red, the latter of a uniform light green, and it is stated that it stands sun well.

Mr. Veitch, Chelsea, sent a magnificent basket of Odon-toglossum grande, the flowers $5\frac{1}{2}$ inches across, the plants in which had been treated on the cool system, never having been afforded fire heat since last winter. For this a well-merited special certificate was given. Cattleya exoniensis, one of the hybrids raised in the Exeter nursery by Mr. Dominy, the parents being Cattleya Mossiae and crispa superba, had a first-class certificate. The flowers are large and showy, the lip being deep purplish crimson, orange veined with purple at the base, and the petals and sepals of a delicate lilac blush. Odontoglossum Uro-Skinneri, was also contributed by Mr. Veitch.

Mr. Watson, gardener, to C. Leach, Esq., Clapham Park, had a first-class certificate for Nerine coruscans major, a Cape bulb with fine, compact heads of orange scarlet flowers, the stamens, of the same colour, standing out conspicuously above the divisions of the flower. He likewise exhibited species of Nerine and Brunsvigia of no remarkable beauty, and a showy Haemanthus, with orange anthers and scarlet filaments.

Mr. Smith, Hornsey Road, received a second-class certificate for Petunia Fame, with crimson purple and white flowers, a pretty variety. Mr. Barker, nurseryman, Godalming, had a first-class certificate for Asplenium resectum, a very pretty stove Fern from the Island of Ascension. From the same exhibitor came also Pteris flabellata ascensionis, Asplenium erectum proliferum, in which the fronds are proliferous towards their extremities, Psilotum triquetrum, three pretty varieties of Mimulus, and twenty-four kinds of Tropaeolum, among which were several brilliant in colour, and others peculiar in their markings.

Mr. Parsons, Welwyn, contributed Achimenes Stella, rich velvety crimson purple, a fine variety, for which a second-class certificate was awarded; Mr. Batley, Rugby, a stand of seedling Verbenas; and Mr. Thompson, Ipswich, Callirrhoe involucrata, crimson purple, with white base, which was commended as likely to prove a useful border annual. Lastly, from Mr. Bull, came Dendrobium aduncum, with small but pretty white flowers, with a faint blush of lilac; Cattleya bicolor major, with a rosy purple lip, and olive sepals; Adiantum prionophyllum, Alocasia longiloba zebrina, the leaves metallic green, and the leafstalks with zebra markings; and Fuchsia The Giant, with very large double flowers, the corolla blue violet, and the sepals scarlet, but in the specimen seen not reflexing well.

FRUIT COMMITTEE.—F. J. Graham, Esq., in the chair. A scarlet-fleshed Melon of good size weighing about 3 lbs., was received from Mr. John Murdoch, gardener to H. Allsopp, Esq., Hindle Hall, Worcester. The flesh was very tender and melting, and the skin thin, and the flavour was remarkably good, so much so, that the Committee awarded the fruit a first-class certificate. Mr. Henderson, of Trent-ham, sent a dish of very handsome Peaches, of the variety known as Gregory's Late. This Mr. Henderson considers the best of all the late Peaches, both as regards flavour and lateness, and his opinion was confirmed by the Committee, who unanimously considered it a variety worthy of

general cultivation. Mr. Myers, of Brentford, also exhibited a fruit of the same variety. Mr. Graham, of Cran-ford, exhibited fruit of his Muscat Muscadine Grape, which was delicious in flavour, differing entirely from that of Chasselas Musqué, it is more brisk, and has a sort of orange flower flavour mixed with that of the Muscat. This was produced in a house without any fire heat. From the garden at Chiswick there were two varieties of Frontignans, Muscat Regnier, and Chasselas Musqué de Nantes, both very similar, and neither calling for special mention. Mr. John Richardson, gardener to Joseph Pease, Esq., Southend, Darlington, sent splendid bunches of Golden Hamburg, and Foster's White Seedling, but unfortunately they were so smashed in the box through being badly packed, that their beauty and flavour were destroyed.

MR. WILLIAM PAUL'S NURSERIES, WALTHAM CROSS.

IT is now upwards of two years since we paid more than a passing visit to these nurseries, though often intending to go over them in a deliberate manner; but want of time, and the very knowledge that there is something there to interest at all seasons, were the cause of that intention not being carried into effect till the other day. As a walk leads directly from the platform of the Waltham Station to the nurseries we availed ourselves of that mode of access, and passing beside large quarters of fruit trees, Conifers, and ornamental shrubs, and then along a broad grass walk with beds of evergreens on each side, we reached the office, where we were fortunate enough to find Mr. Paul, who kindly offered to show us round. In leaving it we passed through the shop, which, as might be expected in the height of the bulb season, was full of Hyacinths, early Tulips, Crocuses, Narcissus, &c.; and on remarking on the size and weight of the bulbs, Mr. Paul informed us that they were the largest and heaviest which he had ever imported.

Being anxious to again look at the splendid new Geraniums which Mr. Paul is about to send out, we visited the houses first. Of these several new ones have been erected during the last two years, and one is now being completed. They are all span-roofed, about 50 feet in length, and from 18 to 20 feet in width, and the whole are efficiently heated by means of two boilers, one being a modification of the saddle-form, and the other one of Monro's cannon boilers, with the performance of which Mr. Paul expressed himself perfectly satisfied. These houses, though alike in their general appearance and of the most simple construction, are admirably adapted to the purposes for which they are severally intended, and might be studied with advantage by those who seek to erect glass structures combining efficiency and durability with economy.

The first house we entered was filled with Tea Roses, planted out in beds in the middle and at the sides, and trained up the pillars and over the roof. Notwithstanding the dryness of the season, which has affected plants under glass as well as those out of doors, in consequence of its being impossible to preserve at all times the requisite degree of humidity in the atmosphere, Noisette Lamarque and some other Roses in this house have made extraordinary growths, varying from 5 to 7 feet in length. Gloire de Dijon, planted in the central bed, and grown on its own roots, is trained to a single stem $7\frac{1}{2}$ feet high, the growth of but one year; and as a further example of the rapidity with which this variety grows, Mr. Paul informed us that he knew an instance in which it had in one year gone up 14 feet of the front of a cottage and then run 7 feet along the roof, making a growth of altogether 21 feet. Were it not that almost all the ripe shoots have to be cut for buds, this house would be a magnificent sight, but as it is it contains many glorious blooms, scenting the air with their delicious perfume. Of the numerous varieties planted here, Celine Forestier is the freest and best yellow climber, and the blooms are well set off by the fine mass of green foliage which it produces. That superb variety, Gloire de Dijon, was also in fine condition; indeed, if properly managed it is seldom seen otherwise. These two with Belle de Bordeaux, pink, resembling Gloire de Dijon in habit, are the best three for covering a house. Isabella Gray and Jane Hardy are also fine climbers, with beau-

tiful deep yellow flowers, but unfortunately they will not expand their blooms unless planted in a dry soil and warm situation; on the other hand, Homer, delicate in colour, tinted blush with a salmon centre, is at once vigorous and one of the hardiest of the Tea-scented Roses; and Nina, with large and very pure blush flowers, is a lovely hardy kind for planting out of doors, but not a climber. Of others we observed Ophirie, nankeen and copper, a good climber for a house coloured white, against which the lighter Roses do not look well, especially if the foliage is not vigorous and plentiful; America, creamy white, large and fine, excellent for a south wall in a warm situation; Nipheta, lemon white, large and very beautiful; Eugène Desgaches, rose, very large and sweet; Due de Magenta, salmon, large, and cupped; Nisida, rose and yellow, exceedingly sweet, and a profuse and continuous bloomer; Marquise de Foucault, fawn, salmon at the centre, delightfully fragrant; Solfaterre; and Julie Mansais, lemon white. Another house, distinguished as No. 5, was likewise filled with a fine collection of Tea Roses in pots.

In the next house we entered was a collection of fine healthy Vines for fruiting and planting out, amounting to sixty or seventy sorts, and with the wood rapidly becoming well ripened. Passing from this we came to a second viney, into which Mr. Paul introduced forty-one varieties, both new and old, in order to ascertain the comparative length of time required for ripening. They were all grown in pots, and subjected to cool greenhouse treatment; and many of them were bearing fine bunches, though some of the finest which were exhibited at the Crystal Palace Show had suffered considerably in consequence. Among them were Calabrian Raisin, a good late white Grape, which answers well for pot culture; and Muscat Noir de Jura, an excellent late black kind, which possesses the additional recommendation of being ornamental by its foliage, which changes in autumn to yellow and red. Chaptal, bearing eight fine bunches, fully justified its character for productiveness, and as being well adapted for pot culture; Foster's White Seedling was likewise bearing good bunches, as well as Chasselas de Falloux, the berries of which when ripe have a reddish tinge. This is a variety of acknowledged merit for pot culture, being remarkably productive. Black Monukka, though by no means first-rate, was producing good bunches and has the property of being stoneless. Some very large bunches of this kind were produced in the conservatory at Chiswick two years ago. Of new Grapes General de la Marmora, white, was bearing large bunches and abundantly; Chasselas Bulberry was very thin-skinned and transparent; and so, too, was Almeria. The others were Chavoush, Ingram's Prolific Muscat, and Perle Impériale, a fine-looking berry of a pale amber colour. Chasselas Vibert, though better known, deserves mention on account of its abundant bearing, large berries, and suitability for pot culture.

The next house was filled with a stock of Vines ready for fruiting in pots; and we observed that the wood was short-jointed, hard, and solid; with large well-developed eyes, such as give the promise of starting vigorously.

We now came to a house in which were many of the best of Beaton's Geraniums, and though the requirements of propagation to meet the great demand which will unquestionably arise for these had made great havoc among the shoots, there was still enough to show what valuable acquisitions they are. Amy Hogg is decidedly the finest, being entirely new in colour—a bright purplish rose; producing enormous trusses, and having the habit of Cybister, it will doubtless be planted by the thousand when known, and no one can fail to admire it. Indian Yellow, scarlet suffused with yellow, is another first-rate kind, which cannot fail to become a general favourite. Scarlet Gem, with large orange scarlet flowers and dark horseshoe leaf, will be very useful on account of its colour and dwarf almost creeping habit. Black Dwarf, crimson scarlet, is also of dwarf habit; and the trusses, which are freely produced, are very compact. Glowworm we did not see in flower, but from what we have seen of it on former occasions we can affirm it to be a sort of great promise; the colour of the top petals is a brilliant scarlet, that of the lower ones carmine with a magenta tinge. Orange Nosegay, bright orange, and Donald Beaton, orange scarlet, are both very desirable free-growing kinds; and Mrs. Wm. Paul, with broad finely formed petals of a

delicate peach, if sufficiently free-flowering, will be a great acquisition.

The above are only a few of the best of Mr. Beaton's seedlings, for these amount altogether to about 4000, many of them presenting new shades of scarlet tinged either with orange or magenta; but Mr. Paul is thinning them out as they come in flower, and discarding the least promising and distinct. It is not, perhaps, of much utility to attempt describing plants before they are named, but we may mention a variety with broad silvery edges and pink flowers; another with leaves of a similar character, but not so broadly edged with white, and having magenta flowers; a salmon red, shaded with orange towards the eye; an intense scarlet with broader petals than Stella; and a magenta with a very distinct orange blotch at the base of the top petals, but the flowers as seen were rather small.

Passing by another house filled with Vines, we reached an orchard-house, in which were Peaches, Nectarines, and Apricots planted out, Figs in pots, &c.; but the crop had been gathered except from Late Admirable Peach, which was bearing good-sized fruit in abundance, and Stanwick Nectarine, which appears to succeed much better in orchard-houses than out of doors; the tendency of the fruit to crack is, however, a great drawback to this otherwise excellent variety.

This house is not heated at any period of the year, and except in being provided with wooden shutters sliding in grooves at the sides, it does not differ in its construction from the other structures. The object of having wooden shutters instead of glass at the sides is to economise heat, which in severe weather would be rapidly carried off from the glass; and by shutting up early with sun heat the thermometer is never less than 5° higher in the morning than it is out of doors, and the blossom is never injured by the spring frosts, which render the crops from unprotected trees so uncertain. The soil used is strong turf loam and nothing else; and to prevent the trees becoming over-vigorous, as well as to promote fruitfulness, they are taken up every second year in autumn, and the crop of the following season is never diminished but rather increased by the removal.

Adjoining the orchard-house a new span-roof is in course of erection for pot Roses. The dimensions are nearly the same as in the case of the other structures, but both roof and sides are to be fixed. Ample ventilation, however, is provided at top by hinged sashes of the same length as the rafter, and which open upwards; whilst air is admitted at the sides by openings in the wall, closed by wooden shutters placed in the interval between every pair of top ventilators, so as to prevent strong draughts.

Several propagating-pits were filled with Vines, Roses, new Geraniums of all kinds, and multitudes of Conifers, such as Thuja aurea, Pinus Lambertiana, Picea Nordmanniana and nobilis, Juniperus chinensis, &c., the number of Conifers raised each season being altogether about 20,000. In one pit were 3000 dwarf Roses, and in another a fine lot of seedling Picea nobilis and several Japanese plants, as Retinosporas, Sciadopitys, Thujopsis dolabrata, &c. One of these, Raphiolepis ovata, now in flower, will, if sufficiently hardy for our climate, prove a great acquisition, the foliage being of the deepest green and of thick leathery substance. As an edging plant, Euonymus radicans variegata promises to be very useful, having the leaves variegated with pure white, and being, moreover, perfectly hardy; and another of the same genus, E. japonicus aureo-variegatus, with dark green leaves and golden variegation, makes a beautiful table plant. It has been shown several times during the last two seasons, and wherever seen has been favourably noticed. A still more valuable acquisition is the new Japanese Osmanthus ilicifolius, which closely resembles the Holly in appearance, forming an admirable substitute for it, and, as far as observations have hitherto gone, of more rapid growth under ordinary treatment. There is besides a variegated form, which may be used to replace the variegated Holly.

We noticed in some of the propagating-pits an excellent and extremely simple contrivance substituted for hinges to the propagating-frames inside the pits. It merely consists of an iron strap attached to the woodwork of the back of the sash, bent so as to hook over a slightly curved piece of iron fixed edgewise on the frame, thus—

This never goes out of order, and the sash can be lifted off whenever it may be necessary to do so.

Passing by other pits where there were thousands of seedling Hollyhocks and dwarf Roses, and merely glancing at two tiffany-houses, which are invaluable for shade and coolness in summer, we came to the nursery quarters, where we had intended to make a lengthened stay, but from want of time were compelled to content ourselves with little more than a run through. This was the more to be regretted, as Mr. Paul has bestowed much attention on trees and shrubs and their adaptation to particular soils and positions so as to produce effect in planting. Among Yews were a lot of well-grown and compact plants of the Golden, and a kind intermediate between the Irish and the common, with a fine pyramidal form and very dark almost black foliage. There were, besides, interesting collections of English Hollies, Ivies, and quantities of choice Conifers—as *Thuya gigantea*, *plicata*, and *Lobbi*, *Thujopsis*, *Wellingtonias*, *Cupressus Lawsoniana*, *Piceas Nordmanniana*, *nobilis*, and *pinsapo*, various Cedars, &c.; in addition to quarters of Roses, altogether five or six acres in extent, containing multitudes of standard Roses, where *Gloire de Dijon* and Mrs. *Bosanquet* were blooming finely, while Dr. *Lindley* was remarkable for its extraordinary vigour and the size of the leaves, many of them $3\frac{1}{2}$ inches in length. The last-named, although not actually in bloom, was covered with flower-buds. A bed of the variegated *Rhododendron ponticum* was very conspicuous by its well-marked yellow variegated foliage; and the variegated *Acer negundo* was another invaluable plant for lighting up shrubberies and relieving the monotony of green which is so often complained of.

In the fruit-tree quarters, besides an extensive general stock, were large quantities of pyramid Pear trees of the best varieties, and what was alone worth a journey to Waltham to see, dwarf Apple trees on the Paradise stock, which though not more than 2 feet in height were bearing a most extraordinary crop, the fruits in many instances touching each other on the bearing-shoots. Several of these dwarfs had as many as thirty-seven Apples on them, not small but good medium-sized fruit, and where the variety was naturally large the fruit were so likewise, though not so numerous. These dwarf bush Apple trees were only $2\frac{1}{2}$ years from the graft, and were planted in rows $2\frac{1}{2}$ feet apart, and at not more than 18 inches from each other in the row. Assuming, however, that each tree were allowed 5 square feet of ground, an acre would hold 8712 bush Apple trees, and if these only bore fifteen fruit a-piece, the produce would be 130,680 fruit, or say 725 bushels, the value of which on the ground would be upwards of £100. Where bulk of produce for sale is the object, it may not be desirable to confine the trees to the same dimensions and space allowed them in the nursery-rows, but from what has been stated it is evident that a very large produce can be obtained from a small area, and that in all probability such trees would prove remunerative if planted on an extensive scale, whilst for small gardens they must be invaluable. There are many persons who could have at most but half a dozen standard trees, and many more who have only room for one, and tastes differ, varieties do not all ripen at the same season, most fruits that are good for the dessert are not fit for the kitchen; but by planting these dwarfs a long succession and diversity of flavour and appearance can be secured.

There is then something to be seen, something to be learnt, at Waltham Cross at this season as at others.

AMERICAN GRAPE-GROWERS.

A new beginner in Grape-growing must "keep cool:" as in all divisions of the sons of men the newest converts are the most unreasonable zealots,—he will find among Grape-growers those who give him the most trouble are they who have had the least experience. In one of our last year's volumes, our correspondent "Phineas Chewce"—vinous juice, we presume, changed to vinegar—happily hits off this peculiarity of the neophyte, by supposing him to recommend not only planting a cat at the roots of the Grapes he would have muskcat, but it must also be planted with its "tail to the north pole." The house must be of such a shape, such a size, such an angle, and such an aspect. None other will do at all. The plants must be set so, trained so, pinched so,

and pruned so; and so and so must be the hourly attention, daily practice, and yearly rule. The crop of your cold viney will give you the "cold shoulder," unless you heat it; and it will put on airs, unless you air it every day. So the story goes.

"The first thing hi does when hi goes hinto my viney hof ha hevening," once said a good gardener to us, "hi pulls hoff my hair." But "I should pull off my hair if I did," replies an equally good one; "I lower my sash, or open my ventilators in April, and let the air stay on all the year."

It is the fault of novices that they cannot distinguish between essentials and non-essentials. All these minute matters are well enough if you want superior Grapes; but good Grapes and plenty of them can be had easily and cheaply; and no matter how small a garden lot may be, one of the first improvements, after laying out the garden proper, we should recommend to be a cold grapyery.—(*American Gardener's Monthly*.)

CULTIVATION OF THE MELON.

(Continued from page 194.)

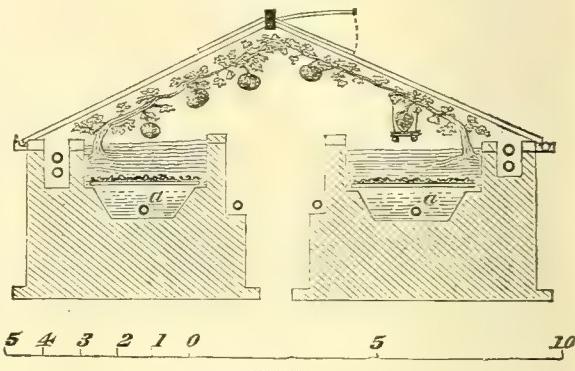

Fig. 12.

Fig. 12 is a span-roofed house, with a path in the centre and two beds on each side. The house is heated by six four-inch hot-water pipes, two just by the side walls within the house all round, and one on both sides of the path. Bottom heat is communicated by two hot-water pipes, one under each of the beds, in the first instance to a tank, *a*, *a*. The tanks are covered with slates, and on them a foot of compost is placed for the roots to run in. The plants are trained to a trellis. The ends of the house should be respectively north and south. A house of this description is admirably adapted for producing early Melons and Cucumbers.

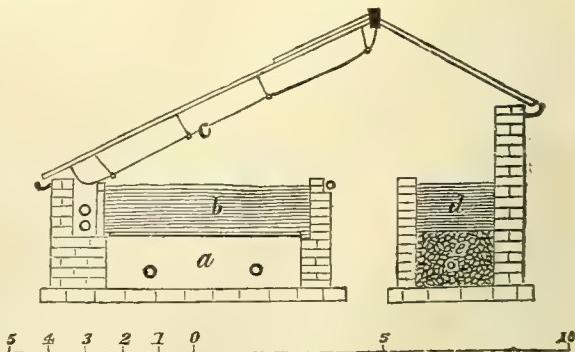

Fig. 13.

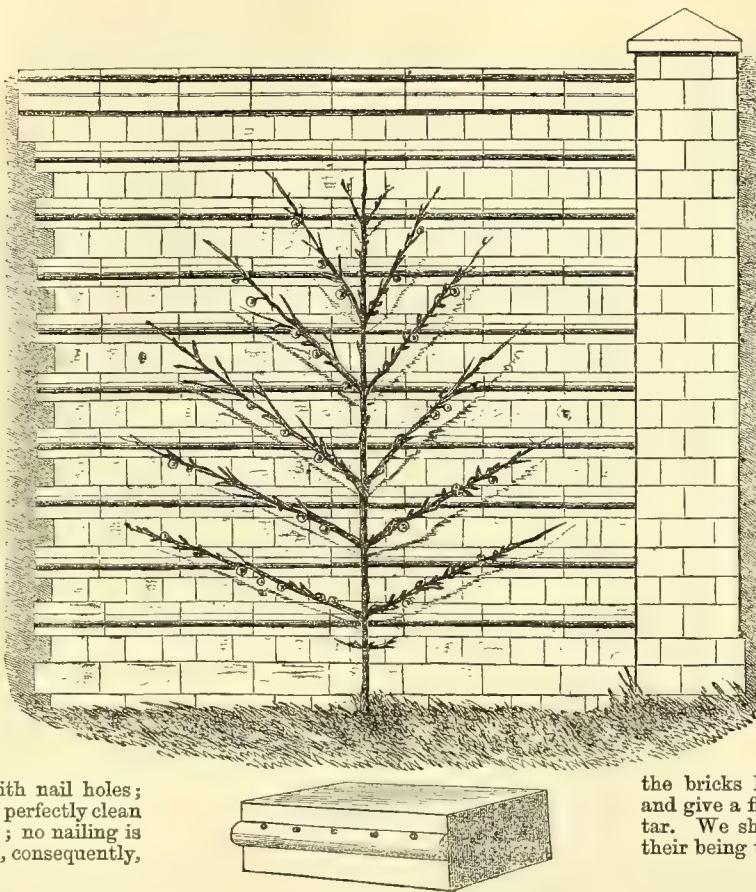

Fig. 13. This is simply a house with a half-span-roof. Bottom heat is supplied by two four-inch hot-water pipes to a chamber, *a*, and top heat by two pipes in front, and one to the left of the path in the centre of the house. *b*, is a bed of soil. There is a trellis at *c*, and a bed at back, *d*, which is very useful for plants, yet of no value for Melons. Bottom heat is furnished to it by a hot-water pipe, *e*, covered with rubble.—G. ABBEY.

(To be continued.)

FOXLEY'S PATENT CORRUGATED BRICKS FOR GARDEN WALLS.

ON the centre of the face of each brick is a stout bead projecting half an inch from its surface; this being pierced with holes at intervals of about 2 inches, serves by means of bast, string, or wire, to tie in the branches of trees.

Every gardener knows that walls against which fruit trees have been trained for a long series of years become much defaced by nail holes, and that repointing becomes necessary, not only to allow of fresh nails being driven in, but to prevent insects lurking in the crevices; but walls erected with these bricks have an ornamental appearance, and never get defaced with nail holes; the trees may be kept perfectly clean and free from insects; no nailing is required, and there is, consequently,

no danger of bruising the branches; and no extra fittings of iron, copper, or wood trellis are needed.

The bricks are made of the ordinary size, and, therefore, can be used in connection with common bricks. They are made either with a horizontal or vertical rib, but the horizontal is considered the best for general use. One thousand corrugated bricks are required to 3500 common bricks.

The smaller engraving below represents a single brick, showing the mode in which the projecting rib is perforated. The three holes at the end of the brick are only to make the bricks lighter, burn sounder, and give a firmer hold of the mortar. We shall be glad to hear of their being tried on a large scale.

NOTES ON FLOWER GARDENING IN 1864.

WHAT changes are yearly taking place in our flower gardens! For example, glance over a few of the many plants which have been brought forward within the last eight or ten years as flower garden plants. Along with many others I am gradually using fewer Verbenas, and only six or eight years ago we used them to more than double the extent we now do. I have repeatedly stated most of the objections to the Verbena being extensively used. First, the rambling habit which many Verbenas have prevents their being used in ribbons, or even very often in beds, with only a margin of some other colour; secondly, there is their liability to mildew in dull or rainy weather, and while such weather lasts they often refusing to flower satisfactorily; and, thirdly, two or three of our most choice sorts have this season been much affected with rust. This may, perhaps, have arisen as much from the very dry and hot atmosphere overhead as from dryness at the root. We managed to keep their roots in a tolerable state as regards moisture by watering, at least giving sufficient for them to have grown much better, and no doubt they would have done so, had not the atmosphere been always so very hot and dry. The rust almost killed several sorts of our Verbenas before the rain came.

As respects this rust upon some of our Verbenas, I cannot satisfy myself, but very probably they had been to a certain extent attacked by some sort of fly, which by puncturing the leaves had rendered them less able to battle against the hot weather.

I am pleased to say that my former favourite has again come off victorious. Purple King has stood under all conditions the best; all through the hot weather it was in

splendid bloom. Blue Bonnet, Array, Mrs. Holford, Robinson's Defiance, Géant des Batailles, Miss Hamilton Nisbet, and one or two other "selfs" we may still retain. However, none but selfs of good, distinct colours prove telling and effective. We have in one or two parts of our grounds to do battle against large Oak trees, and this year they have done so much injury that I shall keep as much as possible away from them in all future arrangements.

I am glad to say my favourites for the flower garden, the Geraniums, required less attention than almost anything else; and except in two places, where they were directly under the shade of an Oak tree, they have all grown and done well. Some sorts have yielded an immense quantity of bloom. Tom Thumb outdid itself with me this year in the amount of bloom which it produced. Stella Nosegay has commanded universal admiration from all who feel an interest in the flower garden. Brilliant has been indeed brilliant, especially during the hot weather; Baron Hugel was quite a mass of bloom; Christine has done well, and I might go very nearly over the names of all we have, and give a good report of all.

We grow about half a dozen sorts of Calceolarias, all good when used for the purposes for which they are best adapted. Some are good for ribbons when planted in the second row from the back; others to form the second row from the front. Next to the front row I use Aurea floribunda, and one that is not of quite so deep a yellow, but rather more dwarf, having the foliage not quite so stiff and erect, nor so much serrated. I am not able to give you its name, it is a very good dwarf. We use as a tall-growing one in certain cases, Polypheus, and as a yellow, Latifolia. Prince of

Orange has bloomed very abundantly, and when planted beside Flower of the Day Geranium, or any other light-foliaged kind, it tells well.

Some years ago I thought of dispensing with Petunias altogether in the flower gardens. However, these few seasons past I have made more use of them, and in some cases they tell well, and flower all the season. This is of itself a very great advantage. We have a bed of Scarlet Nosegay Geranium, encircled by a ring 18 inches wide of a small-flowered Petunia. The Petunia is kept pretty close down by the use of long hooked sticks. On the outside, next the grass, is a row of *Sedum carneum variegatum*, which produces a good effect. We use a small white Petunia in our panel border, white being a colour we are somewhat deficient in. We keep the white in this panel border pegged down in the same way as I have just stated. We plant it in squares of 10 or 12 feet, all the squares being divided by a band of yellow *Calceolaria*, and each square is made as much different from the others as the means will allow. A bed or square of white Petunias tells well planted between a panel of Tom Thumb and another of Scarlet Nosegay.

Has any one observed the singular inclination which the little *Sedum carneum variegatum* has, at least here in the Isle of Wight, to grow in its recumbent form more or less towards the sun? We have it in three positions, all differing, and in all it exhibits the same tendency, that of growing towards the sun. I have observed that since the rainy and dull period has come, this propensity is not manifested so strongly as it was in the very hot weather. I would be glad to learn if any one else has observed the same tendency exhibited by this plant.

It is not a large variety of plants which we should aim at in our flower gardens, it is not botanical collections that please the eye in modern flower gardening, but a few well-chosen yet distinct colours, well contrasted, and each bringing the other colour boldly out.—G. DAWSON.

CUTTING DOWN OLD PEACH TREES.

THE Rev. Mr. Radclyffe in a recent communication to this Journal says he has given his Peach trees their autumn management. I have lately had some old Peach trees put under my care, and as I am anxious to do my best with them, I should be much obliged if Mr. Radclyffe would tell me how he manages his trees. I read an account of his mode of management some time back, but I had then no old Peach trees, and as I send THE JOURNAL OF HORTICULTURE away after I have read it, I cannot refer to it.—S. C.

[Some years ago I cut the trees down as near to the stump as my gardener (now dead), thought prudent, probably on an average to from 2 to 3 feet from the stumps. Were I now to cut such trees down, I would cut them closer to the stump. The perpendicular roots were all cut off, and the surface roots were cut off in a radius of 30 inches round the stumps. The ground round the stumps was then renewed with black dung and fresh mould. Since the period of cutting down I have renewed the whole of the surface soil. As the crop this year on the three trees was heavy (560 Peaches), I dressed the stumps and surface soil three times with the residue of beer-barrels, mixed with three or four times the quantity of water. After this was put on I copiously watered the whole of the ground so dressed.

As regards the autumnal after-management referred to by "S. C." on the removal of the hexagon netting, I cut off all the second growth of wood close to or within an inch of the wood previously pinched. The average length of the wood pinched would be from 6 to 8 inches. The forewood is spurred. I disbud but very little, as I am persuaded that depriving the tree of foliage is not good for it; and that in the case of the base and centre of the trees, it leads to bareness. The wood is ripening well, and there will be plenty left after any winter demolitions that may take place.—W. F. RADCLYFFE.]

THE ANT TRAP.—Procure a large sponge, wash it well and press it dry, which will leave the cells quite open; then sprinkle over it some fine white sugar, and place it near where the ants are troublesome. They will soon collect

upon the sponge and take up their abode in the cells. It is only necessary to dip the sponge in scalding water, which will wash them out dead by tens of thousands. Put on more sugar, and set the trap for a new haul. This process will soon clear the house of every ant.

ARABIS LUCIDA VARIEGATA, OR GOLDEN ARABIS.

I THINK it was in reply to some inquiries of Mr. Robson that I made some remarks last autumn about this lovely hardy edging plant. Another year's experience of it on a much larger scale has fully confirmed my conviction that, since the introduction of *Cerastium tomentosum* as a white or grey edging plant, there has not been so really lovely and easily managed an edging plant added to our parterres as this Golden Arabis. What the *Cerastium* is as a white or grey edging, this Arabis will ultimately become as a golden. It is one of the most unique imaginable where a straight front boundary line is required. An idea of its fitness and beauty when closely planted in long lines cannot be formed from seeing a few individual plants. Here it has been the object of admiration to all who have seen it. I need scarcely say that it is as hardy as a daisy, and easily increased by division either in spring or autumn. It requires very little labour to keep it tidy, as all that is needed in this respect is to pick the flowers off immediately they show themselves in spring. It is never so fine when planted in sandy or hungry soil as when well cultivated.—D. THOMSON, Archerfield Gardens.

WORK FOR THE WEEK.

KITCHEN GARDEN.

CONTINUE to destroy weeds wherever they appear. Clear away the yellow leaves from Broccoli and Brussels Sprouts, and any decaying vegetable matter wherever met with. To prevent the attacks of slugs on young Lettuces or Cauliflower plants mix soot and lime in equal proportions, and dust the plants with the mixture once or twice a-week. Cabbages, make good the blanks that may have occurred in the plantations of Cabbages or Coleworts, and keep a large reserve to make plantations in spring, as well as to fill up the blanks caused by the winter. We must expect frost soon, and ought to prepare accordingly. Lettuces, for instance, that are just coming into use may be lifted with balls, and placed in frames. Onions, look over those that have been stored, and remove any that are beginning to decay. Radishes, make the last out-door sowing, which, if the winter do not set in early, may prove useful. Spinach, see that it is thoroughly thinned and well hoed in favourable weather, and in every way encouraged. Tomatoes, in late situations where they are just ripening, let them be gathered and ripened off in the houses, as the least frost is fatal to them.

FRUIT GARDEN.

The principal operations in this department are gathering fruit when it is in proper condition, making preparations for filling up blank spaces on the walls, trenching ground for orchard trees and fruit plantations, which should be well done to insure success. Planting may now be done; mulch and stake safely without delay. Continue to keep the runners removed from the Strawberries, and those that have been some time potted for forcing should now be placed in a sheltered situation to insure their not being too much soddened with wet. Strong pricked-out plants may still be potted with good success, if placed on a kindly bottom heat. Keep the fruit-room cool and airy, examine the fruit frequently, and pick out any that are found to be decaying.

FLOWER GARDEN.

October is the most eligible time of the whole year for alterations, planting, &c., and whether planting or general ground work, operations should be carried forward with vigour as soon as possible. Such matters should not be allowed to press on the ordinary business of the garden, extra work requires extra labour, and if such is not supplied a corresponding amount of injury must occur in some other department. Alterations carried out during the autumn are doubly important, both on account of the season for

planting, turfing, and such operations, and also on account of the busy character of the spring months, which always bring sufficient claims on the most diligent, without the presence of extras of any kind. Remodelling flower-beds, or making new ones, may be carried on after the middle of the month, and where old beds are to be broken up the herbaceous plants already existing should be numbered or named in due time, in order to be able to ascertain the heights, colours, &c. Ornamental shrubs, whether evergreen or deciduous, may be removed with every prospect of success after the second week; no hesitation need take place as to the kinds, provided the ground is properly prepared by trenching, and thoroughly drained if necessary. The broom will now be in constant request, and although the varying tints of autumn are so admirable when contrasted on the trees, yet they are not so much admired on the lawn or gravel walks. We would now suggest a most liberal use of the roller on all lawns previous to the last mowing, this will leave the surface firm and smooth for the winter.

GREENHOUSE AND CONSERVATORY.

In arranging the stock in its winter quarters in these structures beware of overcrowding it. Drawn stock is not endured in these days, it is far better to throw a portion away than to spoil superior specimens. Many of second-rate character which require another season's growth, may be preserved in good dry pits, at least until the middle of December, when if very hard weather occur they may have a chance of removal, perhaps to some of the other structures until the end of January. It ought ever to be a maxim in regular plant-houses that no two plants touch, still we must confess that many who would admit the propriety of the principle are frequently compelled to ignore it in practice through want of sufficient accommodation. See that Epacries and other winter-flowering plants are placed in a part of the house where they will be fully exposed to the sun, so that the wood may be well ripened and free blooming insured. Examine frequently Heaths and other plants subject to mildew, and apply sulphur as soon as it is perceived. Water to be very carefully given at this season, especially in the case of large specimens, for there is much more danger of over-watering now than when the weather is warmer and the plants more active; therefore, look over the plants frequently and never water until it is absolutely necessary. Any of the late-growing Heaths which may be in want of more pot room may still be shifted, but do not expose them to cold winds, and water very carefully afterwards, for the roots cannot be expected to progress very rapidly at this season. Let everything requiring it be neatly tied at once.

STOVE.

Forcing must be avoided as much as possible, still the cold nights must not be permitted to affect the temperature so as to check materially the declining growth. Fall into winter treatment as quietly and naturally as you can; to accomplish this without sensibly affecting the healthy appearance of your plants is a great desideratum, and with care quite within the reach of the anxious cultivator.

FORCING-PIT.

This important and indispensable erection now begins to claim our attention. It may be termed the workshop of decorative horticulture, for it is out of this department that ornament and perfume must be obtained. Greenhouses and conservatories always afford some flowering specimens even in the midst of winter; but aided by this auxiliary they may be stocked at all times during the winter and spring months with suitable subjects in bloom. Take in an ample supply of all kinds of shrubs fit for this purpose. This will apply more particularly to American plants. All kinds of Dutch bulbs must also be immediately potted and plunged in a convenient situation ready to be removed, when wanted, to the forcing-pit.

PITS AND FRAMES.

Early-struck cuttings to be removed to shelves in the greenhouse or pits. If cuttings are now taken from Chrysanthemums showing bloom, put three in a 48-sized pot, and placed in a nice heat, they will soon root and bloom beautifully for decorating the front of stages or clumps.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE dry weather having caused Spinach to come up rather late, instead of sowing again we planted a number of rows, taking up patches of from three to five young plants, and putting them in rows some 6 or 7 inches apart. These, supplied with a little clean water, are now doing well. In our stiff soil we do not make a practice of thinning Spinach much, but rather cut out the young plants for use, and leave it on the whole rather thick for winter. We find that we have a better supply from not thinning it much in the rows. In rich, light land we think it would be as well to thin the August sowing in September, to about 4 or 6 inches apart. What is the best way to cook Spinach? The only time we tasted it truly delicious, it was thus managed. The heads and leaves were washed well, and allowed to drop all the water possible from them in an open sieve, then turned into a saucepan and boiled or rather steamed with their own juice. The chief of the cuisine told us that boiling in water spoiled it. Certainly as we tasted it it was delicious.

Cabbages.—Planted a piece with our forward plants that had previously been pricked out, lifting them with small balls, and setting them in soil which had been well exposed to the air after the Onions were taken off, in rows 2 feet apart, and 1 foot from plant to plant in the row. This width is necessary if the crop is to stand over the second autumn and winter. A clergyman who is a good gardener told us the other day that he made it a point at one time to pull up a spring Cabbage as soon as he had cut from it, but that now he sees the propriety of leaving the stumps to produce more. From many of our plants, besides the fine one Cabbage in early spring or rather summer, we have had three or four nice Cabbages in summer and autumn, and now these plants have each heads consisting of from five to a dozen nice young Coleworts. If thus left, 2 feet from row to row is not too much. Did we merely take the first Cabbage, 1 foot from row to row would be enough, and a vast amount of cutting would be obtained in little room. What we said lately on leaving all the old leaves and prunings of heads, &c., between the rows, will be found appropriate. In addition to rough hoeing, we would manure-water the whole of the old piece if we could. It is generally a rare fillbasket until the spring, if the winter is not very severe. If thus treated with a little enriching in autumn, they boil as sweet as young Coleworts; but it is well to encourage both. Coleworts, now heading, were planted about 12 inches apart, and have had in this bright weather a little sewage water.

Onions.—Sowed a few lines for succession to those sown in August. If the weather in winter should prove open, these will be best for spring transplanting, as the earlier-sown would be too forward. We prefer transplanting for early bulbs to allowing the plants to remain where sown. In stiff heavy land, if the plants remain where the seeds were sown in autumn, the earth should be scraped away from the surface of the bulbs, as otherwise they are apt to come long-necked. Tied up a lot of summer Onions in strings of different sizes, so that larger or smaller ones may be had at once as wanted. The White Spanish and the Tripoli we like best for autumn sowing. It is only by autumn sowing and transplanting that we can hope to rival the foreign imported Onions. This season the Onions are firm and sound, and fair as to size, but not so large as usual on account of the drought. This second summer after the rains is making all look bright and promising again.

Cauliflowers.—Pricked out more as previously stated, and watered those bearing, and successive crops, with sewage water. A nice crisp Cauliflower is what we find people never tire of unless presented in too great quantity.

Mushrooms.—Spawned the first piece in a shallow bed in the Mushroom-house, and just surfaced it with a little fresh droppings. We will allow it to remain a few days before earthing-up. Our beds in the open shady shed are covered, so that we have no need to hunt the pastures, and the home-grown are far more juicy and fleshy than those in the open fields. Before we took to the open shady shed in summer we used to be troubled with thin maggoty Mushrooms in houses in July and August, but we have now

no difficulty in producing them as sound and firm as at Christmas.

It is much to be desired that our friends would respond to the wish of the Editors by trying the experiments recorded at page 257, as we fear we cannot afford the time ourselves; and if we did the result would be of little use to us, as we have already detailed how by rich surfacings of Mushroom-beds we obtained the Mushrooms too thick and massive for successful cooking. If we were sure that such heavy Mushrooms would be desirable, then we might strive to obtain them; but at the weight spoken of we do not see how they could be cooked without slicing them into a number of pieces. From our knowledge of the antipathy felt by the Mushroom for lime when at all active, and other reasons, we must confess ourselves a little sceptical of the whole affair; but still we would be glad if others with more leisure would carefully conduct the experiments. The farmer's son was no fool who, after attending a course of chemical lectures, said he found out that muck made Barley grow, though he had a strong suspicion of this truth before he was indoctrinated with scientific farming. We have hitherto relied for Mushroom crops on muck in a certain condition; but if by a cleaner chemical process we can obtain them healthy and suitable for the table, why, by all means let us have them.

Capsicums, Tomatoes, Cucumbers, &c., as in previous weeks.

COTTAGE GARDENS.

We are glad that able men are doing what we attempted to do many years ago—namely, showing the connection between a well-managed garden and a clean, well-managed, comfortable house. There will, no doubt, be exceptions; but the flowers in the window, and plants and vegetables in the garden, give us a sort of key to the character of the inmates of the cottage. On this account, whatever value we might put on allotments at a distance, we would never place them in comparison as to advantage with a garden close to the homestead, where even a few spare minutes might be profitably spent.

There are just two ideas here which we wish to ventilate. The first is in connection with the subject of well-kept cottages. Marks of approval in different ways are often bestowed on the best-kept cottage gardens. As a general rule, we think the conclusions are formed at too early a period, if only one visit is paid to the gardens. It would be better if these were inspected late as well as early in the season, or, perhaps, at three seasons in the year—say April, July, and October. We are all, unless very lazy and unthrifty, aroused by the beauties of spring, and we dig, and plant, and sow, and clean, and brush, as if we would be insulting all that is beautiful and harmonious around us, if we allowed anything like untidiness and filth to appear. We are apt, however, to treat our gardens much as many people treat their houses—give them one good clean-up in the year, and then just a brush and a promise at times. As we obtain the produce we think less of neatness, and thus it often happens, as any person may notice in passing along the highway, that the garden that is a little paradise in May and June, is too much the garden of the sluggard in October and November, overrun as it is with decayed vegetables polluting the air, and weeds of all sizes left alone in their glory. After the winter vegetable are put in and cared for, every decaying bit of vegetable ought to be covered in the manure heap, and every spare bit of ground turned up to the ameliorating influences of the atmosphere. Some of the marks of commendation for cottage gardens should be retained for their found condition at this latter time, and the position of the refuse heap, the slop-hole, and how managed, should be taken into consideration, as well as how these matters would bear on the health and comfort of the inmates of the cottage. Cottage gardens in general in the autumn are much behind the mark, and as such exert a deteriorating moral and social influence.

The other idea is just this—many possessors of cottage gardens have complained to us that their efforts at neatness, nicety, &c., were undervalued, because they had wrought or did work in a garden. They have complained that they were disqualified from taking commendations or prizes on account of their daily work, and that prizes were taken by tailors, shoemakers, and artisans, who had more time in their gar-

dens than they had. Where there are many of such garden labourers in a village or neighbourhood, it might be advisable to let the competition be among themselves. Where this is not the case, or no rule to the contrary exists, we do not think that working in a garden ought to be any cause for disqualifying them from contending for the place of honour. True, they may be more conversant with the routine work, and know more about the best kinds of vegetables, and thus far have an advantage over their fellows who follow other avocations; but they labour under a great disadvantage in the very sameness of their usual day work for their employers, and the evening work for themselves. To the tailor and the shoemaker, and many other artisans, working in the garden is a delightful change. The work, in fact, becomes rest in labour. The tramping, and the digging, and the wheeling give a zest and preparation for the usual toil. Apart from the advantage and the pleasure to be gained, there can be no great rest in digging for oneself on an evening after digging for an employer all day. This depressing influence should be kept in mind, as well as the advantages such labourers possess; and duly allowed for, there will be little difference between them and other labourers and artisans. The feeling of satiety from long continuance at one kind of work is perfectly natural. The recognition of it has led to the proverbs about the smith's mare and the shoemaker's wife being ill shod. It explains the reason why, generally, with many exceptions it is true, farmers are such careless gardeners. They are occupied with their farming pursuits during the day, and gardening is such a near neighbour to farming, that the former furnishes no zest in the way of a change. You will have no difficulty in finding among farmers men of scientific knowledge, good chemists, and attentive students of natural history, whose gardens would not compare with those of some of their labourers. The truth is, when they have a little time they like a pursuit that takes them farther away from their daily avocations.

Among fruit and flowers our work was chiefly a continuance of what was reported in previous weeks. The flower garden, but for the falling leaves, still looks fair—R. F.

COVENT GARDEN MARKET.—OCTOBER 1.

Supplies continue good; fruit is very plentiful; vegetables of most kinds abundant. Some foreign Hamburgh Grapes of middling quality have arrived. Melons are becoming more scarce; Pines are sufficient for the demand; Oranges are more plentiful in consequence of the arrivals of autumn fruit from Madeira; and as heavy importations may be expected shortly, prices have fallen. As regards Apples and Pears we have nothing fresh to report.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

STORING FILBERTS (*Stella*).—These, as well as Cob-nuts, should be left in the husks, put into earthenware jars, and placed in a cold damp cellar.

VERONICAS (*M. H.*).—As there are about 130 species, exclusive of a multitude of varieties, we cannot undertake to publish their names and colours. If you refer to the "Cottage Gardeners' Dictionary" you will find them there.

BUSH PEAR AND APPLE TREES (*An Old Subscriber*).—To give "full particulars," such as you require, would require a whole page of our Journal. Buy Rivers's "Minature Fruit Garden."

BUNSEN'S BURNER.—In answer to "G. S." it may be obtained at any philosophical instrument maker's, and at many of the large gasfitters' shops in any large town. I do not remember the exact price, but it is only a few shillings.—A. W. W.

CINERARIA WANTED TO BLOOM (*Gardener*).—As the plants are now throwing up their bloom-stems, and you wish them to flower, you must not stop or pot the plants, but place them near the glass, and admit abundance of air, guarding against injury from green fly by fumigating with tobacco on its first appearance. They will bear slight forcing, a temperature of from 45° to 50° being warm enough; but they must be kept close to the glass, affording at the same time abundance of fresh air.

FUCHSIA LEAVES SPOTTED (*E. M. W.*).—We do not observe anything the matter with the leaves except that they are assuming their autumn tints, and appear as if splashed with thin whitewash, which may be due to syringing the plants with water holding lime in solution. In other respects the leaves appear healthy.

ORANGE TREE FROM A PIP (*Idem*).—It will bloom most assuredly; and how it has been growing for ten years without blooming is a puzzle. We have bloomed them frequently at four and six years old. If you are tired of waiting, you may graft it in spring, plunging the pot in a hotbed in April, and when it breaks or sends out shoots, put in grafts by side-grafting, leaving a couple of inches of the scion below the union, so that this heel may dip into a phial containing water, fastened by the neck to the stem of the stock, at a suitable height. You may also inarch, which is the surest of all modes of grafting, or bud it; in the latter case putting in the eyes from half-ripened wood, any time from June to August. The operation is performed in the same way as with Roses.

CINERARIA MARITIMA AND CENTAUREA CANDIDISSIMA PROPAGATING AND WINTERING (*T. S.*).—This Cineraria, you say, is not hardy with you; and such is the case in many places, for this simple reason—the soil is too damp and rich. On dry gravelly soils, and on rockwork, it is perfectly hardy; and the way we keep it over the winter is to transplant it in autumn to the foot of a south wall, where we allow it to remain until spring, when we plant in its proper position, and by dividing the large roots obtain sufficient plants to fill the space previously occupied. In some soils and situations Cineraria maritima will not live. You may, therefore, take up a few plants and pot them in any light loamy soil, keep sparingly supplied with water, and winter in a dry airy situation in the greenhouse. In February place in a temperature of 55° or 60°, which will encourage the production of side-shoots. When these are of sufficient size to make into cuttings of three joints, cut them across transversely below the lowest leaf, and remove it and the next above it, leaving one with the growing point at top. Insert the cuttings in moist silver sand, and plunge the pot in a bottom heat of from 75° to 80°. Place a bell-glass over the cuttings if the atmosphere of the house is dry, but if it is calm and moist the bell-glass may be dispensed with. Keep the sand moist, but avoid wetting the foliage. If the sand be kept very wet the cuttings will damp off. They will root in a fortnight or three weeks, and may then be potted. Continue them in heat until established; then remove to the greenhouse and gradually harden-off prior to planting-out. Centaurea candidissima requires the same treatment, only the cuttings must be taken off close to the stem of the old plant, so as to have a heel; and they should not be planted out so soon by a month, or not before the beginning of June. These Cinerarias may be raised from seed sown in February; but the foliage is not so bright in colour as that produced by cuttings from old plants.

GERANIUM LEAVES TURNING YELLOW (*Gardener*).—We are unable to detect anything the matter with the leaves enclosed, and think they are yielding to natural decay through age. Want of water at the root may have hastened their early maturity. In other respects we do not see anything the matter with them. You may cut the plants down now, and they will push again before winter; and when the shoots are an inch or two long they may be potted, reducing the ball considerably. Such plants will bloom splendidly next year in April and May.

SEA-KALE FORCING FOR CHRISTMAS (*Idem*).—To have it ready at Christmas the roots should be placed in a temperature of from 55° to 60°. Under the stage of a stove will do well, and an inverted flower-pot, with the holes stopped up, will answer for blanching the shoots, putting it on in the second week in November. If you force the plants where they grow, hot dung should be placed on the pot about the same time, or six weeks before it is wanted for use. The roots will not do to force twice. The shoots are weak enough from the early forcing, and they are useless for forcing again before a matured growth takes place.

GRAPES SHANKING (*J. W. H., Lancashire*).—As the Vines did so well last year, would it not be advisable to try them another year? Perhaps they had too heavy a crop or wanted watering, if ever they do want it in Lancashire, for in the south it has been so dry. However, if you resolve on raising the roots, you cannot do it too soon to secure fresh roots. The material you speak of (the top spit of a pasture), will do very well if thrown up at once. It will do with little lime if you take a thin film of turf off, which will make a nice heap for potting, and use the other turf after the grass is removed 2 or 3 inches deep. When turf is used at once, and then with a good deal of grass in it, it is apt to heat too much. Move the flags.

NAME OF DIANTHUS (*W. F.*).—It is one of the legion of Indian Pinks not one of which has a name. Seeds from it would produce plants not one of the flowers of which, probably, would be like those of the parent.

PEACH-HOUSE (*A Seven-years Subscriber*).—We think your proposed arrangements will answer very well. We would have preferred a double ridge-board, covered with your cap at apex, the ridge-boards a foot apart, and a swing ventilator between them. We would move the two pipes close to the front farther in by 2 or 3 feet, if you mean to plant the trees there, within 15 inches or so of the glass. You have ample piping, six rows (four might do); but you are quite right to have six, as they need never then be too warm; and you will be able to coat them with sulphur from the time the buds break, and that is the best safeguard against red spider. Such a house would be best with its ends north and south, or its side south-east and north-west, and, a true span would look best. We presume one side of your's faces the north considerably, and that, too, will answer well enough. We do not see clearly the object of having pipes in the chamber, beneath the outside border for the early house, to be covered with glass, under the present arrangements; but if, in addition to the 9 or 12 inches of rubble beneath your 2½-feet-deep border, you placed open conduits of pipes, such as small round drain-pipes, every 3 feet or so across the bottom of the house, among the rubble, and raised these lines of pipes in several places above the surface of the border at the back, then these two pipes in the chamber would give a mild heat to the border throughout when you commenced forcing. The top of the pipes at back might be plugged, and opened when a moist air was deemed necessary. You will not have too many trees at first; but most likely two trees for each side will ultimately be enough, unless you root-prune. For such a house half-standards will be better than standards. **Early House (Front).**—One dwarf Erluge Nectarine, one Violette Hâtive ditto, one half-standard Noblesse Peach. (Back).—Half standards: one Early Grosse Mignonne Peach, one Barrington, one dwarf Violette Hâtive or Bellegarde. **Late House (Front).**—One dwarf Walburton Admirable Peach, one dwarf Téton de Venus, one half-standard Roman Nectarine. (Back).—One half-standard Peach, Salway, one Galande or Chancellor (if very late), one dwarf Pitmaston Orange Nectarine.

VINES IN BALCONY VINEYARD (*A Five-years Subscriber*).—The Apples sent are Barchard's Seedling, corect, a good cooking Apple; and the other is the Winter Greening, a first-rate keeping Apple for kitchen use. For your raised balcony, greenhouse, and vineyary, we would prefer that the border for the Vines should be made partly under the balcony, and also in front of it; and we would plant the Vines in front of the pillars, and enclose them in a three-sided wooden case, placed against the pillars, and the stems packed in sawdust. As this house, 15 feet by 10, is to contain Camellias, Rhododendrons, &c., with Vines overhead, and to be heated solely from the sitting-room, the door of which can be left open from 10 P.M. until 7 A.M., we would recommend that in severe weather in winter the fire should be replenished at bedtime. Everything will be safe enough if the soil in the Camellia pots do not freeze. If a small boiler were placed at the back of the fireplace, and pipes taken from it, the house would be still more secure, and the room-door might be shut at night. As the back wall of the house is now supplied with a Sweetwater Vine, and that is a beautiful Grape when well grown, we would not have more than four Vines on the roof, one at 3 feet from each end and the other two equally divided. To make the most of the Sweetwaters the house should be kept rather close when they are in bloom; and several times during the day in sunshine the dry hand, or a dry feather, should be drawn over the bunches, so as to promote free setting. But for your objecting to the flavour of the Black Hamburgh, we would have recommended you to have two Hamburghs and two Royal Muscadines in such a house; but as you must have the Muscat flavour, we would advise two plants of the Muscat Hamburgh and two of the White Frontignan. The Muscat Hamburgh was very fine in Mr. Lane's orchard-house last season, but that house is now heated. For variety you might have one Muscat Hamburgh and one Esperione, or one Lady Downes', which would prolong the season of Grape-gathering. We have ripened White Frontignan without fire heat. If you had not a Sweetwater against the back wall, we would have recommended Buckland Sweetwater; but though a nice Grape, and hardy, it has no Muscat flavour, which you wish; and although the berries of the White Frontignan are rather small, they are exceedingly rich, and for our own eating we prefer them to the Muscat of Alexandria. For strong Vines that would give you a little fruit next season, with not less than 9 feet of good stem, you would have to pay, we presume, from 5s. to 15s. each, according to strength and prominent eyes. We would advise you, however, not to take much from them the first season. For such Vines the first thing to be avoided is stagnant water, and, therefore, a drain from the border will be necessary. Above that it will be advisable to have a foot of rubble, of clinkers, stones, brickbats, &c., and then from 18 to 24 inches of soil. If fresh rough loam all the better; and it may have a tenth part of brick rubbish and a twentieth part of rotten dung mixed with it, along with eight or ten bushels of broken or bruised bones. We would use little coco-nut refuse, but a few bushels will do good. We would prefer a rather thick muslin for shade in early spring, fixed on the roof inside by rings. It will keep out nearly as much cold as frigi domo, and it will be more pleasant to look through during the day. After the Vines grow and fill the house, such a shade will not be wanted after May. The blinds may be hooked on with rings, a foot or so from the glass.

PELARGONIUM (*T. S. S.*).—The variety to which you refer has not as yet been sent out.

ALLIGATOR PEAR (*D. C.*).—Sow the pips in equal parts of loam, peat, and leaf mould, next March, and plunge the pots in a hotbed at 80° or 85°. When up and growing repot, and place in a stove, giving them the same treatment as stove plants generally. Unless you have room to accommodate a goodly-sized Apple tree in your stove you will make poorly out in growing this tree for its fruit, for it attains a height of 40 feet. It is from the West Indies.

STRUTHIOPTERIS GERMANICA (E. G. H.).—By Struthiopteris germanica we conclude you mean Struthiopteris germanica, or Ostrich Feather Fern, which is quite hardy, and will grow in shaly rockwork and shrubberies. It forms noble circular crests of great elegance and beauty, often 3 feet across, and increases rapidly by underground stolons, and the neighbourhood soon becomes densely covered. It is from central Europe. It is fully described in our "Fern Manual."

FRAME LIGHTS (Melon Grower).—The most suitable lights are those made of well-seasoned red deal, though pitch pine is a more durable timber. The frame should be made strong, but as light as possible, the sides and ends of the lights 3 by $2\frac{1}{2}$ inches, morticed and tenoned at the corners. You may have, at equal distances apart, three sash-bars, $1\frac{1}{2}$ by $2\frac{1}{2}$ inches, narrow side upwards, which will be rebated three-quarters of an inch for the glass to rest on. This will require glass $9\frac{1}{2}$ inches wide, and $21\frac{1}{2}$ inches long, which is the size we would have. Twenty-one-ounce sheet glass of good quality will answer perfectly. Any carpenter can make the lights, but you will be well served by any of the horticultural builders who advertise in our columns.

POTTING AGAPANTHUS UMBELLATUS (C. M. Major).—You may pot this beautiful African Lily immediately after it has done blooming; and remove the offsets from *Lilium giganteum* at the time of potting, which may be now or in March. We do not know in what way you could facilitate the ripening of the *Lilium* seed-pods, unless by an increase of heat, and exposure to more intense light.

CUTTINGS OF VARIOUS PLANTS (Idem).—Half-ripened shoots of *Bougainvillia* will strike freely at any time in a mild bottom heat, and so will cuttings of *Passiflora*, which may be taken now, but we like them a little earlier. The best time to take cuttings of *Escarilla rubra* and *Acacia longifolia*, is when they have half-ripened shoots upon them, or young growths of a firm texture to the touch, which should be put in as early in the summer as possible. Cuttings of any plant will root much more freely in the early part of summer than in the autumn.

MOVING BUDDED BRIARS (W. A.).—You may remove them safely any time in November. They will move more safely at that time than if they were allowed to remain another year before moving. November, February, and March are the best seasons for removing them. The former period is best.

ORNITHOGALUM THYSOIDES (E. G. H.).—We do not know the variety *alba*. *Ornithogalum thyrsoides* is from Natal in South Africa, and all but, if not quite, hardy. Being of doubtful hardiness it should have the protection of a cold pit or cold greenhouse. It should be potted in September in pots of a suitable size, 6 or 8-inch, in light turf-loam two-thirds, leaf mould one-third, with a free admixture of sand. Peat is preferable to leaf mould, unless the latter be of good quality, but a little of both will not be amiss. It is not unusual for the plant to show bloom at Christmas, throwing up stems from 1 to $1\frac{1}{2}$ foot high, with a spike of snow-white flowers having a yellow centre arranged in the form of a sceptre. The flowers individually are of a good size and neatly formed, opening at the bottom first, and in many cases more than fifty flowers will be borne on a spike, and occasionally one hundred. It blooms for three or four weeks if not kept in a high temperature, and has the property of remaining in full bloom in a cut state in water. It is both easy of cultivation, and one of the best things introduced of late years.

CALCEOLARIAS IN EXPOSED POOR SOIL (Idem).—We have them this year on a poor light soil over gravel, and they have done famously. We might as well let you into the secret of how we accomplish this when others have failed even on strong soil, such as the Calceolaria likes. In November we take out the soil to the depth of 2 feet, place 6 inches of fallen tree leaves at the bottom, and then replace the soil. We plant the beds with bulbs, such as Crocuses, Tulips, &c.; and when these come off, by the first week in June, 6 inches of well rotted manure is forked into the bed, and trodden firm. We plant and give a good soaking of water, and afterwards twice a week until the plants become established, and a sprinkling overhead on the evening of hot days. In July we mulch the beds with an inch of Mushroom-bed dung, and give a thorough soaking of water, and in ordinary seasons we have splendid beds, and never finer than this year, especially of yellow. Should the summer prove dry we water twice a week, every other time with liquid manure. *Canariensis*, *Aurea floribunda*, *Amplexicaulis*, *Rugosa major* (a hardy early kind), *Sage's Yellow* (a strong-growing kind), *Yellow Dwarf*, *Cloth of Gold*, and *Yellow Prince of Orange* are excellent yellow sorts, which we find do well on light soil with the above treatment.

BOOK (Perseverantia).—“The Cottage Gardener’s Dictionary” will, perhaps, suit you. If you wish to have fuller botanical descriptions you must have Loudon’s “Encyclopædia of Plants.”

NAMES OF FRUIT (H. R.).—1, Styrian; 2, Catillac; 3, Beurré Diel; 4, Chanmontel; 5, Beurré Langelier; 6, Bishop’s Thumb; 9, Franklin’s Golden Pippin; 11, Downton Pippin. Others not identified. (*St. Leger*).—1, Bull’s Golden Reinette; 2, Nelson Codlin; 4, Dutch Mignonette; 5, Ribston Pippin; 6, Broughton; 8, Fasse Colmar. Others not identified. (*New Forest*).—1, Belle et Bonne; 2, Crasanne; 3, Comte de Lamy. (*C. T. J.*).—2, London Pippin; 3, Lamb Abbey Pearmain; 5, Yorkshire Greening; 6, Scarlet Nonpareil; 9, Beurré Diel; 10, Piles’ Russet. Others not identified. (*G. H.*).—1, unknown and worthless; 2, Golden Reinette; 3, Dumelow’s Seedling; 4, Chester Pearmain; 5, unrecognised; 6, Selwood’s Reinette. (*B. A. N., Shrewsbury*).—21, Herefordshire Pearmain. The others unknown and very inferior. (*A. E.*).—The Grape No. 1 wants more heat. The specimen is abortive. Graft a Black Hamburg upon it. No. 2 is very little better. We cannot identify either. (*J. Everett*).—1, Yorkshire Greening; 2, Dumelow’s Seedling, apparently, but a wretched specimen; 3, Kerry Pippin; 7, Gravenstein; 9, Beauty of Kent. The others were undistinguishable.

NAMES OF PLANTS (Ciciley).—We reply—1, *Athyrium Filix-femina*; 2, *Lastrea ciliata*; but there is little evidence in the wretched scraps sent. Correspondents who send such specimens must suppose us to be magicians. (*J. S.*).—1, *Lastrea Filix-mas cristata*; 2, *Lastrea spinulosa*; 3, *Lastrea Filix-mas*; 4, *Lastrea Filix-mas paleacea*. (*F. C.*).—*Plumbago L’epenæ*, we think, but the flowers were much crushed. (*A. B.*).—1, *Nephrolepis tuberosa*; 2, *Pteris cretica*. (*An Old Subscriber*).—1, *Dabecia foliolosa*; 2, *Erica vagans*, var. *alba*; 3, *Chelone glabra*; 4, *Seems* to be a scrap of *Linaria striata*; 5, Apparently some *Boragewort*, but we cannot name it without the flowers. (*W. L.*).—We cannot name your tree without seeing the flower.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOW AT THE AGRICULTURAL HALL, ISLINGTON.

OCTOBER 1ST, 3RD, AND 4TH, 1864.

We believe we are correct in stating this is the first Show held under the immediate patronage of the Poultry Club. The building leaves nothing to desire, and its management by Mr. Douglas deserves high commendation. There are few places in the United Kingdom where fowls can be cared for as judiciously as they were here. We use the word advisedly, because in some places kindness and good intentions unwisely directed do more mischief than any neglect. The perfect cleanliness visible everywhere was pleasing, and the most fastidious could detect no unpleasant smell.

The Show was looked forward to by amateurs as the first test of judging by rules. The Club, however, does things by halves. After a troubled labour of twelve months the rules should be ready, and they should be public. When the catalogue is headed by the announcement, “Under the Patronage and Management of the Poultry Club,” each class should have a copy of the rules by which the birds were judged. This would explain many things that should be understood by exhibitors, and still more by those who fill the office of Judge. Where liberty of action is denied, and a man is pinned to rules, it is no longer the decision of a Judge, but the verdict of a book. If that book were in our hands we should probably have little to say; but as it appears to be printed only for a few, we must judge the tree by its fruits.

There was a very good class of *Dorkings*, but in this, as in all others, Lady Holmesdale’s pens were empty. The first and second prize birds were good; but in our opinion pen 17, belonging to Captain Hornby, was the best pen in the class. In Class 2, for White and Silver-Grey *Dorkings*, the first-prize Silver-Grey cock had a black and white breast. We preferred Mr. Lingwood’s White *Dorkings* to the Rev. G. F. Hodson’s. We liked Mr. Boyle’s pair of pullets, but could find no merit in Mr. Sutherland’s.

The first-prize *Spanish* were very good. We did not at all like the second-prize birds. It was a poor class. We liked Mr. Boyle’s second-prize *Brahmas* better than Mr. Barclay’s first. These latter were vulture-hocked, which has not hitherto been deemed desirable.

The *Cochin* prizes would have been reversed according to the old system of judging. Mr. Chase would have been first. Capt. Heaton’s birds are sadly out of condition. The White *Cochins* were the best and largest class we have seen for some time, but here we should have altered the awards, by putting the third first.

The *Game* did not come up to the old standard. Twisted combs and squirrel tails were not approved formerly, but they were plain in some classes. In Class 23, a third prize was given to two pullets with distinctly red deaf ears. In Class 27, Mr. Duxbury’s Black *Hamburgs* were every way superior to Mr. Beldon’s, which had first prize.

In the variety of *Bantams* we cannot understand why *Piles* that contribute one pen, should override a good class of *Ducklings*. In the *Gold* and *Silver-laced* we liked Mr. Jones’s second better than Mr. Spary’s first. The cock in the latter had a very narrow comb.

The Spanish cock in 381 had a distinct thumb mark in his comb, and the *Brahma*, 398, was a poorly-conditioned bird.

We liked the second-prize *Rouen Ducks* better than the first.

The *Geese* were excellently judged. We have thus reviewed the 509 pens which composed the Show of Poultry. We know little of *Pigeons*, and the gentleman who promised to report upon them was unable to attend.

We have been obliged to report of this Show differently from our usual method. It may be that impartiality in reviewing a show is as difficult as strict veracity is in history, according to Lord Macaulay. We were unwilling to trust entirely to ourselves for this reason, and, therefore, consulted many others. Their testimony agrees with our own. We have reviewed this Show as the test of judging by rules. We have felt throughout it was an unthankful task. Our

feeling has been, that book-judging is impossible. We are more than ever convinced that it would break up exhibitions; but if it is desirable that it should be adopted, let the rules be published and canvassed by those who have the greatest interest in them. It is manifestly unfair to Judges to publish that they shall decide by rules which are unknown to those who have to report on the judgments.

DORKINGS (Coloured, except Silver-Grey).—First, J. Frost, Parham, Suffolk. Second, R. W. Boyle, Dublin. Third, C. Priest, Worthing. Highly Commended, A. Stamford, Eatons, Sussex; J. Anderson, Meigle, Forfarshire; Capt. Hornby, Prescot. Commanded, R. W. Boyle.

DORKINGS (White or Silver-Grey).—First, A. Anderson, Meigle, Forfarshire. Second, Rev. J. F. Newton, Kirby-in-Cleveland. Third, Rev. G. F. Hodson, North Petherton. Highly Commended, H. Lingwood, Needham Market, Suffolk. Commanded, Sir St. G. Gore, Bart., Wirksworth, Derbyshire.

DORKINGS (Coloured or White).—First, R. W. Boyle, Dublin. Second, R. E. Posans, Brentwood. Third, J. Sutherland, Mulinar. Highly Commended, R. W. Boyle.

SPANISH.—First, W. Rose, Bristol, and J. Rodbard. Second, A. Heath, Calne, Wilts. Third, W. Cannon, Bradford, Yorkshire.

BRAHMAS (Dark).—First, W. T. Barclay, Leyton. Second, R. W. Boyle. Third, C. Priest, Worthing. Fourth, H. Lacy, Hebden Bridge, Yorkshire. Highly Commended, H. Lacy; C. Priest.

BRAHMAS (Light).—First and Second, J. Pares, Chertsey. Third, J. Clarke, Ciswick.

BRAHMAS.—First, R. W. Boyle. Second, J. Hinton, Hinton, near Bath. Highly Commended, W. T. Barclay, Leyton. H. Lacy, Hebden Bridge.

COCHINS (Brown or Partridge).—First, T. Stretton, Orm-kirk. Second, E. Tudman, Whitchurch, Salop. Third, Cartwright, Oswestry. Highly Commended, Rev. G. W. Hodson, North Petherton, Bridgewater.

COCHINS (White or any other colour).—First, W. Dawson, Hopton, Mirfield. Second, F. W. Zurhorst, Dublin. Third, Rev. F. Taylor, Keastwick, Westmoreland. Highly Commended, R. Chase, Birmingham; G. Lamb, Wolverhampton; H. Yardley, Birmingham; F. W. Zurhorst, Commanded, F. W. Zurhorst.

COCKS (Cinnamon or Buff).—First, Capt. Heaton, Manchester. Second, Rev. W. C. H. D'Aeth, Arfordfield, Reading. Third, R. Chase, Balsall Heath, Birmingham. Highly Commended, H. Bates, Birmingham; J. Crosland, jun., Wakefield; Capt. Heaton, Commanded, Rev. C. Spencer, Atleborough.

CHICKENS.—First, J. Crosland, jun. Second, F. W. Zurhorst, Dublin. Commanded, H. Bates; F. Gardiner, St. Peter Street, Islington.

GAME (Black Reds).—First, T. Dyson, Halifax. Second, W. T. Everard, Leicestershire. Third, A. D. Dyas, Madeley, Shropshire. Commanded, S. Matthew, Stowmarket.

GAME (Brown or other Reds, except Blacks).—First, Second, and Third, J. Fletcher, Stoneclough.

GAME (Duckwings, Greys or Blues).—First, E. Aykroyd, Bradford. Second, S. Matthew, Stowmarket. Third, J. Fletcher, Stoneclough. Commanded, S. Matthew.

GAME (White or Piles).—First, S. Matthew. Second, J. Fletcher. Third, Miss E. Crawford, Farmsfield, Notts.

GAME (Any other colour).—Prize, J. Fletcher, Stoneclough.

GAME (Reds).—First, J. Fletcher. Second, Sir St. G. Gore, Bart., Wirksworth, Derbyshire. Commanded, J. Wood, Wigan.

GAME (White or any other colour).—First, J. Hulsall, Ince, near Wigan. Second, J. Fletcher, Stoneclough.

POLANDS.—First and Third, G. C. Adkins, The Lightwoods, near Birmingham. Second, H. Beldon, Bingley.

HAMBURGS (Gold-pencilled).—First, T. H. Ashton, Tamworth. Second, C. M. Royds, Rochdale. Third, F. Pittis, jun., Newport, Isle of Wight. Highly Commended, J. Robinson, Garstang.

HAMBURGS (Silver-pencilled).—First, Sir St. G. Gore, Bart., Derbyshire. Second, J. Robinson. Third, Mrs. H. Sharp, Bradford.

HAMBURGS (Golden-spangled).—First, G. H. Hyde, Ashton-under-Lyne. Second, Sir St. G. Gore, Bart. Third, J. Roe, Hadfield, near Manchester.

HAMBURGS (Silver-spangled).—First, H. Beldon, Bingley. Second, T. Davies, Newport, Mon. Third, Mrs. H. Sharp, Bradford.

HAMBURGS (Pencilled).—First, J. E. Powers, Biggleswade, Beds. Second, Sir St. G. Gore, Bart.

HAMBURGS (Spangled).—First, H. Beldon, Bingley. Second, Sir St. G. Gore, Bart.

ANY OTHER VARIETY.—First, H. Beldon, Bingley. Second, N. Sykes, Esmond Road, Old Ford. Second Extra, Miss C. H. Ballance, Taunton. Third, H. Saville, Rufford Abbey. Third Extra, F. W. Zurhorst, Dublin.

BANTAMS (Red Game).—First, J. W. Kelleway, Merston, Isle of Wight. Second, Miss E. Crawford, Southwell, Notts. Third, Rev. G. Raynor, Brentwood. Highly Commended, J. Crosland, jun.; Sir St. G. Gore, Bart.; J. Munn, Stoneclough; R. B. Postans, Brentwood, Essex; R. Swift, Southwell, Notts; Capt. Wetherell, Loddington.

BANTAMS (Any other variety).—First, R. Swift, Southwell, Notts. Second, J. W. Kelleway, Isle of Wight. Third, J. Home, Prescot, Lancashire.

BANTAMS (Gold or Silver-laced).—First, W. Sparry, Dunstable. Second, E. Jones, Clifton. Third, W. Sparry. Commanded, E. Jones.

BANTAMS (Black or White, Clean-legged).—First, Sir St. G. Gore, Bart. Second and Third, F. Pittis, jun., Newport, Isle of Wight.

BANTAMS (Any other variety).—Prize, F. W. Storey, Daventry.

DORKINGS (Coloured or White).—First, C. Priest, Muntham Court, Worthing. Second, Rev. J. G. A. Baker, Biggleswade. Highly Commended, R. W. Boyle; C. Priest. Commanded, A. Stamford, Ashurst, Surrey; H. Lingwood, Suffolk.

SPANISH.—First, E. Draper, Northampton. Second, W. R. Bell, Newport Pagnell. Commanded, A. Heath, Calne, Notts.

BRAHMAS.—First, J. Wright, Suffolk. Second, W. E. Hammond, Ipswich. Highly Commended, R. W. Boyle; J. Hinton; H. Lacy; J. Wright. Commanded, W. T. Barclay, Leyton.

COCHINS (Cinnamon or Buff).—First, C. E. Reddale. Second, F. W. Zurhorst, Dublin. Highly Commended, Capt. Heaton, Manchester; H. Bates, Birmingham.

COCHINS (White or any other colour).—First, F. W. Zurhorst, Dublin. Second, E. Tudman, Whitchurch, Salop.

GAME (Black-breasted Reds).—First, Hon. W. H. W. Fitzwilliam, Rotherham. Second, A. D. Dyas, Madeley, Shropshire.

GAME (Brown-breasted or other Reds except Black).—First, T. Statter, Manchester. Second, J. Wood, Moat House, near Wigan.

GAME (White or any other colour).—First, P. Jones, Drayton, Salop. Second, Sir St. G. Gore, Bart.

HAMBURGH (Pencilled).—First, H. Beldon, Bingley. Second, F. Pittis, Newport, Isle of Wight.

HAMBURGH (Spangled).—Prize, Sir St. G. Gore, Bart.

BANTAMS (Game).—First, J. W. Kelleway, Merston. Second, M. Aukland, Chesterfield. Third, J. Muir, Shawcough, Manchester. Highly Commended, Sir St. G. Gore, Bart.; R. Swift, Southwell, Notts; M. Turner, Preston. Commanded, Rev. G. Raynor, Brentwood.

DUCKS (Aylesbury).—First, Second, and Third, J. K. Fowler, Prebenda Farm, Aylesbury.

DUCKS (Rouen).—First, R. W. Boyle, Dublin. Second, C. Pease, Southend, Darlington. Third, W. T. Barclay, Leyton. Highly Commended, T. Statter, Manchester; J. Rodbard, Wrington, Bristol.

DUCKS (Any other variety).—First and Third, T. H. D. Bayley, Biggleswade. Second, F. W. Earle, Prescot, Lancashire. Highly Commended, T. Statter, Manchester. Commanded, Miss C. H. Ballance, Taunton.

GEES (White).—Prize, R. W. Boyle, Dublin.

GEES (Grey or Mothed).—First and Second, R. W. Boyle, Dublin. Third, Mrs. M. Seamons, Aylesbury.

ORNAMENTAL WATER FOWL.—First, Second, and Third, H. Saville, Rufford Abbey.

TURKEYS.—First, J. Smith, Stafford. Second, R. W. Boyle, Dublin. Third, W. Wright, Fulbourn, Cambridgeshire. Highly Commended, P. W. Storey, Daventry. Commanded, W. Wright.

PIGEONS.

POWTERS (Cocks).—First, G. R. Potts, Sunderland. Second, R. Fulton, Deptford. Third, F. Else, Bayswater. Highly Commended, R. Fulton, Deptford; S. Robson, Brotherton, Yorkshire. Commanded, P. Eden, Salford. (Hens).—First and Third, G. R. Potts. Second, P. Eden, Salford. Highly Commended, P. Fulton, Deptford. Commanded, J. Steib, Liverpool Road, Islington; G. R. Potts.

CARRIER COCKS (Black or Dun).—Cup, P. Eden, Salford. Second, T. Colley, Sheffield. Third, A. P. Leite, Manchester. Highly Commended, F. Else, Bayswater. Commanded, T. Colley; A. P. Leite.

CARRIER HENS.—First and Second, T. Colley, Sheffield. Third, F. Else, Bayswater. Highly Commended, P. Eden, Salford; F. Else.

TUMBLERS (Almond).—First, P. Eden, Salford. Second, F. Else, Bayswater. Highly Commended, J. Ford, Monkwell Street, London; F. Else; M. Hall, Old Bethnal Green Road.

SHORT-FACED (Tumblers).—First, J. Percival, Rye Lane, Peckham. Second, H. Morris, Forest Hill, Kent. (Mottled).—First, P. Eden. Second, F. Else, Highly Commended, P. Eden. Commanded, C. J. W. Rudd, (Balds or Beards).—First, H. Morris, Forest Hill. Second, J. H. Esden, Hammersmith. Highly Commended, F. Else; D. Fosick, Barnsbury.

TURBITS.—First, M. Wicking, Blackheath Park. Second, F. Else, Bayswater. Highly Commended, H. Yardley, Market Hall, Birmingham.

OWLS.—First, G. H. Sanday, Holme Pierrepont, Notts. Second, P. Eden. (The whole class Highly Commended.)

FANTAILS.—First, M. Wicking, Blackheath Park. Second, R. F. Jarvis, Holmesdale, Kent. Highly Commended, F. Else; J. W. Edge, Ashton-Newtown, Birmingham; S. C. Betty, Gloucester Gate, Regent's Park.

JACOBINS.—First, M. Wicking. Second, C. Bulpin, Bridgewater.

TRUMPETERS.—First, C. Bulpin, Bridgewater. Second, F. Else. Highly Commended, W. H. C. Oates, Newark, Notts. Commanded, J. R. Robinson, Sunderland; H. Yardley, Birmingham.

RUNTS.—First, T. D. Green, Saffron Walden. Second, J. Hardwill, Tanton.

BARBS.—First and Second, P. Eden.

ANY OTHER NEW OR DISTINCT BREED.—First, Rev. C. Spencer; A. P. Leite. Second, M. Wicking. Third, A. Heath; H. Yardley. Highly Commended, H. Yardley; A. Heath, Calne, Wilts; S. C. Betty, Regent's Park.

CARRIERS (Except Blacks or Duns).—Cocks.—First and Second, W. H. Edmonds, Broadway, Westminster. Hens.—First and Second, J. C. Ord, Pimlico. Highly Commended, T. Colley, St. Philip's Road, Sheffield. Commanded, W. Smith, Gray's Inn Road.

MAGPIES.—First, C. Bulpin, Bridgewater. Second, M. Wicking, Blackheath Park.

DRAGONS.—First, J. Percival. Second, T. Whitley, jun., Halifax.

Highly Commended, W. Massey, Gedney, near Wisbeach; H. Yardley.

NUNS.—First, M. Wicking. Second, J. W. Edge, Birmingham.

RABBITS.

LONGEST EARS.—First, J. Cranch, Portland Lawn. Second, W. Lock, Beresford Street, Walworth Road.

GREATEST WEIGHT.—First, J. Cranch. Second, W. Lock.

BEST COLOUR.—First, H. Hanford, Wilford, Nottingham. Second, Hall and Co., Plumstead. Highly Commended, Miss M. Hawksley, Edgware Road. Commanded, W. Philipps, Copenhagen Street, Islington; H. Hanford; J. Cranch; J. P. Millar, Whitechapel Road.

WOODSTOCK AGRICULTURAL SOCIETY'S POULTRY SHOW.—SEPT. 20TH.

ARRANGEMENTS had been made for a supply of pens from London, but from some cause they did not arrive, and the Committee were driven at the last moment to make the best provision they could. The Duchess of Marlborough won both the champion prizes for the best pens in the show. The Dorkings and Cochin-Chinas were a very superior class, and the Show generally was very creditable.

SPANISH.—Chickens.—Prize, F. S. Dodd, Hampton Poyle.

DORKING.—Prize, H. L. Gaskell, Kiddington. Chickens.—Prize, Duchess of Marlborough.

BRAHMAS.—Chickens.—Prize, Duchess of Marlborough.

COCHIN-CHINA.—Prize, F. S. Dodd. *Chickens.*—Prize, F. S. Dodd.
HAMBURGS (Spangled).—Prize, J. James, Woodstock. *Chickens.*—Prize, W. Heath, Kidling on.
HAMBURG (Pencilled).—Prize, J. James. *Chickens.*—Prize, W. Heath.
GAME.—*Chickens.*—Prize, R. Pratt, Woodstock.
GOSLINGS (White).—Highly Commended, J. Prior, Woodstock.
GESE (Grey).—Prize, Duchess of Marlborough. *Goslings.*—Prize, H. L. Gaskell.
DUCKS (Aylesbury).—Prize, Colen Bowyer, Steeple Aston. *Ducklings.*—Prize, Duchess of Marlborough. Highly Commended, Colonel Bowyer.
DUCKS (Coloured).—Prize, C. Fowler, Bicester. *Ducklings.*—Prize, S. Druse, Eynsham.
TURKEYS (Black).—Prize, Duchess of Marlborough. *Poults.*—Prize, H. L. Gaskell.
TURKEYS (Grey).—Prize, Colonel Bowyer. *Poults.*—Prize, Colonel Bowyer.

Judge, Mr. James Turrill, of Oxford.

ELLESMERES POULTRY EXHIBITION.

THIS forms part of the Oswestry District Agricultural Society's Exhibition, which it is wisely proposed shall be held in a different town each year. This arrangement adds very much to the interest of any similar meeting, as fresh localities are thereby enlisted in the undertaking, and, consequently, the novelty rather increases at each annual repetition than the contrary.

The Show, which was held on September 29th, proved a decided success; so much so, that the attendance of visitors must have shown an incredible increase; and the quality of the poultry present, equally with the number of pens entered, bore evident marks of improvement likewise. On referring to the catalogue we find entries from Knowsley, Birmingham, Bristol, Liverpool, Aylesbury, and even from such a distance as Dublin. This shows as strongly as could be that the public feeling is now interested in the success of the undertaking, nor do we doubt that eventually this Society will rank highly among our poultry shows. A little confusion as to the numbers when compared respectively with the pens and the printed catalogue was the only drawback to the proceedings, and we trust that in future years a similar occurrence will be especially guarded against.

The Game classes took foremost position, the Brown Reds and Black Reds being very good ones; but the Duckwings were far from so satisfactory in plumage as could be desired. The hackles of the cocks were mostly dark listed down the centre of each feather, or what is perhaps equally objectionable, mixed irregularly with black patches. We mention this shortcoming in the hope of preventing a selection by their owners in future years so fatal to prize-taking. Some very good Grey Dorkings were shown, but some of this variety were exhibited in very bad condition indeed. There were several pens of good Cochins shown, particularly the White ones from Mr. Zurhorst, of Donnybrook, Dublin; the Partridge-coloured ones of Messrs. Tudman and Cartwright respectively; and the Buffs of Mr. Bates, of Birmingham. There were also good Hamburgs, but Mr. John Robinson, of Vale House, Garstang, Liverpool, monopolised all four prizes in these classes. All Bantams competed together, and, most strangely, none but Game Bantams were entered. Most of these wanted age to make them fit for the show pen, though not a few bore traces of very careful breeding.

The Turkeys were excellent; and the Geese were especially objects of public interest, on account of their immense development of both bone and flesh. The Aylesbury Ducks were better than the Rouens, and weighed well, Mrs. Seamons's first-prize pen being 22½ lbs. the three birds; Miss Shaw's, second-prize birds, were 21½ lbs.; and even the highly commended pens were 20 lbs. and 21 lbs. respectively. From these weights it may be presumed that they were of unusually excellent character as a whole class. Among the "Extra poultry" were a pen of capital White Decoy or Call Ducks. The weather throughout was as fine as possible, so much so, that not a spot of rain fell to mar the happiness of the day. Everything, therefore, passed off most pleasantly, and the whole undertaking proved a decided success.

GAME (Black-breasted and other Reds).—First, T. Whittingham, Bather-ton, Nantwich (Brown-breasted Red); Second, S. Johnson, Nantwich (Black-breasted Brown). Highly Commended, T. Burgess, Burleydam, Whitchurch; A. B. Dyas, Madeley, Salop (Red); J. Tomley, Whittemere (Black-breasted); W. Gamon, The Green, Thornton-le-Moors, Chester (Black-breasted). Commended, W. Drury, Harleston, Nantwich, Cheshire (Black Red); P. H. Cooke, New Marton (Brown-breasted); W. Gamon (Brown-breasted Red).

GAME (Any other variety).—First, A. B. Dyas, Madeley, Salop. Second, J. B. Chune, Severn Cottage, Coalbrookdale. Commended, Miss Sadler, Heath Cottage, Whitchurch.

DORKINGS.—First and Second, Miss Davis, The Lache, Chester. Highly Commended, E. Shaw, Plas Wilmot, Oswestry; E. Tudman, Ashgrove, Whitchurch; W. Gamon, The Green, Thornton-le-Moors, Chester.

COCHIN-CHINA.—First, E. Tudman, Ashgrove, Whitchurch (Brown or Partridge). Second, P. Cartwright, Oswestry (Partridge).

COCHIN-CHINA (Any other variety).—First, T. W. Zurhorst, Bellville, Donnybrook, Dublin (White). Second, H. Bates, Harborne Heath Cottage, Birmingham (Buff).

SPANISH.—Miss Davis, The Lache, Chester (Black). Second, E. Shaw, Plas Wilmot, Oswestry (Black).

HAMBURGS (Pencilled).—First and Second, J. Robinson, Vale House, Garstang, Liverpool.

HAMBURGS (Spangled).—First and Second, J. Robinson, Vale House, Garstang, Liverpool. Commended, C. Cooke, Breadenheath, Whitchurch.

GAME AND OTHER BANTAMS.—First, S. Owen, Ellesmere. Second, T. Hassall, Whitchurch. Highly Commended, W. Gamon, The Green, Thornton-le-Moors, Chester. Commended, C. R. M. Owen, Erway, Ruabon; T. Burgess, Burleydam, Whitchurch.

TURKEYS.—First, Miss Davis, The Lache, Chester. Second, T. Burgess, Burleydam, Whitchurch. Highly Commended, R. Topham, Elson, Ellesmere; R. Lewis, Sycamore House, Hordley.

GESE.—First, Mrs. Seamons, Hartwell, Aylesbury. Second, T. Burgess, Burleydam, Whitchurch.

DUCKS (Rouen).—First, J. Holme, Knowsley, near Prescott. Second, W. Gamon, Thornton-le-Moors. Highly Commended, J. Nelson, Heaton Mersey, Manchester.

DUCKS (Aylesbury).—First, Mrs. Seamons, Aylesbury. Second, Miss E. Shaw, Oswestry. Highly Commended, Miss E. Shaw; Mrs. Seamons. Commended, B. W. Winn, Llanford Hall.

EXTRA POULTRY.—Highly Commended, G. Williams, Oswestry (White Call Ducks).

Mr. Edward Hewitt, of Sparkbrook, Birmingham, officiated as the Judge.

MIDDLETON AGRICULTURAL SOCIETY'S POULTRY SHOW.

(From a Correspondent.)

THE sixth annual Exhibition of the Middleton Agricultural Society took place on the 22nd ult. We published the prize list last week. The entry of Poultry, Pigeons, and Rabbits numbered 500, being about 100 pens in excess of last year. About 20,000 visitors were present, £588 being received for admission at the doors.

The principal classes were for chickens, and this neighbourhood being famed for Hamburgs, the competition was in many cases very close.

Red Game headed the list. Brown Reds were first and second. The cockerel in Mr. Wood's first-prize pen was late in feather, but a good chicken. Mr. Fletcher's second-prize pen were in much better condition; both cockerel and pullet were, however, rather defective in feet. In the single cockerel class a good Black Red was first, and a Brown Red second. In Game any other variety, a good pen of Piles took precedence, capital Duckwings being second. In Single Cockerels a white-legged File was first, and a Duckwing second. A silver cup, given by a few amateurs, was offered for a pair of Game pullets, and produced no less than forty-one pens, containing many good pullets. The cup was awarded to Mr. John Crosland, jun., for a splendid pair of Black Reds. Mr. Wood was second with a good pair of light Brown Reds, and Mr. Aykroyd third with an unusually good pair of Duckwings. The competition between the three pens placed was very severe indeed, the Judges had great difficulty in arriving at a conclusion, the pens being so evenly balanced in every point, Reds at length obtaining the preference. Several pens received commendations. Spanish were unequally matched in the winning pens. The first-prize pen contained a poor cockerel. For Single Cockerel a very even good-faced bird took first. Dorkings and Brahmans formed good classes. In Cochins, Mr. Stretch was first with Partridge, good in shape and feather, but not a match in colour of legs; Capt. Heaton was second with a very fine pen of Buffs. For Single Cockerels excellent Buffs were first and second; and for a Pair of Pullets Capt. Heaton took first with good Buffs; Partridge were second. The Hamburg classes were well filled, most of the prize birds being excellent, although we noticed some crooked in bone. In Silver-spangled there was a falling-off in good cockerels; Gold-spangled were better; Blacks were capital. For Any other variety, Black Polands were first, and Silvers second; while for Single Cockerels the positions were reversed. In Bantams made up good classes, any age being allowed. In Game good Black Reds won for cock and two hens; while

Game good Black Reds won for cock and two hens; while

for cockerel Black Red was first, and Brown Red second. In Bantams any other variety, Gold-laced were first, and excellent Blacks second.

In *Ducklings*, Aylesburys, Mrs. Seemons suffered a defeat, the first prize being awarded to a very fine pen belonging to Mr. J. Hartley. Rouens were also good.

The *Pigeons* were not numerous, but some very choice birds were exhibited, many of which, however, did not receive notice; in fact, the best pen was passed over. In Almonds the worst pair were first, Mr. Eden having to be content with the second position. In Carriers splendid Blacks won. In Powters the best pair of Blues, belonging to Mr. Eden, were not noticed. Jacobins were chiefly noticeable for odd eyes. In Fantails crested birds were first, and a fine pair of plain-headed second. In Owls the first went to poor Whites, the second to very coarse Silvers, Messrs. Eden and Fielding's fine Whites not receiving notice. In Nuns the first-prize pen contained a pair with odd eyes, the second were fair birds. In Any other variety a pair of splashed Trumpeters were first, and Black Barbs second; while a much superior pen of Barbs was unnoticed.

POULTRY JUDGES.

As one of the exhibitors I attended the Agricultural Show recently held at Middleton, and was sorry to hear the complaints current as to the character of the poultry judging, the awards accorded to some of the classes being of a nature to make it evident that the Judges were not competent for their task. It is not denied that one of the Judges is well qualified to decide on the merits of some kinds of birds, such as the Spanish, Hamburghs, &c.; and it is the more to be regretted that he should have undertaken to pronounce on the deserts of classes, where he had to rely more on the opinion of others than on his own judgment.

Judges must bear in mind that many of the exhibitors whose fowls they judge understand the peculiarities of those kinds which they are in the habit of rearing and exhibiting quite as well as the Judges themselves; and that the decisions of the latter are certain to be canvassed and scrutinised, and if they do not approach tolerably near to correctness will not fail to be condemned. It is, therefore, a great mistake when Judges undertake to decide on claims, often conflicting, between the several competitors in a class where the knowledge of the exhibitor is superior to their own; and they would confer an incalculable benefit by confining themselves to the classes with which they are acquainted. On the other hand, a contrary course frequently inflicts irreparable injury on the cause of poultry exhibitions. It occasions disappointment and well-grounded discontent among the contributors, and if permitted to occur with anything like frequency would ultimately defeat the object of these shows in the improvement of the various kinds of fowls, and also break up the exhibitions altogether.

One of the Stewards of the late Middleton Show, who possesses a good knowledge of the qualities of birds, I was glad to observe, was fully sensible of the anomalies in the poultry judging, and candidly admitted them when pointed out to him, expressing his sincere regret at their occurrence, intimating that they should not recur in any future Show.

Before closing this line, allow me to explain that it is not out of a captious or unfriendly disposition towards any party that I have taken up the pen, but in the interests of the exhibitors and exhibitions; and the circumstance that the only mode whereby what is wrong can be remedied is submitting it to the ordeal of public investigation, will be a sufficient apology for troubling you with this communication.—J.

BEEES, WASPS, AND IVY BLOSSOMS.

In a letter which I have received from my cousin, Mr. George Fox, of Kingsbridge, in the county of Devon, he gives a most interesting account of what has fallen under his notice, with respect to the ivy blossoms and the wasps. As his letter was not intended for publication, I extract the substance for the edification of others.

The bloom of the ivy in the neighbourhood of Kingsbridge is more abundant than has ever been known before. Down

a lane, known as the Back Lane, it may be seen in the most splendid luxuriance, the blossoms swarming with flies and wasps, the latter being in such numbers as to appear like a swarm of bees in the air. In the neighbourhood of Exeter at this date, the 27th of September, the ivy blossom is not much opened; and as for wasps, numerous as they have been, we have been troubled by very few within the last two weeks. But in Kingsbridge an almost Egyptian plague of wasps still exists.

Up to ten o'clock on the 26th, about the ivy in the lane, bees, flies, and wasps, were almost equally divided, the bees somewhat exceeding the wasps in numbers. An extraordinary excitement prevailed among all the bees in Mr. G. Fox's apiary in consequence of the great supply of honey and pollen. Although the day continued uninterruptedly fine and warm—external thermometer in the shade 63°, barometer 30.35—on revisiting the locality of the ivy bloom at two o'clock not one bee was to be seen on the ivy, very few flies, but thousands upon thousands of wasps. Every bunch of flowers had three or four wasps upon it. His bees had become suddenly quiet, but were about mignonette, fuchsias, &c., as usual. The wasps had established a perfect monopoly of the ivy, and the bees must have felt intimidated at their overwhelming numbers, and deserted the otherwise tempting pasture.

Last year, when wasps were comparatively scarce, the bees gained considerably in weight from the ivy blossom; but now it seems as if the bees had agreed to surrender the field unconditionally to the wasps. My correspondent concludes by expressing his belief that the pith of this matter is worthy of investigation by the entomologists of the day, irrespective of its singularity and interest to the apriarian.

I have told the tale of this close observer of nature in an imperfect manner, and without having obtained permission from him to do so. I wish he could be induced to give, from his own pen, the readers of the Journal the benefit of his observations more frequently. He has promised me that he will relate his experience with hives made of a new material. I trust he will do so, and that before long, as I am sure it must interest all apriarians.—S. BEVAN FOX, Exeter.

[We heartily coincide with this concluding wish.—EDS.]

QUEENS' EXCURSIONS—COMB PLATES.

Has Mr. Woodbury ever known young queens to take flights after positive evidence of impregnation?

Has he ever known virgin or drone-breeding queens lay eggs in the same year as they were hatched?

What is the longest period which has ever come under his observation between hatching and impregnation?

Can he inform me of the composition of the metal plates for making wax sheets?—S.

[Although the fact has never come under my own personal observation, I consider it proved on indubitable evidence that queens sometimes again take flight after a perfectly successful wedding trip. Huber was, I believe, the first who observed it, and his testimony has recently been confirmed by my accomplished apriarian friend "J. E. B." I have also just come across an article by Otto Rothe, a clever German apriarian, on this very subject, in which he states it as certain that some queens who have already returned with the sign of impregnation will yet take wing afterwards. He relates, in support of this conclusion, an instance in which he witnessed a young queen return with unquestionable evidence of her excursion having been successful on the 25th of last April. On the 27th she again took flight, apparently without any result, and a subsequent examination of the interior of the hive and the brood found therein, proved that the object of her flight must have been fully accomplished on the 25th.

I have on more than one occasion known drone-breeding queens lay eggs the same season in which they were themselves hatched.

The longest period I ever knew between hatching and impregnation occurred in 1862, when I had a queen which laid no eggs till she was thirty days old, so that she must probably have been twenty-seven or twenty-eight days old before making a successful wedding trip. Her worker sisters appeared to manifest impatience at this unusual delay, inas-

much as I found her rigorously imprisoned more than once; but ultimately all turned out right, and, as before stated, she commenced laying worker eggs when thirty days old.

Plates for impressing artificial combs are made of type metal.—A DEVONSHIRE BEE-KEEPER.

BEES AT THE EXHIBITION OF THE WHITWORTH AND ROCHDALE AGRICULTURAL SOCIETY.

We learn from the *Rochdale Observer* that "In centuries long past the good people of Rochdale every year, in the month of August, made an excursion into the marshes lying round the town to gather rushes to strew the stone or mud floors of their churches and chapels through the chill winter months. When the use of rushes for carpets had been superseded by less barbarous expedients the people preserved the memory of the custom by the pantomime of dragging a monster rushcart through the town for the edification of their friends and visitors. But in process of time this pantomime fell into evil hands and disrepute, becoming merely the excuse for a gross public scandal; and at last this scandal was suppressed by the public voice, the name only remaining to keep alive the recollection of a fine old religious custom."

"The great feature of the rush-bearing week, for several years past, has been the exhibition of the Whitworth and Rochdale Agricultural Society; and this year that Society has had probably the most successful, and certainly the most satisfactory, of its meetings.

"With regard to the extra stock, the palm must be awarded in this class to Mr. John Wrigley's collection of bees. These bee-hives were a great point of attraction, and throughout the day by far the most interesting collection on the field to many visitors. Mr. Wrigley was literally besieged. The collection consisted of an observatory-hive, a bell-hive, a unicomb-hive, a cottage-hive, with a super containing 25 lbs. of honey, and a comb of last year's honey, containing 20 lbs. of the precious store. To those who have followed the recent newspaper controversy as to the habits of the bee it must have been especially interesting to watch the movements of the bees. For several hours a violent fratricidal war was carried on, and to the drones Wednesday was a day of merciless slaughter. Penned up in their hives as they believed for the winter, the little bees occupied themselves most gallantly in driving out their big brothers and uncles, twisting their wings, hunting them to the bottom of the hive, and there summarily dispatching them by a process of lynch law. The motive apparently prompting this measure was the instinct of self-preservation to protect themselves against starvation by the exhaustion of their honey before the return of spring with its flowers. No idle bee is ever tolerated within the hive. As soon as the slightest sickness or defect is discovered in a bee it is instantly hustled out of the hive, and left to die or recover, just as the case may be. The movements of the queen bee excited the liveliest interest and attention. She is the very arch-type of a constitutional sovereign—reigning without governing. Her subjects possess all the rights of a free people. They believe in the sacred right of rebellion; and when any especially gross act of regal tyranny has been perpetrated, when the sovereign prerogatives have been stretched beyond the constitutional point, not even the great English people can be readier than these little republicans to vindicate themselves against the royal authority. Not only are cases of deposition frequent, but occasionally the queen is put to the cruellest torture and death. Still, when all goes well, the bees are the most loyal and dutiful of subjects. They respect and reverence their queen to a degree which seems greatly out of character with their really high spirit of independence and self-assertion. We are assured by Mr. Wrigley that it is a gross libel on the bee to say, as the *Times* "Bee-master" says, that she is fond of a little beer. Bees may be tempted to indulge in fermented liquors, but—listen to this ye teetotallers!—both from principle and taste, they infinitely prefer a glass of clear cold water with a cinder and a few lumps of sugar."

CAUSING A SWARM TO SETTLE.—To prevent a swarm flying away, or to make one settle, take your longest garden

syringe full of water, and give them a gentle shower with a very fine rose, not vindictively to half drown them, but to give them a hint that they had better look out for shelter. I tried it first some years ago, and it has always been successful.—E. M. W.

ANALYSIS OF THE EXCRETA OF BEES.

VARIOUS opinions are held respecting the composition of the excrement of bees. While most persons regard the contents of the rectum as composed of the indigestible remains of pollen, Dr. Alefield recently declared them to be uric acid. An analysis of the excreta has shown the following ingredients:—

1. *Remains of pollen.*—I boiled the excrement in caustic potash lye, slightly diluted. After filtering, I washed the residuum in hot dilute muriatic acid. What was left after again filtering, could, from its insolubility, be only the remains of pollen. It appears under the microscope like an indistinctly granular mass.

2. *Uric acid.*—I immersed the excrement in concentrated sulphuric acid, in which uric acid remains undecomposed. After carefully decanting the liquid from the resulting carbonaceous mass, I added water; and then washed the precipitated matter in water. I now added one drop of *liquor ammoniae* and one drop of muriatic acid. On heating, the mass assumed a purplish hue—the characteristic action of uric acid.

3. *Hippuric acid.*—I boiled some excrement in caustic potash lye. After filtering, I added dilute muriatic acid, and obtained a precipitate which proved to be composed of uric and hippuric acid.

According to an approximate estimate, the excreta of bees consists of about one-third uric and hippuric acid, and the rest of indigestible portions of pollen.—(*Canada Farmer.*)

VOLATILE SOAP FOR REMOVING PAINT, GREASE, SPOTS, &c.—Four tablespoonfuls of spirits of hartshorn, four tablespoonfuls of alcohol, and a tablespoonful of salt. Shake the whole well together in a bottle, and apply with a sponge or brush.—(*Scientific American.*)

OUR LETTER BOX.

DISTINGUISHING GANDERS FROM GEESE (B. H. W.).—It is very difficult to speak positively as to the sex of Geese, and therefore all sorts of experiments are resorted to—some trust to one, some to another. The gander is supposed to have a shorter and thicker neck. He is said to have the bag between the legs single, while the goose has it double. In adult birds the sex may be discovered by examination. Many people try them with a dog. If the birds are shut up in a small place like a pigsty, and a dog put in, the ganders will all lower their heads and hiss at it.

BRAHMA POOTRA CHARACTERISTICS (A. G.).—There are light and dark Brahmams. You should choose one or the other. In the dark variety the cock should have a black breast, thickly spotted with white; dark tail, light hackle and saddle, black, or nearly black, thighs. The pulets are pencilled all over, except the hackle, which is black and white striped. Vulture hocks are not desirable. (*Brahma Pootra*).—The vulture hocks are great defects, but not disqualifications. The crooked breasts are not important.

POULTRY EXHIBITIONS (An Exhibitor of Poultry).—We insert in our list gratuitously every forthcoming poultry show that the secretary announces to us; and we ask all such secretaries to send the announcements.

GOLDEN PHEASANTS (W. H. B.).—Golden Pheasants are not productive till they are two years old. It is after the same time the cocks get their plumage. Barley is the best food, but they are fond of and require green food. They must have clean water. They are very hardy, and require little or no shelter. They may be allowed to run about in all weathers. If the house is not already covered, we advise you not to cover it. The birds do not require it, and any little gain by keeping out rain is more than counterbalanced by the loss of sun.

LONDON MARKETS.—OCTOBER 3.

POULTRY.

The principal feature in our market this week is the Goose trade for Michaelmas. It has been diminishing for years, but the trade has never been so bad as this time. It was difficult to find buyers at low prices. Michaelmas remains as quarter day, but it is forgotten so far as Goose-eating is concerned.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 59.8°, and its night temperature 41.7°. The greatest heat was 74° on the 15th, 1842; and the lowest cold, 24°, on the 15th, 1860. The greatest fall of rain was 1.04 inch.

BULBS FOR FLOWER GARDEN DECORATION.

(Continued from page 270.)

SCILLA.

OR margins and edgings to beds and borders these are very pretty dwarf plants. The prevailing colour is blue, though there are some white and pale rose varieties. They require the same treatment as Snowdrops, and like them should not be removed more frequently than is necessary for increase, or when the outline becomes broken, or the clumps too large. The flowers are in spikes of from six to twelve blooms, bell-shaped, and gracefully pendant. As edgings to beds of Hyacinths, or for marginal effect in beds of any kind, the Scillas are unrivalled by any plant in their colour during the early spring months.

Scilla sibirica, which is not more than 3 or 4 inches high, has the most charming effect of any plant I know as an edging to a bed of Cloth of Gold Crocus, if planted so as to form a band 6 inches wide; and round a bed of Hyacinths of red shades, a six-inch band of Scilla bifolia and an outer ring of S. bifolia alba are quite charming. The best white is probably S. campanulata alba, which is of free growth and a profuse bloomer. S. patula, a porcelain blue, with a good spike, and free in habit and blooming; S. campanulata (syn. belgica cerulea), fine blue; and S. amena, bright blue with erect spike, are the best out of about eighteen. S. peruviana, blue, has large erect trusses; and there is a white variety of it. Scillas are admirably adapted for marginal effect in window-boxes and baskets when associated with other bulbs. They will grow in all soils, those which are rather light being preferable, and they require a light open situation.

ERYTHRONIUM.

The Erythronium, or Dog's-tooth Violet, has ornamental foliage distinct from that of any other bulb, and has a fine effect when planted as an edging to beds of Hyacinths, always considering the shades of colour, so that a pleasing arrangement may be made. They are easy of cultivation, but like a light dry soil containing plenty of vegetable matter, as leaf mould. They do best,

however, in peat soil. Dried bulbs should have a little sand placed round them at the time of planting, otherwise they are very apt to decay in consequence of the absorption of moisture, whilst the root is rendered all but farinaceous through drying them. They should be planted about 3 inches apart and at the same depth; and when once planted they should not be again removed until they have increased too much, or until the soil becomes impoverished, which may be known by the weakness of the foliage. The best time to transplant them is immediately after the foliage has decayed. They should be replanted the same day; the largest roots being used for immediate effect, whilst those of less size are put in more closely together in places of minor importance. Erythronium americanum has yellow flowers, and is fine. Erythronium dens-canis and its variety major have purplish blooms; and the variety alba and its sub-variety major have white blossoms. The leaves are occasionally employed for decorative purposes, the bulbs being in that case potted and forced like Hyacinths.

HYACINTHS.

These are unrivalled (and so are all plants for some particular purpose if we only knew it), for producing effect either in beds of one colour, or in marginal lines, balcony-boxes, and ornamental designs, associated with other bulbs or in masses by themselves. The grand secret in forming beds of them is to plant in a line, ring, or bed of one colour, and one variety only, so that the drawback of "mixtures"—that is, different heights, colours, and periods of blooming—may be avoided, the aim being to obtain a bed or border of equal height, and with each colour appearing simultaneously. Mixtures, however, answer perfectly for borders and mixed beds, though not admissible except as neutrals in an arrangement of beds where an equal and uniform effect is desired. Bulbs of this description may be had at a cheap rate, and though not equal to those sold for growing in pots and for forcing, they make a splendid show in April. The colours are white, blue, red, and yellow in different shades. The Hyacinths usually employed for bedding are the second-sized bulbs, or such as have some disqualification for being grown in pots—as loss of name, commonness of sort, this being old, perhaps; yet they may be good sound bulbs, and calculated to make a fine show.

Miniature Hyacinths are nothing more nor less than matured small roots of named Hyacinths, which bloom finely for their size, and are therefore admirably adapted for small groups, edgings to beds or borders, baskets, or window-sill boxes or frames.

When the beds are cleared of their summer occupants it is time to prepare them for planting bulbs to bloom in April, May, and the beginning of June. Nothing is better than deep digging or trenching, placing at the bottom of each bed 6 inches of fresh or recently fallen tree leaves, which should be covered with a foot of soil; and they will serve to raise the beds considerably, and allow water to drain away freely. In the course of a

year the leaves will be pretty well decomposed, and on digging in the succeeding autumn they will be brought to the surface, and thus the soil will be enriched by a not-over-stimulating manure. Fresh leaves being put in every autumn, the beds annually receive a dressing of vegetable matter, which saves dung; and in dry summers especially the roots lay hold of the decomposing leaves, when the plants are becoming exhausted by blooming. No one thinks of thinning the bloom of bedding plants, and the consequence is that in summers like the past they bloom themselves to death. The beds being thus prepared, if the soil is free I simply plant the bulbs from 4 to 6 inches apart in lines, double rows being more effective than single, allowing the same distance between the two lines, and 1 foot between each pair of double rows. If in beds, 6 inches from bulb to bulb is a fair allowance. Insert the bulbs 3 inches below the surface; and if the soil is wet place a little dry sand around each, but on light soils this is unnecessary; then rake the surface and make it neat. The beds should slope from the centre to the sides, and the borders from the back to the front.

The bulbs should be planted from the beginning of October to the beginning of December, the middle of November being a suitable time. It is very desirable to plant in dry weather, for unless the ground is in good working order the bulbs are almost certain to become unsound, especially if kept in a very dry place previous to planting. About the middle of December the surface of the beds should be covered with an inch or two of partially decayed leaves, which serve as a protection against frost, keep the beds from becoming saturated with rain, and afford nourishment to the roots. By spring the leaves will be thoroughly decomposed by the action of the air, and be in a suitable state for being dug into the beds preparatory for bedding-out plants.

NARCISSUS.

Those known as Polyanthus Narcissus are as well adapted for planting out of doors as for pot culture, and a bed of them is at least novel and fragrant. They require precisely the same treatment as Hyacinths.

Garden Narcissus, as the Hooped Petticoat, Trumpet, Pheasant's-eye, and other varieties are usually styled, are admirably adapted for borders, and a bed or two may be desirable. The roots should be planted from the middle of October to the middle of November, but the earlier the better. Plant them about 3 inches apart, and the same depth, in ground stirred deeply, and in good heart. Planted in borders in clumps of from six to twelve bulbs they look well, and the flowers are very desirable for bouquets in spring.

Once planted it is not necessary to remove them oftener than once in three years, and then the bulbs should be put in as soon as the ground can be prepared for them, always renewing the soil if they are planted in the same place. It is not uncommon to see these roots left for years without any care whatever, and as they increase fast the clumps become large, and are poor in consequence. On taking them up it would be well to consider whether it may not be desirable to plant the smaller bulbs in woods near the outsides, by woodland walks, in the front of shrubberies, or in parks. The most suitable time to remove them is when the foliage decays.

The double white Narcissus is remarkable for its delicious odour; and the charming N. bicolor with white sepals, and funnel of yellow, is distinct and fine when it can be had true to name. The Trumpet Narcissus (N. maximus) is also fine; and the Sulphur Trumpet (N. moschatus) desirable. Pheasant's-eye (N. poeticus), pure white, with its cup variegated with red, will be in every garden; N. bulbocodium (Hooped Petticoat), is rich and effective; N. incomparabilis flore pleno or Nonpareil, Silver Phoenix, bicolorata or Orange Phoenix, not excepting bifrons, with its Jonquil-like flowers, and the Jonquils are all fine, but must yield to the glorious N. pseudo-Narcissus, or single Daffodil of our woods, and the Van Sion, or double.

TULIPS.

Probably no flower is so worthy of extensive cultivation for the ornamentation of the flower garden as the early single Tulips. They are very numerous, and many of them

are of little value for planting in masses, but having grown a number of them I can vouch for those named below being good bedders.

YELLOWS.

Canary Bird, rich pure yellow, attaining a height of about 9 inches. Pottebakker Yellow, yellow self, of good form, and effective; 9 to 12 inches. Due Van Thoi, yellow, early, and very dwarf; 4 to 6 inches. Yellow Prince, a good yellow, about 9 inches. Thomas Moore, orange, distinct; 9 inches.

WHITES.

Pottebakker White; 9 to 12 inches. Surpassed by none. Luna. A neat flower and very effective. Queen Victoria, fine form, but small; 9 inches. Jagt Van Delft, white self, fine form; 9 inches. La Laitière, white, heightened by an outer blue tint; fine; 9 inches.

SCARLET SHADES.

Typhon, crimson scarlet, rather small, but effective; 9 inches. Due Van Thoi, scarlet, very beautiful; 6 inches. Cramoisie fidèle, intense scarlet. Couleur Cramoisie, crimson scarlet, small, but fine. Vermilion Brilliant, the best of the scarlets; 6 to 9 inches. La Belle Alliance, rich crimson scarlet; 6 to 9 inches.

BLUE SHADES.

Florida, purplish violet, fine; 9 inches. Berangaria, a purple with a little mauve in it. Very fine. Archus, violet purple, lilac belt; 9 inches. Caiman, violet or puce, with lilac margin. La Plaisante, violet, with a slight rosy tint. Wouverman, violet purple; fine.

FEATHERED, STRIPED, AND TINTED IN VARIOUS SHADES.

Due Van Thoi, red with orange border, early; 4 to 6 inches. Keizerkroon, yellow ground, flaked vivid scarlet. Queen of the early Tulips. Royal Standard or Standard Royal, white ground, flaked with carmine. Alida Marie, white, tipped and flaked with cerise; extra fine. Bride of Haarlem, white bordered with crimson. Rosa Mundi, white, shaded rose; fine. Grand Duc, yellow and crimson. Rose Luisante, rosy crimson, peach edges. Due Major, rich red, margined orange yellow; 6 to 9 inches. Rose Tendre, white, feathered and striped crimson. Roi Pepin, white, striped or rather flaked with crimson. A new kind, and a great improvement. Ma Plus Aimable, a bronzy red flaked with orange; 6 to 9 inches. Standard of Gold, yellow, crimson tip; very gay.

DOUBLE TULIPS.

Tournesol, scarlet and yellow. The most effective Tulip in cultivation. 9 inches. Yellow Rose, yellow. The best yellow bedding Tulip. 9 inches. There is a variety of this with variegated leaves. La Candeur, white. The best of all whites. 9 inches. Rex Rubrom, crimson scarlet. The best of the reds. 9 inches. Imperator Rubrom, crimson scarlet; gay; 9 inches. Paeony Gold, golden yellow feathered with crimson; 6 to 9 inches. Couronne Pourpre, rich crimson; very effective; 9 inches. Mariage de la Fille, white, striped violet rose; 1 foot. Overwinnaar, white, barred and feathered violet purple; 6 to 9 inches. Gloria Solis, crimson with yellow border; 6 inches. Due Van Thoi, red and yellow; 6 inches.

There are in addition to these the Parrot Tulips, which have flowers of large size and brilliant colours, forming most effective groups in borders. Of these, Perfecta, scarlet and yellow; Constantinople, red; Feu Brillant, scarlet; Coffee Colour; Belle Jaune, yellow; and Monstre Rouge, crimson, are amongst the best.

Then there are late or rather show Tulips, which are not the fashion just now, but if ever a sight is worth seeing it is a bed of these under canvass on a bright day in early summer; but knowing little about Feathered Bizarres, Flamed Bizarres, Feathered Byblemens, Flamed Byblemens, Feathered Roses, Flamed Roses, and Selfs, I shall leave them to be disposed of by those more initiated in such matters.

Tulips like a deep rich soil, light rather than strong; but any kind will answer if free of stagnant water, and stirred to a depth of a foot or 18 inches. If very light a dressing of cool manure, as sheep or cowdung about a year old, spread an inch thick on the surface, and pointed in, will contribute to their vigour; but if the soil is very tenacious and heavy, the same thickness of sharp sand would be preferable. By all means plant in dry weather, placing the bulbs 6 inches asunder every way, but the smaller kinds, as the Due Van Thols, should not be more than 3 or 4 inches apart, planting them so that the apex of each may be covered 2 inches in wet soils, and 3 inches in those which are dry and loose; a covering of light mould, especially if the soil is heavy and wet, is conducive to success. Although Tulips will grow and flower if stuck into the soil in almost any way, yet they annually become weaker in growth, and fewer in number, until they at last disappear. Once planted they require no further

protection until the blooming is past, when they may be taken up with balls, if the foliage is fresh, and planted again in a similar situation, placing them the same depth in the soil, giving a good watering, and shading from hot sun for three or four days, after which remove the shading, and discontinue watering, when they will ripen their growth, and be little the worse of the removal. In most seasons, however, the foliage will be so far advanced as to allow of their being taken up by the first week in June, it being injurious to the roots to allow them to remain in the soil after the foliage exhibits a yellow hue. The bulbs should not be allowed to remain long in the ground after flowering, but should be taken up and dried before the foliage is quite gone. The most suitable time to plant is the first fortnight in November, and they may be planted up to January, but the later they are put in the later will be the bloom in the spring, and as this interferes with the planting of the summer occupants of the beds, early planting is advisable.

(To be continued.)

G. ABBEY.

MY ORCHARD-HOUSE.—No. 11.

THE season of the year is at hand for remodelling our orchard-houses; for replacing such trees as, from any cause, we do not wish to retain; for classifying varieties, and adapting them to those portions of the house which their habits seem to require; and for removing such sorts as, after having been tested and found naturally free-growing and prolific, we may desire in future to grow on some warm wall.

About this latter portion of the subject I shall have a few suggestions to offer to my brother amateurs, chiefly because it constitutes my best experience. It is now about ten years since, having carefully studied the cordon system on the continent under Dubreuil, and tried it on the open wall in various ways, I adapted it, with the important modification of the summer pruning-in of the shoots, to the exigencies of the orchard-house. After some years' further trial the system (chiefly represented by diagonal cordons), being successful, the results were published in 1860 in a small work. Since that period in a certain number of orchard-houses in this island and in England the system has been adopted for the back walls. Among these none have been so successfully worked as the well-built house at Grange Lodge, in this island, under the able management of Mr. Pethers. On the diagonal cordons of the back wall this season were grown some of the very finest possible fruit. Two other houses on this plan in the island show remarkable signs of fruit for next year. But this is not the place to allude to this matter further than as far as it bears on the point mentioned above—namely, the removal of trees to the open wall, which, I contend, is greatly facilitated by the adoption of these flat diagonal cordons.

Readers of this journal may remember a part of the orchard-house controversy, where one excellent authority predicts the universal adoption of the system for Pears. I have myself no doubt on this subject, having for ten years very successfully grown Peaches, Pears, Plums, Cherries, and Apples side by side in this way, as is well known. Nay, I believe that the very choicest fruit can best be grown in this fashion. I should suggest, then, to my brother amateurs that, if they wish to thin out their stock of trees in their houses, planting them out against a good warm wall would be easy in this way. If they had cordon trees trained as mine are, diagonally, at intervals of 3 feet against the back wall, nothing would be easier than to plant them against an open south wall in the same fashion. Care only would be required that foreright shoots, which in doors bear well away from the wall, should not be allowed to grow too far out, if in the open air, simply because they thus lose the warmth of the wall. A skilful gardener, however, would avoid this error; and I have seen this year two thousand Peaches grown in a friend's garden on trees trained in a similar manner. As to other fruits, especially Pears, they bear wonderfully as diagonal cordons. On one of our south walls (about 12 feet high), are seen Plums, Cherries, and Pears growing side by side. We can begin our wall with a May Cherry, and end it with a winter Pear. Apples of the best kinds are splendid in this fashion, though not equal to

those grown in an orchard-house. This year in these islands Apples have done well under glass. But to return to the point. I mean that any one desirous of thinning out his orchard-house would be best enabled to do so if he grew his trees in this shape, so that if he chose they might be removed to the open wall, for it is evident that a bush tree is unfit to be planted against a wall. It requires to be cut down and much altered, besides losing a year's fruit. Some trees there are which do better; but generally, if the tree be a fine open bush, well-rounded and equal, as it should be, it is then very ill adapted for a wall tree.

The next best shape to the flat diagonal is the vertical cordon, which shape is common enough in nurseries now. By cutting away one side of this vertical tree it can be adapted for a wall. If so, plant it as a diagonal cordon at an angle of 45°, if in a bearing state, free growing, and healthy; but if exhausted by bearing, or weak, or a maiden tree, then plant it at an angle of 75° till it lay hold of the soil, and begin to thrive; then lower it to 45°. It thus assumes the natural angle of most branches; Nature points this out, and experience demonstrates that this angle is the most proper to produce fruit. A vertical branch is apt to grow too strongly, and the sap to accumulate at the upper portions, leaving the lower ones gradually bare. If brought down to the horizontal line the vertical shoots will absorb the sap, and become unduly strong, while the extremities of the leaders will dwindle away.

I confess to being quite a bigot in favour of these diagonal cordon trees. They are easy to manage, do not grow rampant as some think, they cover the wall very soon, you can have a great variety of sorts, they come sooner into bearing, any particular tree is easy to protect, being grown in such a small space they require no lifting, nor root-pruning; even in the house, as far as I can see, if dissatisfied with the tree it is easy to remove it, and there is no unpleasant blank space left on your best walls for years; and as to fertility, there is nothing to compare with it, space for space. Any further suggestions required I shall be happy to communicate; but it seems simple enough.

At present few Peaches remain in the house, only three sorts in all; but this is an error to be remedied. Thomas's Late, an American, is only about 8 inches round as yet, and colouring well. It is a delicious late Peach, in shape like Early York, and well worthy of trial in lean-to houses against the wall. The next to ripen, at the end of the month, will be Tardive d'Espagne. This Peach it is very difficult to ripen well in the south unless the season be favourable. When thoroughly well grown in the house it looks like a waxy Peach, and is continually taken for such if exhibited. This is one of the triumphs of the house. These yellow Peaches, though not so valuable for the market, if early (so the dealers say), when late become then very useful. For dessert they are very fine, their colour by contrast with other fruits makes them very telling. Baldwin's Late, is only half grown at present. Being in a pot, and not in a very good place, it has not a good chance to colour well. There are seven Peaches on the bush, and these are not to be ripe till November. By that time most of the leaves of the other trees will be fallen. These three varieties are good sorts. Out of doors they would be simply ridiculous failures.

We have planted early Potatoes between the potted trees, and in the spare borders. Not requiring the house for wintering anything, nor for Chrysanthemums, nor finding anything, except early Potatoes and Strawberries, worth the trouble of growing, we have always planted Potatoes in this way—not that it adds to the beauty of the house in winter; quite the contrary, but these are valuable things to produce.

As to the sorts planted. Early Handsworth is really a very good sort for these houses or for frames; it is large, and can thus be dug up comparatively early, and the haulm is naturally short, which is a very valuable quality for Potatoes under glass. Planted on the 1st of October, we dug up some weighing six to the pound, which were ready by the 25th of March, and realised 15d. per pound then. Carter's Early Champion Kidneys are also a good sort to plant, because early Kidney Potatoes always realise more when sold for some reason or other. We have this year planted both sorts, and also some French varieties common here. It is best, however, not to look too long at our houses

from the money-point of view. A comparison of all our garden books would be very amusing, not to say instructive.—T. COLLINGS BRÉHAUT, Richmond House, Guernsey.

TRITOMA UVARIA.

RESPONDING to Mr. Robson's request in the last issue of your Journal, I beg to state that *Tritoma uvaria*, though always exceedingly fine, was never so magnificent as this season in East Lothian. We have here several long back lines of it, which have been truly magnificent for a long time, and still continue so. It presents no signs of degeneracy, but the reverse, and most certainly we have no hardy herbaceous plant that can compete with it from the beginning of September till the middle of October. After the latter date *T. grandis* takes its place, and flowers in great beauty up till Christmas; so that by planting the two kinds plant for plant in the rows, the flowering season of the *Tritoma* can be extended for four months. *Grandis* is much more vigorous, and throws up its flower-stems much higher than *uvaria*.

They are here moulded up before severe frost sets in like a row of Potatoes, and we never lose a plant; and when the flower borders, to which they form a backing, are dug or trenched, a quantity of leaf mould is worked in near the roots of the *Tritoma*, and in this way it thrives amazingly. The soil is a very dry, deep sandy loam, and this is one of the driest districts in Great Britain, so that it cannot be superabundant moisture that makes it thrive here. Like most other flower-garden plants, it requires liberal treatment. Long may it be ere we have to lament the loss or degeneracy of so noble a plant.—D. THOMSON, Archerfield.

VISITS TO GARDENS PUBLIC AND PRIVATE.

MESSRS. FRANCIS AND ARTHUR DICKSON & SONS,
CHESTER.

ON my return from a mournful journey to Ireland, such a journey as one can take but once in a lifetime, I found myself one morning in the ancient and loyal city of Chester. Many, many years ago I had passed through it ere railways ran, and when the journey from London to Dublin occupied some two or three days instead of eleven hours as now; but so peculiar is the character of the city, and so vivid are the impressions that are made in early days, that it seemed all quite familiar ground, and but as if the other day that I had seen it. Having a few hours in the morning to spare before the train for London started, and having those with me who were like myself interested in such matters, instead of lionising the town we determined on visiting the nurseries of the Messrs. Dickson, about which we had heard a good deal, and of which the good people of Chester seemed to be not a little proud as a good specimen of a provincial establishment; and the extent of the grounds and the order and neatness that prevailed throughout fully justified them in the opinion they had formed.

These nurseries are situated at Upton, about a mile and a half from the city, and are in an elevated position, exposed to a good deal of rough weather, so that plants obtained from thence and removed to more sheltered districts would be likely to thrive very well; for it is a great point to have such trees and shrubs as have been used to a rougher climate than that in which they are permanently to abide, while the reverse is oftentimes injurious to the well-being of the plants, such as have been reared and nurtured in sheltered and warm districts being very apt to suffer on their removal to colder ones. There are upwards of 130 acres comprised within the limits of the ground, the soil about one-half good retentive loam, the other half light sandy soil; and although this might seem unsuitable to many other things which are grown, yet by judicious management everything is in a healthy and vigorous condition. There is a long range of houses containing the usual varied stock of a general nursery in both stove and greenhouse plants. I have never seen, for instance, a healthier and, for its size, a finer stock of Azaleas than those which are grown here. No symptoms of thrips could I see on any of the plants; and many of them were of that attractive style

known as half-specimens naturally grown, and all well set with bloom-buds. The outside wall of these houses is planted with *Berberis Darwinii*, which is one of the prettiest of our shrubs, always fresh and green, and when in flower presenting a perfect mass of beautiful apricot-coloured racemes, and pretty also in fruiting time, with its large plum-coloured berries. In front of the houses there is a long narrow slip laid out somewhat in Nesfield's style of gardening. Coloured panels, however, are not used, white being the only covering of the walks, the bright colouring of the flowers being regarded as sufficient for the purpose. Amongst the many combinations here, I think that a bed, the centre of which was composed of *Centaurea candidissima*, and the edge *Amaranthus melancholicus ruber*, was one of the most effective. This plant has not, however, succeeded very well so far north, the climate seems too cold for it. *Gazania splendens* makes a fine autumn bed, and at that season of the year seems here to remain open in the sunshine instead of closing up as it does in the summer. On one of the walls I noticed a fine plant of *Clematis lanuginosa* in good flower; as also *C. lanuginosa candida*, a pale nearly white flower, which will contrast well with those new ones of Messrs. Jackman of Woking, so rich and brilliant in their colouring.

As Roses are now so much in vogue, and have become everybody's flower, and as persons will not now care to buy inferior sorts, the Messrs. Dickson have devoted a large space to their culture. As fine and healthy a selection of Roses in pots as I have ever seen, numbering 20,000, and a large portion of those on their own roots, afford a tempting selection to the Rose-growers of Cheshire, and indeed of other parts too; while from thirty to forty thousand standards in the ground are also such as an amateur would well like to select from. A new rosarium in a sheltered position has also been lately planted, and in it I observed in bloom many of the best and finest varieties of Hybrid Perpetual, Bourbon, and Tea Roses. Charles Lefebvre to its other charms seems to have added this of its being very free-flowering in autumn. *Géant des Batailles*, *Celine Forestier*, *Maréchal Vaillant*, and others were also displaying their beauties, and the vigour of their foliage seemed to indicate that they were well contented with their situation. I was told that the Messrs. Dickson had more than once been exhibitors at the shows of the Royal Horticultural Society of Dublin, and that they had been successful.

Conifers seem also to thrive here remarkably well, although we are sometimes apt to associate them with the peaty soil of Surrey; but nothing could be healthier than those here cultivated. There was one specimen of *Araucaria imbricata*, the most beautiful and unique that I have ever seen; for there are evidently several varieties of this noble tree, this having a far more drooping and graceful habit than any that I have seen, while the foliage was large and vigorous. *Wellingtonia* seemed also quite at home, a fine tree eight years old being upwards of 12 feet high, and with a very large stem. Then there were nice specimens of *Thuja compacta*, *japonica*, *Lobbiana*; *Picea amabilis*, *P. Nordmanniana*, &c. Rhododendrons were also in good health.

The portion of the ground allotted to fruit trees is very large; and everything here, as may be supposed, is done on a very large scale. Thus, for example, there were seed-beds of the common Laurel which contained upwards of 12,000,000 plants, this being arrived at by taking a square foot, counting the number of seedlings in it, and multiplying the whole space by that. Nor have I seen anywhere more vigorous Vines in pots than there are here. Again I must ask, What becomes of them all? It can only be, I think, that they are grown for a season in pots by purchasers, and then killed by injudicious management. I know of no other way to account for the immense quantities that are everywhere grown, and for which there ever seems to be an increasing demand.

Perhaps one of the prettiest things in the whole grounds was a ribbon-border of Hollies, which when completed will be a quarter of a mile in length. The edge of the border is composed of two rows of Box; then some variegated Ivies are pegged down; and then five rows of Hollies, first yellow variegated, then white ditto, then yellow, then white, while the background is composed of the more ornamental species of green Hollies. I cannot conceive that anything in its way can exceed this when the whole mass has been filled in,

while it will have the great advantage of being always bright and clean. As forming part of ornamental grounds it is well worthy of imitation by those whose tastes are not circumscribed by the extent of their grounds or the depth of their purses; and I should be glad to see this same border in a few years' time, when it has filled in, as I believe it will.

Amongst minor matters I noticed a very excellent contrivance for vases. It is well known that stone vases are very expensive, and iron ones are not so seemly; but here the plan is adopted of converting iron into stone—that is, the iron vases are painted a light stone colour, and when wet are dredged all over with sand. This adhering to the wet paint gives the exact appearance of stone, and can be of course easily renewed from time to time.

It will be seen that these nurseries fully deserve the character they have obtained of being amongst the most extensive and best arranged of our great provincial establishments. There was great order and neatness arrived at throughout, and this is not an easy matter in such an establishment; but it certainly enhances very much the appearance of the grounds. The morning on which I saw them was bright and clear after the bounteous rains of the past few weeks; and I came away most favourably impressed with the entire management and stock of this extensive concern. I should add that at the shop in Eastgate Street there was a very fine selection of the best and most sought for Dutch bulbs of all kinds, a worthy appendage to the Upton grounds.—D., *Deal.*

COTTAGES, AND HOW TO TENANT THEM.

SOME friends have kindly told me that I was rather hard on the proprietors of cottage property who had taken little thought about a water supply, and have brought forward instances with which I was well acquainted previously of unsatisfactory investments in cottage property, and the next to impossibility of keeping these cottages, when let at a very cheap rent, even in a healthy condition from overcrowding, and the want of all refined habits in the inmates. I have been told of instances where proprietors had spent a lifetime in endeavouring to give a cheerful aspect and a high moral tone to villagers on their estates; and that they failed in all their attempts because the people would either crowd their houses by taking people to live with them, or when a son and a daughter at a very early age—but in the painful circumstances none too early—thought proper to marry, without anything to commence housekeeping with, they received an asylum with one of the parents, and thus two or three families were crowded together into a place only suitable for one, with all the consequent attendants of pestilence and fever, increase of poor rates, pauperism, &c.; and the question is put, What would you do under such circumstances?

Well, in the first place, if a gentleman had a number of cottages so bad as to be unfit to live in comfortably, and there could in general seasons be no water supply for the promotion of cleanliness, it would be best to give the occupants due notice, and either correct what was amiss or pull the cottages down.

Secondly. If a gentleman, as most gentlemen do, let nice cottages at a lower rent than mere contractors, one specification as to overcrowding should be rigidly enforced, and no families, or even lodgers, allowed to live there without the knowledge and permission of the proprietor or his agent. If this is not done I know what the consequence will be. Where no refined or high moral feeling exists, a house that might do for a man and his wife, and perhaps four children, will soon be made to hold as it can some ten or a dozen, and of different sexes, and anything like morals and decency be swept away. The very knowledge of such supervision will be a great help to refinement and morals.

Thirdly. In all such cases monthly tenancies, or at least monthly notices, are of great value; and if the breaking of the conditions be followed with a few cases of expulsion, these will be of great benefit. It is within my knowledge, that in cases where every convenience for decency and cleanliness was given, the tenants would persist in having a dungheap and a slop-hole close to their dwelling instead of at the farthest part of their gardens, careless how they produced the seeds

of fever and pestilence in themselves and others. It is a great blessing that the law will not permit a man to poison himself with malaria, or be the means of polluting the atmosphere of his neighbours; but the most effectual law with all such people when admonition and repeated warnings are of no avail, is simply the notice that they must quit their quarters. A few instances of this kind in a neighbourhood will do a vast amount of good.

Fourth. Though I am anything but a Malthusian, I have a strong impression that in many agricultural districts lads and lasses marry too young; and I consider that they always do so when they have nothing between them to commence housekeeping with. As for true love in such cases, it is all a chimera. If a young man loved a woman he would never ask her to join her fate with his until he could place her in a cottage at least ordinarily supplied with the necessaries of comfort and decency. I shall never forget going into the cottage of a newly married pair, both very young, and seeing a few rough boards in a corner for a bed, a board with four round spreading sticks stuck in as legs for a table, a couple of large stones and a board between them for a seat, and a pot to answer all culinary purposes. This might be an extreme case, and was; but how many young couples commence life with taking on their first month's housekeeping, and trying to pay the old as they take on the new? Now, were I a squire, or a gentleman, or nobleman, and felt a little pride in my cottages, I would allow no young couple to take possession of them without showing me that they could furnish them respectably by their own honest earnings and savings. The gentleman who will condescend to do this, or insists on his agent doing it, will take one sure step towards securing good, well-behaved, moral tenants—a step which will be more productive of good than lots of mere routine visitations once or twice a-year, or ever so many sermons on cleanliness or propriety, however earnest and rightminded the clergyman or the minister may be.

What gentleman would think of letting a farm to a man merely because he was the highest bidder, if it were well known that he had no effects and not a pound at his banker's? And yet gentlemen complain of the unthrift, the untidiness, the want of decency, and absence of moral feeling too perceptible among a few of their cottage tenantry, notwithstanding all necessary arrangements to the contrary, though they give some of their best cottages unhesitatingly to young couples who between them can scarcely defray the expenses of the marriage feast and marriage ceremony, and commence their united career in debt to the butcher, baker, and grocer, and even to the cabinet-maker for the stool on which they sit and the bed on which they rest—a debt that too often clings like a millstone round their necks, paralysing all the energies of a life. Proverbs are fine things in their way, often the concentrated wisdom of ages; "Marry for love and work for money," however, has ruined thousands. The landlord who would feel a satisfaction not only in having healthy commodious cottages on his demesne, but in having them occupied by industrious, moral, well-conducted families, will exercise the truest benevolence in ascertaining that the young aspirants for tenancy have been well-conducted, and acted on the obverse of the proverb, and worked for money before they married for love. Ah! when scarcity and want stalk in by the door, and ugly wretchedness looks in at the window, love, happiness, and industry are apt to go out by the chimney. Some people that will be reached by nothing else than their own self-interest must have that appealed to; and the scrutiny I propose would tell on the best interests of all connected, and by means of example exert a general beneficial influence. With every desire that charity may perform its perfect work, it requires no seer's vision to perceive that many of our social evils in the country as respects the working classes, are owing to an undue patronising of the necessarily-ever-needy, because the inconsiderate, the unsteady, and the unthrifthy. Though not so pleasant, it would be well to try the other course.—R. FISH.

ORCHIDACEOUS PLANTS.—The ninth Part, just published, of "Select Orchidaceous Plants," edited by Mr. Warner and Mr. Williams, fully equals its predecessors in useful informa-

tion and beauty of illustration. The four Orchids described and portraited are *Anguloa Clowesii*, *Chysis Limminghii*, *Ceologyne cristata*, and *Disa grandiflora superba*. The portrait of the last-named is one of the most successful we know, and does justice to this splendid flower; for, as the authors truly say, "Disa grandiflora superba ranks among the finest of greenhouse Orchids." They add, "Our drawing was taken from a very strong plant that produced with us eight blooms on one spike—an unusual number, for commonly not more than two, three, or four are produced. It was grown in a greenhouse under Vines, but as near the glass as possible, where it obtained plenty of light."

ERECTING AN ORCHARD-HOUSE.

I HAVE been particularly interested with the communications in the Journal on orchard-houses, their management, &c., and purpose building one, dimensions not yet determined on; but before commencing to build, would you give me your advice on one or two matters? First. Let me tell you I shall have to manage it myself, I cannot afford to employ a man regularly. You will understand from this economy is a great consideration. As to the description of house—is Sir Joseph Paxton's method of building greenhouses a patent? Should I be infringing his rights, or lay myself open to any pains or penalties, if I bought wood and employed a country carpenter to work it up on his (Sir Joseph's) principle?

Which is the better plan—to grow Peaches and Nectarines, &c., in pots, or to plant them out? If grown in pots would soil to the depth of 2 or 3 feet require removing, and a certain amount of rubble put in, and what thickness? If this turning out of soil and bringing the rubble could be dispensed with, I think it would save a great expense. If grown in pots would the trees require repotting every year, or how often, and how many years do you suppose a tree could be grown in a pot? Will the trees produce as much or more fruit when grown in pots as when planted out, or vice versa? and why do people always write and talk of growing trees in pots—is there some great advantage in it? Nearly all the articles in your Journal and your little manual on greenhouses, speak of this method as if planting out was not to be thought of.—TRENT.

[We do not take the responsibility of determining what is, and what is not a patent; but we feel pretty certain that if resolved to adopt Sir Joseph Paxton's method of houses for the million, a village blacksmith cannot make them up so economically as they are advertised, as all the work is cut by machinery, and put together by men used to it. If economy is your object, and the place is your own, a fixed roof will be the cheapest and best. In Sir Joseph's system, to which you refer, sashes are made in the usual way; but there is a raised cap between every two sashes some 8 to 12 inches wide, glazed, and this by means of a lever is raised to its full width, or for as little as half an inch. By means of nuts the lever might raise a third, a half, or the whole of the length of this ventilating cap.

We would rather you decided yourself as to whether you would grow in pots, or plant out the trees. You will find the matter temperately stated in "Doings of the Last Week," and in a late short article by "R. F." Both systems have their advantages and disadvantages. The pot system enables you to have more variety in little room, gives you more command over the size of your plants, and enables you to do all the root-pruning required very easily, and will give you good fruit if you thin sufficiently; but the plants will require much more attention, and especially in the way of watering. The fruit may be as numerous as you like, but unless well thinned they will not be so fine as from trees planted out. On the other hand, trees planted out are apt to grow too luxuriant, and will demand root-pruning as well as frequent pinching of the shoots, but you will be more independent of the water pail and continued attention. In your case, absent during the day, and with little help, if great variety were not your object, your simplest and best plan would be to plant the trees and train to a trellis 15 inches from the glass, and cultivate temporary plants in pots until the permanent trees filled the house, and then if you give air early in the morning the trees would pretty well look after them.

selves. The pot system must have labour and frequent waterings.

If you decide on pots, you have no occasion to have a rubble-bottomed border. A little fresh soil beneath the bottom of the pots will be quite sufficient, and half or three-parts plunging the pots will be advisable, chiefly for saving watering and keeping the roots in a more equable condition as respects temperature.

If grown in pots, and the pots are from 15 inches and larger in diameter, the trees will do well for several years in the same pots with the help of fresh top-dressings every year. We have seen trees in 20-inch pots that had borne well for ten years, and showed no signs of falling off. Smaller-sized pots would be better to be shifted, and that should be done as soon as the fruit is gathered. For instance: a small tree in a ten-inch pot should get one from 12 to 15 inches in diameter.

If you tell us what sort of house you resolve on, and what is the mode of growth you decide upon, and want more definite information, we shall be glad to help to the utmost of our ability, as we fully sympathise with all circumstanced like yourself. We must not forget that one charm of the pot system is that the trees will afford you nice exercise in pinching and watering night and morning. If you would rather escape these pleasures, then plant out and train to a trellis.]

WHITE PERPETUAL ROSES.

THE request of a correspondent (J. Broughton), to know what are the best white and light-coloured varieties of Hybrid Perpetual Roses of the present and past few years, induces me to say a word on the point. There is no doubt that this is a direction in which the skill and energies of hybridisers ought to be exerted, for it is a class in which we are very deficient. There are times when Madame Vidot and Mrs. Rivers, especially the latter, appear nearly white, and then they are most beautiful; but why have we had nothing approaching that style for some years? The run has been all on the crimson and roses, and even the latter have been comparatively little thought of when darker and brighter flowers were to be had; and however much we may admire the bright and gorgeous colouring of this style of flower, we still want something of a lighter character for contrast, and hence are obliged to go to the Teas and Noisettes for them; indeed, those white flowers which have been produced during the past few years can hardly be called Hybrid Perpetuals, the character of their growth and style of flower alike proclaim them to be Hybrid Noisettes. The best of them, however, I still conceive to be Mdlle. Bonnaire and Virginal; but perhaps I shall best satisfy your correspondent's wishes by giving descriptions of each of them as they occur to me.

Mademoiselle Bonnaire (1861).—Pale flesh, nearly white, and in bud most exquisite. One of the prettiest of the class. Wood very green and thorny. A good grower, though not robust.

Virginal (1860).—Very similar to the above, although, perhaps, not quite so full, and more white—i.e., with less of the flesh tint in it; flowers of a fair size. Blooms exhibited by Messrs. Paul & Son and Mr. Keynes might be even called large.

Louise Darzins (1862).—Quite white, but small. Habit of plant very dwarf, and altogether with very much of the Noisette character in it. Blooms profusely.

Mademoiselle Eugénie Verdier (1861).—Nearly white, with pale flesh centre in the style of Virginal. I have seen some very beautiful blooms of it. The habit of the plant is moderately vigorous.

Madame Alfred de Rougemont (1863).—This I saw exhibited very well early in this year. It is not a pure white, but slightly shaded with rose; may prove an acquisition.

Madame Freeman (1863).—Pale flesh, changing to white. I have not seen enough of this, but it seems to be delicate.

Sœur des Anges (1863).—Large, pale blush, but very much inclined to crack and come defective, so that I fear it will never be of much service.

Louise Damaisin (1864).—This I have not seen, but it is described as a virgin white.

Of these I should be contented with Mademoiselle Bonnaire, Virginal, and Madame Alfred de Rougemont.

As to "light" Roses I hardly know what your correspondent wishes; but I hope some day soon to give a list of Roses with descriptive notes, which may be some guide to amateurs; for this I am endeavouring to collect materials, and am sure that the widespread interest in the Rose will make it, even though imperfect, acceptable to many. I should add that amongst light-coloured Roses—that is, those of a very pale shade of rose and pink, nothing more beautiful than Louise Margotin and Emotion has been produced; but then they are Bourbons and not Hybrid Perpetuals, and if your correspondent does not think this an insuperable objection, he will find that these two flowers will give him at times perfect gems, and, like all the Bourbons, particularly in the autumn.—D., Deal.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

THLADIANTHA DUBIA (Doubtful Thladiantha).—*Nat. ord.*, Cucurbitaceæ. *Linn.*, Dicecia Pentandria. Native of northern China, and seemingly of the Sikkim Himalaya, at from 5000 to 6000 feet elevation. It is a graceful climber with yellow flowers, certainly hardy enough for out-of-door cultivation in the south of England, and how far north requires and deserves proving.—(*Bot. Mag.*, t. 5469.)

DENDROBIM NODATUM (Knotted-stemmed Dendrobium).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Moulmein. Introduced by Messrs. Low & Co., Clapton Nursery. Flowers creamy white and orange.—(*Ibid.*, t. 5470.)

CYANOTIS NODIFLORA (Nodose-flowered Cyanotis).—*Nat. ord.*, Commelinaceæ. *Linn.*, Hexandria Monogynia. Native of South Africa. Flowers dark lilac. "It is a ready flowerer, blooming during June in an ordinary greenhouse."—(*Ibid.*, t. 5471.)

VITIS BAINESII (Baines's Gouty Vine).—*Nat. ord.*, Ampelidæ. *Linn.*, Tetrandra Monogynia. Native of tropical Western Africa. It has a very gouty stem, resembling, indeed, a large bulb, with very succulent, leafy branches. Flowers green, inconspicuous, in a warm stove during July.—(*Ibid.*, t. 5472.)

AMPHIBLEMMA CYMOSUM (Cymose Amphiblemma).—*Nat. ord.*, Melastomaceæ. *Linn.*, Decandria Monogynia. Tropical African plant. Flowers bright lilac. Stove plant.—(*Ibid.*, t. 5473.)

LINUM MACRAEI (Macrae's Linum).—*Nat. ord.*, Linaceæ. *Linn.*, Pentandria Pentagynia. Sent from Lata, in Chili, under the name of *Linum Chamissonis*, by Mr. Pearce, collector for the Messrs. Veitch, but previously found by Mr. Macrae, at Valparaiso, and named after him. Flowers orange, blooming in July.—(*Ibid.*, t. 5474.)

ROSE—King's Ace, raised by Mr. Cranston, the nurseryman, of King's Ace, Hereford. Flowers bright crimson, and extra large and fine.—(*Floral Magazine*, pl. 213.)

LINUM CHAMISSONIS.—See above, *Linum Macraei*.—(*Ibid.*, pl. 214.)

CLEMATIS RUBRO-VIOLACEA.—Raised by Mr. G. Jackman, jun., of Woking Nursery, from seed produced by *C. lanuginosa* hybridised by *C. viticella*. Flowers 4 to 5 inches in diameter, rich reddish violet, perfectly hardy; blooms from July to the autumn.—(*Ibid.*, pl. 215.)

PELARGONIUMS.—British Scilors, "of the Diadem class, but having a more distinct spot, the colour being a lively purplish-crimson, with good white throat." John Hoyle, of the class technically known as "painted flowers," upper petals deep maroon, with carmine edge; lower petals pinkish scarlet, veined and painted with dark crimson. Both raised by G. W. Hoyle, Esq., Reading.—(*Ibid.*, pl. 216.)

TEICHINIUM MANGLESI.—This really handsome amaranthaceous plant has been raised from Swan River seeds by Mr. W. Thompson, of Ipswich, and from specimens grown by that gentleman our figure has been derived. Very little is as yet known of its habits, but it is amongst half-hardy annuals that it will probably find its place in our gardens, even though it be naturally, as some other of our Australian so-called annuals are, of more extended duration. The plant forms at first a tuft of radical leaves, which are long-stalked and oblong-spathulate in form, smooth, and of a deep green colour. From among these arise the flowering stems, to the height of 1½ foot; they are furnished sparingly

below with lance-shaped sessile leaves, become slightly branched, and each branch terminates in a crowded oblong-oval spike, which consists of scarious rosy-coloured bracts, from amongst which issue the rosy purple flowers, these protruding considerably beyond the bracts. Both bracts and flowers are clothed with long conspicuous hairs. "Few more lovely plants," observes Sir W. Hooker, "have been introduced to our gardens than this, which is one of the most striking of some fifty species known to botanists;" and this encomium we think our figure will be found to justify. Mr. Thompson, who fortunately got a few of his imported seeds to vegetate, describes the root as being apparently perennial, throwing up several branched stems, each branch bearing one of the handsome heads of flowers. The copious white hairs, so characteristic of the genus, with which the florets and bracts are clothed, give, he remarks, a singular aspect to the plant, and contrast effectively with the Amaranth-purple petals. Under the lens these hairs are pretty objects; owing to their denticulations the germination of the seed, moreover, revealed a peculiarity worthy of note. The plumule, instead of rising from between the two unequal seed-leaves as in most plants, was found to be emitted from a point considerably below them. The same thing occurs, he adds, in *Dodecatheon meadia*. *Trichinium Manglesii* was first described by Dr. Lindley some twenty years since in the "Botanical Register," where it is spoken of as a most beautiful plant, with the heads of flowers 3 inches across. It has not till now, however, found its way into our gardens.—(*Florist and Pomologist*, iii., 217.)

DWARF FRUIT TREES.

I DESIRE to plant some dwarf standard Pear trees, and am anxious that as little shadow as possible should be thrown over my borders. I should feel obliged, therefore, if you would inform me whether such trees can be kept at a height of 5 or 6 feet and bear a crop. Should I have them on the quince stock? and how should the ground be prepared for their reception? Also, I should be glad if you could let me know what sorts would be most suitable to our Yorkshire climate (near Doncaster), and on a limestone soil? I think of putting in twelve trees. I presume they should be procured from some nurseryman in my own neighbourhood, as if brought from the south they might find this climate too bleak.—YORKSHIRE.

[We would not have them on the quince stock on your dry limestone subsoil. You can keep them dwarf by lifting or root-pruning annually in the autumn. The soil will require no preparation, but the roots should be carefully spread out in planting, so as to be about 6 inches below the surface, and we would mulch the surface during summer. It is of no importance whether you purchase your trees from a nursery in the south or north of England. The following is a list extracted from Mr. Rivers's "Miniature Fruit Garden," and we shall take this opportunity to publish what he says in the same useful and interesting little work about bush Apple trees:—

"The following varieties are well adapted for bush culture, as they are spreading in their growth and difficult to form into compact pyramids, although they may be made into spreading and prolific conical trees. It ought, however, to be mentioned, that those sorts—such as Louise Bonne of Jersey, which form handsome pyramids, make very pretty compact bushes by cutting out the central branch to within 3 feet of the ground; so that pyramids may be easily formed into bushes. I may add that these bush Pears produce the very finest fruit from their being so near the heat and moisture-giving surface of the earth."

"In situations near the sea-coast exposed to 'sea breezes,' small fruit gardens may be formed by enclosing a square piece of ground with a beech hedge or wooden fence, and planting it with bush trees. A piece of ground 500 square feet will be large enough to cultivate thirty trees at 4 feet apart in it, or twenty-five trees at 5 feet apart. Many a seaside cottage may thus have its fruit garden."

List of Pears Adapted for Bush Culture.—Alexandre Bivort, January; Joséphine de Malines, March; Marie Louise, October; Winter Nelis, December; Beurré d'Amanlis, September; Beurré de Rance, March; Beurré Diel, December;

Beurré Giffard, August; Beurré Goubault, September; Doyenné Boussoch, October; Jargonelle, August; Conseiller de la Cour, November; Dr. Troussau, December; Zéphirin Grégoire, January; Nouveau Poiteau, November; Jalouse de Fontenay, August; Catillac (for baking), December; Léon le Clerc de Laval (for baking), March.

"Apples as Bushes for Market Gardens."—Our market gardeners, as a rule, are very deficient in their knowledge of fruit-tree culture, and they have much to learn. The usual practice with them is to plant standard or half-standard trees in rows, some 20 or 30 feet apart, and between them Gooseberry and Currant trees. The ground is dug between the trees in spring deeply, and often carelessly. Nothing can be more barbarous, for the ground is so shaded that no surface roots can have the benefit of air and the heat of the sun; and if by any chance they could come to the surface, they are, as a matter of course, destroyed by the spade. It is true that in some of the rich market gardens near London large quantities of fruit are grown in spite of the uncoutch treatment the trees receive, but this does not alter the case.

In a well-ordered fruit garden every kind of fruit should have its department, and instead of seeing, as in Kent, a row of trees of all sorts, mixed in the most heterogeneous manner, no mixture of species should be allowed; every kind should have its allotment—Apples on the Paradise stock, ditto on the crab stock; Pears on the quince stock, the same on the pear stock; Morello Cherries as pyramids on the Mahaleb stock—the best of all methods for their culture—and the various kinds of Duke Cherries on the same stock; Heart and Bigareau Cherries on the common cherry stock; Plums as bushes, pyramids, or half-standards, should all be separated, and not planted higgledy-piggledy, as they have been and are now. The

sound-headed market gardener will, when his mind is turned to improved fruit-tree culture, see all this, and make his fruit garden a pattern of order.

"I have been led into these remarks on market garden fruit-tree culture by my own experience, and especially into a consideration of the great improvement that may be made in the culture of Apples on the English Paradise stock. These trees will this season, the third of their growth in their present quarters, and the fourth of their age, give an average of a quarter of a peck from each tree, so that we might have, from 4840 trees, growing on one acre of ground, 302 bushels of fine Apples, which, even this abundant season (1864), would be (if Cox's Orange), worth 5s. per bushel, or £75. In 1866, the trees then averaging half a peck each, would double this sum, and make an acre of Apple trees a very agreeable and eligible investment. The kinds likely to sell best in the markets, and which are most productive, are the following:—Cox's Orange Pippin, Reinette Van Mons, Ribston Pippin, Sturmer Pippin, Scarlet Nonpareil, and Dutch Mignonette. These are dessert Apples. The following are valuable kitchen Apples, and abundant bearers:—Hawthornden, New Haworthden, Small's Admirable, Cox's Pomona, Keswick Codlin, Dumelow's Seedling, Lord Suffield, Norfolk Bearer, Duchess of Oldenburgh, and Forge Apple. Such large varieties as Bedfordshire Foundling, Blenheim Orange, and Warner's King, should have

more space, and be planted 4 feet apart, and be thinned out by removal, as recommended for those planted 3 feet apart. I refer the reader to pp. 53, 54 for the proper method of planting these bush Apple trees, which is exactly that recommended for bush Pear trees on quince stocks.

"It may be by some made a question of expense, for although the return must be large and profitable, the purchase of nearly 5000 Apple trees would involve a large outlay. To this I reply—first, that stocks costing only a small sum per thousand may be planted and grafted where the trees are to grow permanently; and, second, that a large demand, which my method of planting would create, will also create a cheap supply. The preparation of the ground should be as follows:—It should, previous to planting, be forked over to a depth of 20 inches; if very poor and exhausted, from 30 to 40 tons of manure may be forked in—not more, as trees such as I have recommended—viz., Pears on the quince stock, and Apples on the English Paradise stock, do not root deeply—this ought to cost £6 13s. 4d. The annual expenses are forking the surface in spring, £1 6s. 8d., and hoeing the ground—say four times during the summer, £1 4s. I give the amounts paid here for such work. Then comes the summer-pinching of the shoots by a light-fingered active youth, and this may at a guess be put down at £1, making the aggregate annual expenses £3 10s. 8d., or say under £4. The

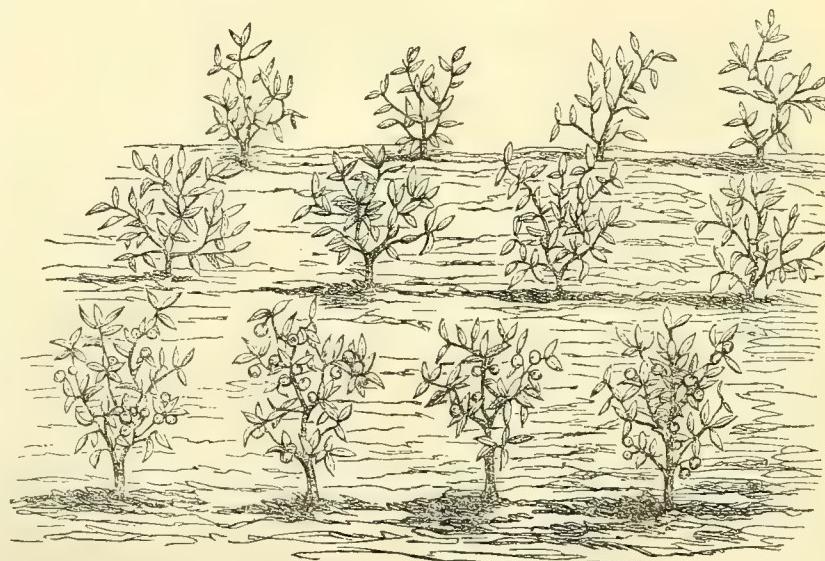

large return will amply afford this outlay, even adding, as we ought to do, the interest on capital and rent.

"It will be seen that what I propose is in reality a nursery orchard, which may be made to furnish fruit and trees for a considerable number of years. To fully comprehend this, we must suppose a rood of ground planted, as I have described, with 1210 bush Apple trees. In the course of eight or ten years half of these, or 605,

may be removed to a fresh plantation, in which they may be planted 6 feet apart; they will at once occupy half an acre of ground. At the end of sixteen or eighteen years, every alternate row of trees in the first plantation, the rood, will require to be removed, which will give 302 trees to be planted 6 feet apart, leaving 303 in the original rood. The 1210 trees will by this time occupy one acre of ground at 6 feet apart. With proper summer-pruning or pinching they will not require any further change, but continue to grow and bear fruit as long as they are properly cultivated. The great advantage reaped by the planter is the constant productiveness of his trees; from the second year after planting they will be always 'paying their way.'

"The unprejudiced fruit-cultivator will quickly find out the great advantage of my mode of Apple and Pear cultivation.

"In the usual old-fashioned mode, standard Apple trees are planted in orchards at 20 feet apart, or 108 trees to the acre. If the soil be good, and the trees properly planted, and the planter a healthy middle-aged man, he may hope at the end of his threescore and ten, to see his trees commencing to bear, and may die with the reflection that he has left a valuable orchard as a legacy to his children, but has not had much enjoyment of it during his life. Now, although, like most fathers, I have a strong wish to benefit my children, I hold the idea that one ought also to think of one's own

gratification; and so I plant trees, and recommend the planting of them, that will give me some satisfaction, yet leave a 'remanet' for my children.

"A French pomologist who paid me a visit last year, said—'Ah! now I find an Englishman planting for himself as well as for his children,' and went on to say that he was struck by seeing in England so many standard trees in market gardens, the planters of which could have derived but small benefit from them; and the apparent ignorance of fruit gardening as a lucrative occupation. This he, in fact, imputed to our climate, which, Frenchman-like, he thought totally unfit for fruit culture in the open air, yet felt much surprised to see here the produce of a well-cultivated English fruit garden, in a climate not nearly so favourable as the valley of the Thames.

"I have only to add that, besides my plantation of Cox's Orange Pippin, I have another of upwards of 400 trees, which has now been in existence upwards of ten years, so that I am not theorising, but deducing facts from a sound basis."

The reader is referred in the preceding page to directions given in pages 53 and 54 of Mr. Rivers's book for planting and managing bush Pear trees; we therefore give one more extract to render this novel mode of culture fully intelligible.

"The plantation should be a sort of nursery, and for this purpose the trees should be planted 3 feet apart row from row, and 3 feet apart in the rows. A piece of ground planted after this method will contain 4840 trees per imperial acre. The trees may be suffered to remain at the above distance from each other unroot-pruned and unremoved for seven, eight, or ten years; and then, as they will nearly touch each other, every alternate tree should be removed and another plantation formed. The removal of the trees should be done carefully, so that those left will stand 4½ feet apart, and in quincunx order, thus— . This may be done as follows:

"Presuming the first row to consist of ten trees, begin at the first row by removing the 1st, 3rd, 5th, 7th, and 9th trees; in the second row remove the 2nd, 4th, 6th, 8th, and 10th; in the third row again the 1st, 3rd, 5th, 7th, and 9th trees, and so on with all, and through all the rows however long. At this distance they may remain for sixteen, eighteen, or twenty years. At the end of one of these periods every alternate row of trees must be removed, leaving the permanent trees 6 feet apart. The periods of removal must to a certain extent depend upon the nature of the soil; if this is of high fertility the removal of the trees must be commenced at the earlier period."

Mr. Rivers depends upon rigid summer pinching of the young shoots, which he finds retards the rapid growth of the trees, forms them into compact round bushes, and brings on remarkable fertility.]

CULTIVATION OF THE MELON.

(Continued from page 274.)

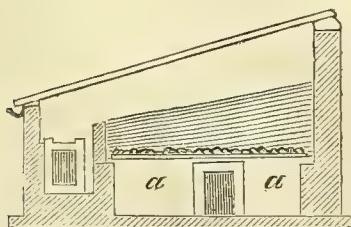

Fig. 14.

Fig. 14 is a pit to which bottom and top heat is supplied by flues, one in front for top heat, and another under the bed in a chamber, *a a*. The flue passes along the centre of the bed first, and returns along the front. The chamber is covered with flagstones, on which is placed a little rubble, and then soil to the thickness of 1 foot. The plants may

either run over the bed, or be trained to a trellis fixed 9 inches from the glass

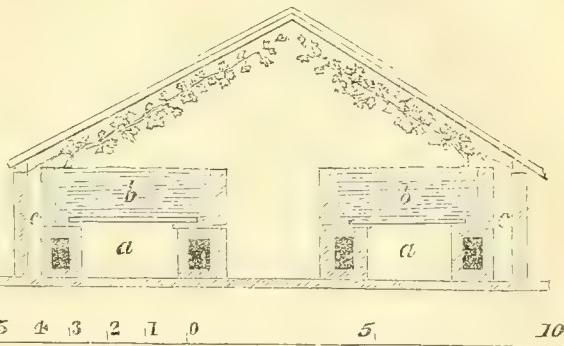

Fig. 15.

Fig. 15 is a section of a span-roofed house heated by flues. The flues are made to furnish both top and bottom heat, and between them are chambers, *a a*, which communicate bottom heat to the beds, *b b*. The flues are partly under the beds, to which they communicate heat by the spaces left between the flagstones and the sides of the beds, as well as by the chambers, *a a*; whilst top heat is afforded by the sides of the two centre flues, and the heated air ascending from the openings, *c c*.

Besides the houses already described, there are many others differing only in being modifications of them; but I shall pass over these, only giving another plan by which Melons can be grown for the million.—G. ABBEY.

(To be continued.)

MADAME VAUCHER, CLOTH OF GOLD, AND GOLDEN CHAIN GERANIUMS.

WITH reference to the communication of your correspondent, "J. P. M.", regarding the flower of Madame Vaucher Geranium, and others, changing colour, I myself noticed it in Madame Vaucher, the others I do not possess. In the late dry weather the flowers were almost as pink as Trentham Rose, but as nearly like those of Madame Chardine as possible; even now (and we have had plenty of rain) I can perceive no material difference in them. Madame Vaucher is certainly a little lighter, but it would not be distinguished from the other by a casual observer. With regard to the Cloth of Gold and Golden Chain Geraniums, they have been growing here side by side this summer, the Golden Chain making scarcely any progress, while Cloth of Gold is very luxuriant, and I think that in the damp climate of the north of Ireland it will speedily take the place of Golden Chain. I may add that bog mould is freely used at bedding-out time.—G. COUET, *The Gardens, Crom Castle*.

PRUNING THE SHOOTS OF ORCHARD-HOUSE TREES.

I HAVE this season followed the directions in Mr. Rivers's book, "The Orchard-House," with great success so far, but having ceased to pinch in the trees at the end of July, as he directs, I now find them full of shoots a foot long, and I know not how to treat them. I see in your Number of the 27th ult. your Guernsey correspondent speaks of the present as the time for pruning, and in the "Doings of the Last Week" your Journal speaks of cutting the roots which have penetrated through the pots. Mr. Rivers directs this to be done later: I am, therefore, anxious to know both what pruning I must do as to the long shoots grown in August, and where I must prune, either shoots or roots.

I must add my own testimony to the success of an orchard-house as far as one year's experience allows me to do so. Nothing can be more satisfactory. My Peaches have been large, some weighing nearly 6 ozs., and perfect in flavour. My Nectarines, also, were first-rate.—C. P.

[You may shorten the shoots now, but we would rather

defer it later, so that you could more clearly discern a young leaf-bud—a shoot-bud to cut back to, as it is undesirable to cut to a fruit or fruit-buds. There will be little difficulty as to the short difference of time in the root-cutting, as referred to in "Doings of the Last Week," and the work of Mr. Rivers. In the former case it was judged expedient to lessen growth and hasten maturation, and, therefore, the pots were lifted up, and what roots were outside were cut away. There were so few of them, that the pots being well watered the plants scarcely flinched a bit. Very likely if the bright weather had been foreseen the operation might have been delayed a week or two; as it is, the appearance of the trees is all that could be wished. As soon as you like you may stump back the long shoots made in August, but cut to a wood-bud. If scarce of wood behind, such young wood would bear after such an autumn as this; but if you have enough of wood behind, little or none of the August-made will be wanted. It has encouraged root-action, and the presence of the shoots will cause your buds to break stronger next season if other things are properly attended to, as we feel certain they will be from your account of your success. But for keeping the trees or bushes compact, and the fruit-spurs near home, many growers allow a little wood as you have done, as it makes the tree stronger on the whole than close continued pinching.]

BRYN-Y-NEUADD.

THIS, the residence of John Platt, Esq., is situated near the seashore, and not far from Llanfairfechan railway station on the London and North-Western Railway, seven miles from the city of Bangor and the same distance from Conway.

After a week's ramble through some of the most interesting parts of North Wales, exploring the beauties of mountain and ocean scenery, I came unexpectedly upon this princely place. The house, a very neat and rather extensive structure, in the Gothic-Italian style of architecture, is backed by the fine mountain scenery of Caragfawr and Penmaenmawr, and from its situation near the coast has a very imposing appearance.

A few minutes' walk from the railway station, along the right of which is a wall bounding part of the domain, with the park, brought me to the principal garden-entrance, near which is situated the head-gardener's cottage, a good substantial structure, and built in harmony with the other buildings in the place. On making application at the cottage I was informed that Mr. Eastwood was in the garden, and thither I at once made my way, and introduced myself as one of the fraternity, asking the favour of a look through the grounds, &c. This brother of the spade at once acceded to my request, and with that amount of courtesy and good humour, which ought to distinguish every one connected with so interesting an occupation, showed me the whole of the garden establishment.

The kitchen garden and forcing-houses are in extent and character quite in keeping with the magnificence of the place: some idea may be formed from the fact that there is 270 feet of lean-to hothouses fitted up very completely, and in which was a mixed collection of fruit and flowering plants.

The first house I entered in this range was a Peach-house, the crop from which had been gathered, and the trees were in remarkably fine health, with fine foliage and well-ripened wood. The fruiting and succession Pines, which occupy a portion of this range, are in fine health, and promise successful results.

In one of the tropical houses in this range was a magnificent collection of ornamental-foliaged plants. The following I noticed as being remarkably fine—viz., Croton variegata, Croton picta, Dracaena ferrea versicolor, Begonia Rex and its varieties, Cyanophyllum magnificum, Cissus discolor, Coleus Verschaffeltii, Caladium bicolor splendens, Pandanus javanicus variegatus; and besides these, there were many others too numerous to mention.

At the end of this range of houses a door leads through the back wall to a Fern-house, which is arranged so as to produce an artistic effect. The back wall and ends of this house are studded with a variety of rustic materials, into

which, at suitable places, are introduced plants of this interesting family.

In addition to the range of houses just described there are four span-roofed houses on the Paxtonian principle, each 105 feet long and of various widths. They range north and south in front of the principal lean-to range, and are occupied with a variety of fruits. Conspicuous amongst them is a Black Hamburg-house, in which the Vines are remarkably strong, and with well-ripened wood, bearing large well-shouldered and finely-coloured bunches. The Muscat-house in this range is a picture of splendid fruit and foliage. Considering the short lapse of time since the Vines in these two houses were planted, which I understood did not exceed two years, they surpass anything I have previously seen for luxuriance and healthy strength. The Peach and Nectarine trees in the houses are evidently quite at home; they are particularly clean and vigorous, with short-jointed and well-ripened wood. I was informed by Mr. Eastwood that they had produced a heavy crop. I noticed, also, some fine Peach and Nectarine trees in pots for early work looking promising, also some strong good-shaped Pear trees in pots, affording fine examples of what can be done with good management in this mode of culture.

The whole of the extensive range of houses is heated on the one-boiler principle, the necessary precaution having been taken to introduce a second boiler in case of accident to the one in use.

There are four acres of kitchen garden in two divisions, the walls being furnished with suitable trained trees, and the quarters for vegetable culture are systematically arranged. The names of the various kinds are neatly painted on wood tallies—a feature which should not be lost sight of in kitchen as well as in flower-garden culture.

I had almost forgotten to mention that there is a complete range of sheds at the back of the principal range of hothouses, and the bothy for the young men. I could not help noticing this necessary appendage from its elevated position—a feature very often lost sight of in the construction of young men's rooms, but of which so much has been previously written that by some it may be thought unnecessary to name it here.

I observed a nice lot of strong promising Strawberry plants in pots prepared for forcing; also collections of Cinerarias, Primulas, Azaleas, Camellias, &c., being slightly accelerated for conservatory decoration during the winter months.

The flower garden and dressed grounds are laid out so as to harmonise with the style of the mansion, and are in extent about five acres. Bedding plants to the number of 25,000 have this season been planted out. A very neat geometric flower garden on gravel is arranged on the drawing-room side of the mansion, at the termination of which is a neat ornamental span-roofed conservatory 120 feet long by 15 feet wide, which was gay with a variety of well-grown plants. In the grounds is a rustic summer-house happily arranged, and commanding fine and extensive views of the opposite coast scenery; from this point with a single glance of the eye can be seen the whole line of coast stretching from the point near Penmon, along the shores of Beaumaris and Garth Point, near to the Menai Bridge and Bangor, when, by a slight turn of the head, the eye rests on the beautiful richly-wooded scenery of Penrynn Park and Castle, the varied and extensive domain of Colonel the Hon. E. G. Douglas Pennant, M.P., the proprietor of the far-famed Penrynn slate quarries. I shall not soon forget the delight with which I gazed on the rugged mountain scenery in this immediate locality, blending as it does with the softening touch of dressed grounds, and the whole on a magnificent scale. The lawn and pleasure grounds at Bryn-y-Neuadd are for the most part laid out in the picturesquesque style. The whole, having been recently formed and planted, has not the effect at present that it will ultimately produce when some of the many Conifers and other specimen trees and shrubs shall have attained a moderate size. This fine place, so delightful in its landscape and pleasure ground scenery, is managed by the indefatigable gardener Mr. Eastwood, with the assistance of ten men; and, aided by his worthy employer, I have no doubt that he will succeed in making this place and its productions rank high in the horticulture of Wales.—JOHN GOULD, Rose Cottage, Redditch.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The decline of the late crops of Peas, Beans, Cauliflowers, &c., should be followed by their immediate removal, and no decaying or useless vegetable should at this moment be allowed to cumber the ground. If the vacant spaces be not immediately required, they had better be rough dug or ridged, for exposure to the ameliorating influence of frost and thaw. The distribution of manure should be governed by a due consideration of the late and future crops. For instance, the Onion quarter has probably received manure sufficient to carry a crop of Cabbage without further assistance. Strong-growing Peas and Beans impoverish the land; quarters which have been thus occupied might be appropriated to early Potatoes in due season. Asparagus, the stems should be removed, and an adequate quantity of seed collected for the yearly sowing. The out-door Cucumber-bed, stirred over, will be suitable for August-sown Cauliflowers, which will require the protection of hand-glasses. Some prefer keeping their Cauliflower plants in small pots under glass. Lettuce, a good supply of the late sowings should be planted in situations best calculated to afford them protection in the winter. When the accommodation of pits or frames can be afforded a quantity might be planted within them to insure a regular supply, independent of the weather. Remove the leaves from Rhubarb and Sea-kale intended for forcing, and keep a look-out for slugs and weeds.

FRUIT GARDEN.

The principal routine here will consist in gathering and storing all the late varieties of Pears and Apples. The present is the best time for lifting and transplanting very vigorous unfruitful trees on the walls. Apricots, Peaches and Nectarines, Pears, Plums, &c., may be so treated with great advantage, and after the operation is completed they should be well mulched up for the winter. Fill up all the vacancies on the walls with young trees, never let this be left undone till spring, if it can possibly be avoided. Where root-pruning is considered necessary, now is the time to see to it.

FLOWER GARDEN.

Scarlet Geraniums, Fuchsias, &c., which it may be intended to winter for use next season, to be taken up immediately and placed in safe quarters. Variegated Geraniums will not bear much frost, and where the plants have to be wintered in situations which are not very suitable for them, they should be taken up before they are injured, as they will be much more liable to damp off, and die back in winter, if the wood is at all touched by frost. They should not be cut back, but be kept over the winter just as they are lifted from the beds. Cut them back early in spring after starting them into growth, when the cuttings will root very freely in heat. The autumn-rooted stock of Verbenas, &c., must be well attended to, keeping them perfectly clear of green fly, and exposing them freely to air on every favourable opportunity, so as to prevent anything like growth after this season, and to keep the plants hard, in which state they will be much less liable to fog off under confinement for a week or two in winter, than if they were kept in a soft growing state until overtaken by severe weather. Except where alterations are in hand, the principal work in this department for the present will be mowing and clearing up, and if anything like neatness is to be maintained, sweeping up leaves will soon require daily attention; also, see to getting gravel walks thoroughly cleared of weeds and moss; roll them frequently when wet to keep the surface hard and smooth. Steps should also be taken to fill up the beds as they are cleared, for the purpose of contributing to the enjoyment of spring. A miscellaneous mixture of dwarf early-blooming shrubs, perennial plants, Wallflowers, &c., and bulbs are most commonly planted.

STOVE.

Pursue a kindly course of treatment with the Euphorbias, Gesneras, and such things for winter-flowering, these will soon be of great service. A temperature of from 65° to 70° by day, and 60° by night will suffice, still maintaining a somewhat moist atmosphere in the afternoon and during the night, with a free circulation of air, keeping also a quiet

ventilation all night. As some of the Orchids become ripe, such as the Catesetum family, the Cycnoches, Lycastes, &c., they may be removed to a drier, and somewhat cooler atmosphere. The Phaius grandifolius, with the Stenorhynchus speciosus will soon begin to blossom, also Cypripedium insigne and venustum. Let them have plenty of heat and moisture.

GREENHOUSE AND CONSERVATORY.

Whatever watering may be necessary in the conservatory should be done early in the day, so as to allow of the superfluous moisture being dried up before night, for there is much more danger from damp among plants in flower at this season, than from a rather low temperature; and on cold, dull, cloudy days it will be advisable to use a little fire heat, with air during the day, so as to secure a moderately dry state of the atmosphere before night. Use fire heat very sparingly, however, and only when it may be necessary to prevent injury from damp, or to prevent the temperature falling below 40°. Hyacinths and other Dutch bulbs, if not already purchased, should be procured and potted without delay. Summer-flowering twiners which usually become unsightly by this time, should be cut back rather freely. Shade can now well be dispensed with, therefore not a spray that can be spared should be left to obstruct the light. Let Azaleas be tied into form as soon as it can be done, in order to give a neat appearance. Look carefully after red spider on Bossiaeas, Chorozemas, and anything else liable to that pest. Red spider is destroyed by laying the affected plant on its side and well washing the under sides of the leaves with the engine, applying the water with as much force as the foliage will bear. Let Cyclamens, Lachenalias, Oxalis, Centradenias, tree Violets, and such little winter favourites, be kept on a warm front or end shelf entirely unshaded. Let pot specimens in bloom be frequently rearranged, so as to make the most of them, for the finest specimens become too familiar to be interesting when allowed to remain too long in one place.

PITS AND FRAMES.

Regulate the general bedding stock, and get the majority established in small pots. Give as much air as possible, and restrict the supplies of water to mature the growth as far as possible. All temporary pits for their accommodation should be completed by this time, and glazing and other repairs forthwith finished. Common mats afford scarcely sufficient protection to the half-hardy plants in store pots; for such purposes a stock of straw or reed mats should be made in wet weather.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE weather is threatening to be again as dry as ever, with frosty nights, bright sun, and keen east winds. So long as the dryness continues we shall suffer but little from frost. Part of the Carrot and Beet should be taken up when nice and dry. Hunted after grubs that had begun on our Lettuces, Endive, and young Cabbages. Go where we will, and meet whom we will, the grubs are the prevailing cry. In our neighbourhood it has made some fields of Turnips that looked well in the end of July a desert. When withered, just like our Cabbages, there would be one or two of these fat leathery grubs at every root. Gas water, or a little gas tar sprinkled over the land, is a good thing for keeping them away. When once there, there is little remedy except constantly looking after them whenever a plant flags. We have sprinkled a little tar between our rows of Cabbages from a straw brush, and we imagine it has helped to keep the grub from the plants; and in the ground so sprinkled the plants do not suffer. Soot, lime, ashes, &c., which do some good against slugs, snails, and worms, are quite ineffectual against the grub. "Catch and kill is the only cure," and the smell of gas tar the best preventive against the fly mothers, or daddy longlegs of some sort, inserting their eggs. In digging or trenching for Cabbages, &c., a little gas water or gas tar sprinkled on the soil as the work proceeds, will also cause those not killed to bolt from such quarters. The craneflies or daddy longlegs will soon be found on covered colonnades, fences, &c., and sometimes we have swept a peck in a morning from a stone pavement.

These are quite innocent of themselves, but we must lessen the number if we would be free from leathery grubs.

Caterpillars.—Just so with the beautiful whitish-coloured butterfly so plentiful in the kitchen garden in summer. They do no harm; but the caterpillars that come from their eggs would soon clear a quarter of Cabbage, and make the finest Cauliflower unfit for the table. We caught great numbers of these butterflies this season, but that has not caused us to be free from caterpillars. Fortunately so far, the daddy longlegs tribe are almost helpless early in the morning, and can do little in the way of escape. Unfortunately, however, the grub preys beneath the surface, whilst the caterpillar in its feeding state is more easily seen. In the case of young plants a dusting of powdered lime and soot will generally dislodge if not quite kill them. In the case of large plants forming hearts it is best to pick them off. A quick-handed boy, with a vessel with quicklime in it so shaken as to cover the caterpillar, would pick off some scores in the time he would run down a butterfly. Where such things become ravaging pests instead of interesting curiosities, boys may well be employed at hunting the butterfern and picking off the caterpillars.

Celery.—Gave the beds a good soaking with sewage water for the last time, and, the ground being so dry, we were tempted to give the whole rather more than a half earthring-up; and will soon follow in the mode previously referred to, as, after this month, unless the weather is excessively dry, there will be little danger of excessive dryness at the roots.

Cauliflower.—Planted out young plants under hand-lights on banks facing the south, in the mode lately detailed. Placed two or three leaves over Cauliflowers fit for use, in case either the bright sun or a little frost might injure it. In such weather the great extremes of heat and cold are apt to give the heads a tanny-like appearance. Examined these heads for slugs and caterpillars. A few cold nights will help to settle the latter. Watered the crops coming on, and proceeded with hoeing, digging, and attending to other things much the same as in previous weeks.

FRUIT GARDEN.

Went over the second growth from Apples and Pears on low standards; likewise thinned and stopped a little Currents and Gooseberries. As the season for planting is advancing, we would advise all having small gardens to grow.

Gooseberries and Currents on strained wire trellises. These, well nipped-in, will soon be full of fruit-buds, will bear immensely in little room, and will be easily protected from birds, &c. A singular fact came to our knowledge this season—that Currents and Gooseberries that were cleared by wasps, when grown in the usual bush form, escaped being touched when grown on the upright trellis near at hand. This, we fear, however, might be only a striking coincidence. We think the wire and trellis had been tarred, and, though we detected nothing, the wasps might have found something distasteful to their sense of smell. In this neighbourhood it would not be advisable to plant, however, until moist weather, as the ground is very dry—drier than ever we have known it, and water is again getting scarce.

Strawberries.—Cleaned amongst the rows of beds and slightly surface-stirred. Would have liked to water as some fine plants are flagging again. Lifted the pots intended for forcing to prevent the roots going even into a hard gravelled bottom, so as to arrest growth. Picked off all weeds and runners, and for the second time gave the plants more room by setting the pots further apart that every leaf may receive the full benefit of the sun and air. We have given manure water when it was required. We will let little more rain water soak them, but will turn the pots on their sides when rain comes. We will do this shortly with Black Prince, and the earliest small pots of Keens', to fit them for forcing by a period of rest, and in a week or so will place the pots on their sides on the north side of a fence.

Orchard-house.—Watered the trees in pots at all suffering from the drought. Gathered the most of the Plums, and some fine specimens of Apples and Pears from very small pots. Swept off a few of the leaves that were getting the

right autumn tint, and when we can find time, and a damp cloudy day comes, we will smoke them densely with bruised laurel leaves, not allowing any flare of flame however. A little precaution now may save much trouble afterwards. This simple smoking has been intended since the bulk of the fruit was gathered, but has not yet been carried into execution. Most likely will use some Capsicums with the laurel leaves, and the mixture will do no harm to anything except any insects that may be alive.

Peach-house.—Swept off the greater part of the leaves, and gave more air now, as the dry heat from the sun—of which we took advantage to harden and consolidate the wood—if continued, would be apt to make the fruit-buds start. We observe some three or four starting at the top of the house. We see little use in general for taking the glass off such houses, unless they be very early; and even in that case, if the wood was early matured, the trees would be rested more under the glass, with shade, than when fully exposed to the sun without glass. No shading will be needed unless for early houses.

Vineries.—Went over these, removing any berry getting mouldy, of which there were very few; and also taking away the most of the laterals, to give more light to the house, and also to concentrate more strength in the wood left for next season. Those who wish for Grapes in March must now have the houses shut up, and be getting the Vines to start slowly. Those who wish them ripe in the beginning of May should have the pruning done and the cleaning effected, and put gentle fires on by the end of the month. When Lady Downes', West's St. Peter's, and even Muscats, keep until March, there is less occasion for having Grapes at the beginning of the year, though to have them always shows good and careful gardening. In houses now full of Grapes ripe and ripening, air should be left on all night, unless in frosty weather; and, during these very sunny days, a little water may be sprinkled with a syringe over the floor, border, or stage in the house—not at all enough to damp the house, but just enough to moisten the atmosphere a little, to prevent anything like drying or shrivelling.

Pinery.—The Pines should now be made secure for the winter. When grown in pots and in tan-beds, &c., fresh material should be supplied for bottom heat. In general it will be safest not to plunge the pots much more than halfway, and to stir the bed and add fresh tan on the surface as the bed cools. The plants dislike much moving, and especially great and sudden changes of temperature, even though they by no means show it so much as plants with thinner leaves. A broken leaf it should be collected never heals, and hence in beds well heated by hot water beneath, and where fine, fibry, turf soil can be obtained that does not easily run together, and through which water passes freely, the best method of growing is turning the plants out, and during the growing season supplying them liberally with manure water at the suitable temperature. Some of our best growers keep only the young plants in pots, and plant out whenever they become nice stubby plants. If the right fibry soil is obtained, it matters however but little whether the plants are grown in pots or in the bed; but in the latter case the leaves are less easily or less likely to be injured. Such fibry turf as we refer to should be brown instead of dark, should be covered with grass (not with broad leaves, but with foliage like needles for smallness and hardness), should hang together like felt rather than be loose, from the small number of roots, and the short distance they run; and should smell sweet as a nut instead of sour after it has lain in a heap for a few months. The roots will not only run rapidly and be of large size in this material, but clear manure waterings will pass easily through it. A little lime in such water will keep worms, &c., at bay.

Figs.—Gathered most of those out of doors. Obtained some fine fruit from some in pots, removed from orchard-house into a pit, where they could be kept closer and warmer. Gathered freely from second crop in the small Fig-house, and cut away a good deal of young fruit that was not likely to ripen this season. The cutting off such fruit within an eighth of an inch or so of the stem is much better than tearing or rubbing them off, as the cut-scar healing over, young Figs will often come from the sides of the cut part,

and though they hardly show, or remain small during the winter, they will do good service next season. This thinning of redundant fruit that will not ripen, and the removal of wood not wanted, cannot be too quickly done in the case of trees intended to be forced early next season. One cause why the first crop of Figs of some sorts is apt to fall, is the heavy crop of young useless fruit that often hangs on the trees in the autumn.

Melons, where still deemed a matter of importance, must now be kept warm, and any moisture they require be given chiefly at the roots, without wetting the surface soil, unless the atmosphere is heated by hot-water pipes, so that plenty of air might accompany the heat. Where, as here, the fruit is now at a discount, the space will be better applied for storing plants of many kinds, as bedding plants, &c.

ORNAMENTAL DEPARTMENT.

Stove Plants.—Many Orchids, as Stanhopeas, now require less water; but in these cold nights fires will require to be used. Such winter-flowering plants as Thrysacanthus ruticans, Poinsettia pulcherrima, Euphorbia jacquinæflora, and late lots of Gesnera zebra, will be greatly benefited by having a little bottom heat, and being kept for a few weeks in a rather warm moist atmosphere. A slight change to dryness will cause the flowers to come freely. Justicias, Ruellias, &c., will require less attention and less heat to bring the flowers out in perfection. As little fire as possible should as yet be used, and advantage taken of the fine sunny weather to harden wood and ripen buds. Where houses have been shaded for the season with whitening, or anything of that kind, it would be well to lessen the shade as soon as, or even before, this bright weather changes.

Hardwooded Greenhouse Plants, especially the more tender of them, should now be placed under glass, but with plenty of air given to them, until the nights are colder. The same care must soon be bestowed on Azaleas and Camellias in pots. Many plants are much injured by having their roots greatly cooled at this season. For plants growing in the natural soil the temperature at the roots will be more equable than in the case of plants grown in pots, as the soil will not be so hot as the atmosphere in a hot day; but in such weather as we have lately had the roots will be much warmer than the head and branches during these clear cold nights. We just reverse the case with the generality of plants in pots now—the tops become sun-baked during the day, and the roots are ice-baked at night. If pots were set hollow to secure drainage, and were then partly or wholly plunged, the plants would enjoy many of the advantages of planting out, and escape some of the evils, such as over-luxuriance, involved often by growing a tree or plant turned out in rich suitable soil. Meanwhile, when we know how hot an exposed pot becomes during the day, and how cold it becomes by radiation and evaporation during the night, we must take some precautions against such evils; and one of the simplest will be to water when wanted, chiefly in the morning, so that the soil in the pots may become dryish before night.

Pelargoniums.—Had these mostly potted, or at least placed under cover. Potted, also, a second batch of Cinerarias and Primulas, Mimulus, &c. Now is a good time to prune and dress Roses intended for early flowers, and a little bottom heat and a rather moist but airy atmosphere will suit them better than any fire heat as yet to the atmosphere of the place. Cinerarias and Calceolarias can scarcely be kept too airy, moist, and cool, if frost be excluded. Give them heat of any kind, and whole hosts of insects will attack the plants as a reward for the extra nursing.

Bulbs.—All intended for Christmas and onwards should now be potted. Equal parts of sound sweet loam, old cow-dung well sweetened, and half a part of leaf mould and sharp sand will grow Hyacinths, Tulips, Jonquils, Narcissus, &c., in first-rate condition. The pots when filled should be set in a shady place, or if placed out of doors should be covered for 6 inches with old tan, ashes, leaf mould, sand, cinder ashes, &c., and no forcing should be attempted until the pots are filled with roots and the flower-stalks pushing. Bulbs intended for the flower garden (now still beautiful from its summer ornaments), should be placed on a dry hard bottom in any shady sheltered place—Hyacinths 5 inches apart, Tulips 2 or 3 inches apart, Crocus 2 inches apart—and then

be covered over with 3 inches of fine rich leaf mould and rough loam. These bulb-beds may so remain until the flower-beds are cleared, well dug, and prepared, and then the bulbs may be lifted with little balls, and scarcely suffer from planting.

Rolled, swept, and cleaned lawn round flower-beds, still very fair. Proceeded with putting in more cuttings of bedding plants, and removed many struck to more open positions.

Old plants of *Scarlet Geraniums* take up much room in winter, so that unless for particular purposes, young plants from cuttings now and a short time previously, will generally be as satisfactory as older plants, which must have more room in winter. No weather could be better for hardening-off all things struck under glass or protection of some kind; but though these should have all the sun possible, or that they are able to bear, they must be kept cool and airy at night, but free from all danger from frost. Plenty of air after sunset, and as much light and comparative closeness during the day as the cuttings will stand without flinching, are the secrets for the successful striking of all plants, and especially those of the bedding kinds.

Preparations should now be made for taking up the more tender or rarer bedding plants—as Golden Chain, Mrs. Pollock, and Cloth of Gold; and for inserting the Calceolaria cuttings in a week or two. For most things young plants will be found the best for uniform beds, older plants are useful for high rows, pyramids, &c.

Florists' plants, as Carnations, Picotees, Auriculas, and Polyanthus, should be cleaned and placed under glass, well tilted back and front, night and day, chiefly that heavy rains may be thrown off, but of this there is little appearance, though they may come suddenly.—R. F.

COVENT GARDEN MARKET.—OCTOBER 8.

Foreign Hamburg and Portugal Grapes continue to arrive, and of home-grown fruit the supply is plentiful and good. Of Pines there is a moderate supply; Peaches and Nectarines are nearly over. In out-door fruit and vegetables we have nothing fresh to report.

TRADE CATALOGUES RECEIVED.

Robert Parker, Exotic Nursery, Tooting, Surrey.—Catalogue of Stove, Greenhouse, and Hardy Plants, Hyacinths, and other Bulbous Roots. 1864-5.

William Paul, Paul's Nurseries and Seed Warehouse, Waltham Cross.—Rose Catalogue, 1864-5; Descriptive Catalogue of Hardy Ornamental Trees and Shrubs; List of Beaton's Hybrid Bedding Geraniums.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

LADY DOWNES' VINES (*F. B. L.*).—The large leaf belongs to a true Lady Downes' Vine; but after a careful comparison with several Vines of that variety the small leaves appear to belong to quite another sort, they being differently lobed and rounder.

HEATING BY GAS.—Will "S. J. H." who described the apparatus he employs, oblige us by informing A. Maples, Esq., Spalding, Lincolnshire, where the apparatus can be purchased?

AMARYLLIDS (*James Curdley, Adelaide*).—The Amaryllids you refer to can be supplied at from three to five guineas a dozen. Mr. Anderson asks us to refer you to Mr. Williams, Paradise Nursery, Holloway.

BOWLING GREEN PATCHY (*E. Tweedy*).—Leave it until the spring. Early in March sift over it a sufficiency of fresh, moderately fertile earth to barely cover the grass, say half an inch in depth; then sow over the half acre 2 lbs. of Suckling seed (*Trifolium minus*), and roll it in with a light roller. No raking is needed, except to make the earth sifted on level before sowing.

SOIL AND TEMPERATURE FOR PLANTS (*A. W. A.*).—*Aristolochia cymbifera* requires a compost of equal parts of turfy peat, turfy loam, and leaf mould, with a free admixture of silver sand. It is a stove plant, doing well when subjected to ordinary stove management. *Pasteostonia crenata* we do not know. *Philadelphia mexicana* is hardy, and will grow in any soil, lightish loam being preferable.

WORMS IN POTS (*Ruby*).—We have repeatedly stated how to expel them from pots. Mix 14 lbs. of lime with thirty gallons of water, stir well, and forty-eight hours afterwards flood the pots with the clear liquid, having previously stopped the holes with clay or cork. The worms will come to the surface, when they are easily destroyed. After an hour or two let the drainage act. If this is not effectual repeat the dose. To make a bottom impervious to worms, mix boiling coal tar with ashes, form a floor 4 inches thick, lay an inch of small gravel on the surface, and ram firm. Another way is to place a layer of lime riddlings an inch thick, ram firm, add two more layers, and then sufficient coal ashes for ploughing purposes. To prevent worms coming from the outside have edgings of boards 3 inches above the surface, and paint them with boiling gas tar. We will answer for them not troubling you afterwards if you take care not to place whole families in the pots along with the compost. There are plants with white flowers named *Ageratum latifolium*, *A. angustifolium*, *A. album*, and *A. conspicuum*, the last two of which come true from seed. Any seedsman can supply seed; but we believe the first two cannot be had from seed, it not being obtainable.

MUSHROOM-BED IN FRAME (*W. M. Newland*).—You made your bed all right, but you should have waited until it had heated, and ascertained the degree of heat before spawning. As it is you have spawned it, and the heat may probably be too much for the spawn. Whether it will heat or not depends of course on the thickness of the dung, and as to that you leave us in ignorance. It was wrong to place the spawn on the surface and cover it with soil. It should have been covered with an inch of droppings, and then with soil. You have done wrong again to water the bed, for moisture at this early stage tends to prevent the spawn running, dryness being essential for that. As you have made the bed and spawned it, we would advise you to wait for about six weeks and see what the result will be. You may water lightly a month hence, but give none until then, and afterwards cover the surface with an inch or two of hay or dry litter. The soil at this season in an unheated place will not require much, if any watering.

PREPARING ROSE-BEDS (*A Twelve-years Subscriber*).—In the first place it will be necessary to dig the beds out to a depth of 2 feet and remove the subsoil, laying the surface soil on one side, for it will do to mix with the new soil, which may consist of turfy loam, neither strong nor light, two-thirds, leaf mould one-third, 6 inches of well rotted manure being worked in at the time of planting. If the ground is well drained no stones will be needed at the bottom of the beds, nor are they of any value unless there be drains to take the water from them, for digging holes and placing rubble at the bottom is only making drains without outlets. If the ground is drained, 6 inches of brickbats or broken stones at the bottom of each bed will be serviceable. On this place a layer of turves, grass side downwards, and after mixing the old surface soil with the new compost lay it in the trench, and do not tread it more than can be helped. This done, put on 6 inches of well rotted manure, and fork it neatly into the soil. The beds should be made at once, and rather above the level of the surrounding surface, to allow for the soil settling before the Roses are planted in the beginning of November. The Roses planted five years should be taken up carefully, and the old long roots pruned to about one-half their length, but the fibres and small roots should not be cut, except to remove injured parts. Closer pruning than usual will be necessary, and it should be deferred until March. Dwarf Roses planted at the foot of standards will, to a certain extent, hide the bare stems; but if these are considered unsightly why not plant dwarfs only? No Roses will do well under the heads of standards, and they cannot be grown to perfection when their roots are intruded upon by other plants. It is best to grow one thing in a place and have it good.

SEEDING GERANIUMS (*W. I. W.*).—Send specimens in flower to the Floral Committee of the Royal Horticultural Society. If the Committee commend them you can then offer them to some of our leading florists.

OLD COTTON CAKE AS A MANURE (*J. G. S.*).—We presume that you mean the refuse after the oil has been expressed from the Cotton seed. Like all other vegetable refuse, it is useful as a manure. We should spread it over the surface just previously to the last digging or ploughing before inserting the crop. It would benefit pasture land sown thinly on the surface early in the spring.

UPAS TREE (*An Old Subscriber*).—It is the *Antiaris toxicaria* of botanists, and is included in the natural order Urticæ, and Polygamia *Dicea* of Linnaeus. It is a native of Java, Macassar, and Borneo, and is a tree having an abundant milky juice; it attains a height of 90 or more feet; leaves not unlike those of some of the *Magnoliæ* in substance and pale green colour, but slightly heart-shaped, and the sides not quite equal in size. In Hogg's "Vegetable Kingdom" it is stated that according to the analysis of Pelletier and Caventon, Upas antaria contains an elastic resin having the appearance of caoutchouc, but differing in its qualities; a gummy matter; and a bitter substance, soluble in water and alcohol, in which resides the deleterious properties of the juice, and which appears to contain a new vegetable alkali. Strychnine has never been discovered in it. This poison leaves no trace behind it in the bodies of the animals that have died by its action; the blood-vessels are only filled with a blackish blood, as in asphyxia. Introduced into the veins, death is even far more rapid than when applied by a wound; eight drops injected into the jugular of a horse killed him in a minute and a half in a tetanic state. The flesh of animals killed by this poison may be eaten with impunity. So virulent does this tree appear to be, that even linen made from its fibre, insufficiently prepared, is so acrid as to cause the most distressing itching. But though thus virulent, the statements that it is death-stranght to rest under its shade are superlative exaggerations. There was, and probably is now, a large specimen in the Botanic Garden at Calcutta, and we have been under its shade, handled its bark, and gathered leaves from it with impunity.

FLOWER GARDEN PLAZ (*A. W., Woolley Park*).—The Editors never supply plans; they only criticise those submitted to them. In "Flower Gardening for the Many," which can be had free by post from our office for five postage stamps, there are several plans and how to plant them; and a great number of other plans are distributed through previous volumes of this Journal.

MILLET'S MIGNONNE PEACH (*A Dartford Reader*).—It is the same as the Royal George, a very good Peach, and thrives well in a Peach-house.

FRUIT TREES FOR NEW ZEALAND (*B. Wells, Woolwich*).—A letter was forwarded to you on this subject, and is returned by the post office, marked "Not known in Woolwich." Send us a stamped envelope with your full address.

HYDROPLINT (*An Old Subscriber*).—We believe that it is of American origin, and not patented in this country, but we are not certain. At all events there are two or three makers of them in England.

HEATING GREENHOUSE FROM KITCHEN BOILER (*A. G. T.*).—There will be a difficulty in heating your greenhouse from the kitchen boiler, owing to that boiler being 3 feet above the floor of the greenhouse. The lid being moveable and open, you cannot take the pipes in the house higher than the height of the water in the boiler, and the circulation would be impeded if you had the pipes inside the house lower than the water in the boiler. If you took your pipes round the house you would need to have the pipes that height, which would spoil your doorway from the passage and the doorway into the garden. With a close lid you could take the pipes up over the doorway, but in no case must they fall more than 3 feet from the floor. If your boiler had been 3 feet below the level of the greenhouse floor you could have taken pipes round three sides of your little house on the floor level. The simplest plan for you would be to have an iron or slate tank, or a stand of water-pipes of any shape most desirable, but on the same level as the boiler, placed anywhere between the two doors, which would be quite sufficient to keep out frost—that is, presuming you must heat from the boiler. The simplest plan in the circumstances would be a small iron stove inside the house, with flat top for an evaporating-pan to be covered with a lid when much moisture was not wanted.

NOTICE TO QUIT SERVICE (*A. P.*).—Probably you would be able to compel your employer to give you a full month's notice, or an equivalent in money; but the legal expenses, loss of time, and the disinclination to engage any one who has sued his master, would more than outweigh the value of the few shillings overplus. You had better state fairly to your master your willingness to leave at the time he wishes, but that you are entitled to a week's wages in addition; and, unless he is unreasonable, or there is some fact of which we are ignorant, he will give you your full due.

DATUBA ARBOREA CUTTING-BACK (*M. F.*).—You may cut the plant back when you like; but we should prefer, if you keep the plant in a low temperature in winter, just secure from frost, to cut it back about March, and then, as the heat increased, it would break vigorously; and if the wood was well ripened every fresh shoot would produce flowers. No plant will better stand pruning or cutting-in. We prefer plants 6 feet high to those 3 feet in height, when we can give them room, as the huge flowers look best when you look up to them hanging down, or at least look to them on the level of the eye. At 3 or 4 feet high you only see the backs of the flowers.

HEATING AND GLASS FOR GREENHOUSE (*J. J.*).—We believe Mussett's apparatus answers very well. We should prefer either clear or rough glass to green, for a greenhouse, though we have little doubt but green would do. Light blue, or sky blue, does well.

PRESERVING WALNUTS.—"Can any of your correspondents inform me what will prevent Walnuts getting mouldy, when gathered and laid by?" One of your correspondents mentions they may be kept moist by being placed in jars and kept in a cellar; but this will not prevent their getting mouldy, which they do first outside the shell, then inside the shell; the skin that covers the kernel becomes mouldy, and afterwards black, and soon the nut decays.—A. G. L." [We shall be obliged by information on this point. We wash them thoroughly, and then keep them in jars in a cold cellar, without their becoming mouldy.]

PROPAGATING WINTER CHERRY (*A. Subscriber*).—The fruit is that of the Winter Cherry (*Phytalis alkekengi*), a hardy herbaceous plant, readily increased by seed sown in spring. It is best removed in March, and the roots divided, which is a ready mode of propagating it. It will grow almost anywhere, but prefers light sandy loamy soil.

BOOKS (*H. U.*).—In about a fortnight the work on Vine culture will be published. It will be advertised in our next Number. The "Cottage Gardeners' Dictionary" can be had from our office free by post for 5s. 8d.

CLIMBERS FOR HOUSE WALLS (G. C.).—We suppose you wish to cover the walls on every aspect with suitable shrubs and climbers, and other plants. North aspect : *Hedera* (*Ivy*) *algeriensis*, *Rœgneriana*, *latifolia maculata*, *palmata*, and silver-edged; *Virginia Creepers*; *Jasminum nudiflorum*, flowering in January; and *Cotoneaster microphylla*. East and west aspect : *Berberis Darwinii*; *Clematis* *azurea grandiflora*, *Sieboldi*, *lanuginosa* and its variety *palida*, *fiammula* (sweet scented), *Hendersoni*, *viticella atrocitra*; *Atragene austriaca*; *Chimonanthus fragrans*; *Craffægus pyracantha* (*Evergreen Thorn*); *Fyrus japonica*, red and white; *Jasminum revolutum*, white and sweet; *Honeysuckles*—viz., *flexuosa* (*scarlet*), *Trumpet*, *Dutch*, *early and late*; and of *Roses*—*Ayrshire*, *Splendens*, *Dundee Rambler*, *Queen of the Belgians*, *Alice Gray*, *Ruga*, and *Thoresbyana*; *Evergreen*, *Princess Marie*, *Myrianthes*, *Williams's Climbing*, *Princess Louise*, *Felicité Perpetue*, and *Adelaide d'Orléans*; *Hybrid*, *Madame d'Arblay* and *The Garland*; *Boursault*, *Inermis*, *Amadis* or *Crimson*, and *Gracilis*; *Multijora*, *Laura Davoust*, *Tricolor*, *Purpurea*, and *Russelliana*. South aspect : *Aristolochia* *siphon*; *Lonicera* *aureo-reticulata*, *fragrantissima*, and *brachypoda*; also evergreen *Honeysuckle*; *Eugenia Ugni*; *Wistaria sinensis* and its variety *alba*; *Passiflora* *cerulea* and *grandiflora*; *Periploca graeca*; *Magnolia* *grandiflora*; *Jasminum Wallichianum*; *Hypericum nepalense*; *Escallonia pteroclada* and *montevideana*; *Ligustrum japonicum*; *Ceanothus intermedius*, *azureus*, and *hybridus*; *Bignonia* *radicans major* and *grandiflora*; *Banksia* *Roses*, *Jaune vif*, *Fortuniana* (white and yellow), and *Jaune serin*; *Noisette*, *Janne Desprez*, *Cloth of Gold*, *Sofatere* or *Augusta*, *Triomphe de Bolwyller*, *Ophirie*, and *Lamarque*.

MAURANDYA BARCIAYANA WINTERING (An Amateur).—We fear this creeper would not bear the vigours of an ordinary winter in the West Riding of Yorkshire if matted up. If you mat it up, covering with a good thickness of straw, and then with Russia mats sufficient to prevent frost penetrating, there is no doubt that it might be kept over winter as you propose. We have no experience in the matter, and are content to take cuttings in autumn, keeping them over the winter in a cool greenhouse, and letting the old plants take their chance. Why not try to keep it over the winter matted up? and so settle a question in horticulture for yourself. If you do, and succeed, we shall be glad to hear of it.

HYACINTHS IN WATER (V. G. C.).—You placed the Hyacinths too early in the glasses, October being quite early enough, and the bulbs themselves might not be over sound at the base to begin with. Too much care cannot be taken in selecting bulbs that are sound, and it is a point requiring some judgment and experience. When Hyacinths are placed in water early they remain too long inactive, or are liable to rot at the base, the main point being to secure a speedy protrusion of roots after the bulbs are placed in the glasses; for if they remain any length of time over water in a dormant state the base must rot, from the moisture at that part. It is best, therefore, not to place them in water until October, when we may calculate on a speedy growth. The grubs in the water are probably the larvae of the gnat which is plentiful in most soft-water tanks. It is not likely that they would be able to leave the water and go on to the bulb unless it touched the water, when they might, and they would then do irreparable mischief. If you strain the water through a piece of muslin you may keep such insects out of the glasses. We know of nothing that will kill them and yet be harmless to vegetable life. Having changed the water, place a piece of charcoal at the bottom of the glasses, and place them in a dry cupboard.

CONSTRUCTING A PIT (F. T. C.).—You may do as you propose, but you will act wisely if you dispense with your holes in the wall (pigeon-holed wall), and build it solid. This will enable you to dispense with any very secure platform of boards, &c., and the more open the boards, &c., are, the better will the heat rise. With your holes in the wall there would be danger of steam, and moisture, and damp from the dung. In severe weather you would have to pack up to the top of the frame or pit with litter, or tie straw against it. You will find such a place answer well also for hardening off. All that is necessary, provided there should be a little heat against the walls, would merely be giving abundance of air. In most cases where there is not abundance of litter you would find a brick Arnott's stove and some mats the cheapest and best mode. However your plan, but with solid walls, will do admirably. If open-walled your platform must be secure against steam from the dung. The distance of the platform from the glass must depend on the size of the plants. For rather small plants 20 inches would be a good distance. If the pit is deep provision should be made for altering the platform, and the best mode would be to have two-inch ledges of brick formed inside in building, say at 20 and 30 inches from the glass.

FAILURE OF BLACK FRONTIGNAN GRAPE (F. F.).—Your Black Frontignan would be improved by placing glass over the border. The White Frontignan would do well grafted on it, and is not liable to shank or shrivel. The Muscat Hamburg will do well inarched on the Alicante, and Lady Downes' will do as well as the Hamburg and keep rather longer than West St. Peter's.

VINES FAILED IN POTS (J. O., Bradford).—Unless we saw and knew what the Vines had done we could not say what they would do next year. As they did little good this season they might do well next year if the wood is good and well ripened. If the wood is weak and not firm we could hold out no great prospect of success. When Vines in pots once bear heavily they do little good afterwards. If they bear only moderately, and the wood is moderately strong and firm, the same Vines will produce for years. As you have the plants they would be worth trying. In neither case will it be worth while to place them out of doors, unless in front of a south wall to harden the wood. The pots must be protected. If you want to force early, as soon as the leaves colour the pots might be placed on the north side of a fence to rest the Vines before again exciting them.

WHITE WATER LILY PLANTING (A. K. H.).—The best time is in April when growth is commencing. Take them up carefully with as much of the thick fleshy stem as possible, and if kept some time out of water, pack in damp moss and keep from the drying influences of the atmosphere. The plants cannot be too soon planted in their permanent positions after they are taken out of the water. If the pond bottom consists of mud, or the bottom is a strong loam, nothing will be required but to tie a stone to the root of the plant, and having fastened it firmly drop the whole in the place desired. The depth of water should not be less than 1 foot nor more than 3 feet. If there is no mud and the bottom is gravel, place the plant on the underside of a thick sod, tying it fast with wire, and then drop it into the place desired, taking care to place it with the crown upwards. If the above modes cannot be adopted you may pot the plants in strong loam, fastening them with stones to prevent them rising, and then place pot and all in the water.

ORNAMENTAL BORDER SHRUBS IN POTS (De Poix).—We are promised some notes on this subject, and will publish them forthwith.

BLUE WOOD ANEMONE ROOTS.—A Subscriber would be much obliged by being informed where these can be obtained.

NAMES OF FRUIT.—(J. Rust).—Your Apple is unknown to us. (Mr. Porter).

Pears.—2, *Beurré de Capiaumont*; 3, *Beurré Bois*; 4, *Easter Beurré*; 5, *Beurré d'Aremberg*. Others not recognised. (H. B.).—1, *Reinette du Canada*; 2, *Boston Russet*; 3, Not recognised; 4, *Franklin's Golden Pippin*; 5, *Herefordshire Pearmain*; 6, *English Codlin*; 7, *Lady's Finger*; 8, *Kerry Pippin*; 9, *Bedfordshire Foundling*; 10, *Early Nonpareil*; 11, *Vaughan's Pippin*; 13, This seedling is a good summer cooking Apple, but is already past. Others not recognised. (G. R. Bigge).—A, *Hollandbury*; B, *Golden Pippin*; C, *Devonshire Quarrenden*; D, *Yellow Ingeshire*; E, *Fearn's Pippin*; (Fruit-eater).—Pears.—1, *Achan*; 2, *Gansel's Bergamot*; 4, a very small *Beurré Clairagean*. Apples.—6, *Trumpington*; 4, 5, and 7, are alike and unknown; 8, *Vaughan's Pippin*. Others not recognised. (Iago).—Pears.—1, Quite decayed; 2, Quite rotten; 3, *Louise Bonne of Jersey*; 4, *Ganeel's Bergamot*; 5, *Beurré Diel*; 6, Quite decayed. Apples.—1, *Kerry Pippin*; 2, *Duch Codlin*; 6, *English Codlin*; 9, *Winter Codlin*; 12, *Brookes*; 13, *Braddick's Nonpareil*; 15, *Carrel's Seedling*; 16, *French Crab*. Others not recognised. (C. R. P.).—1, *Margil*; 2, *Keeping Redstreak*, (G. O.).—Your Apple is Pearson's Plate. (G. M.).—Emperor Alexander Apple. (B.).—1, *Glou Morceau*; 2, *Marie Louise*; 3, *Ne Plus Meuris*; 4, *Flemish Beauty*; 5, *Glou Morceau*; 6, *Napoleon*. (J. P., *Longford*).—1, *Beurré Rennes*; 3, *Napoleon*; 4, *Louise Bonne of Jersey*. (W. A.).—1, *Vicar of Winkfield*; 2, *Easter Beurré*; 3, *Autumn Pearmain*; 4, *Blenheim Pippin*; 5, *Dumelow's Seedling*; 6, *French Crab*; 7, *Hampshire Yellow*; 8, *Golden Winter Pearmain*; 9, *Russet Pearmain*; 10, *Scarlet Nonpareil*. (A Young Pomologist).—1, *Cellini*; 2, *Beauty of Kent*; 3, *Reinette du Canada*; 4, *Blenheim Pippin*; 5, *Golden Reinette*; 6, *Margil*; 8, *Franklin's Golden Pippin*; 9, *Cockle Pippin*; 10, *Golden Noble*? (R. C. H.).—Your Grape is Early Malingre (see Hogg's "Fruit Manual"), certainly not White Frontignan. It has no Muscat flavour.

NAMES OF PLANTS (A Flintshire Subscriber).—2, *Cheilanthes radiata*; 3, *Pteris longifolia*; 4, *Asplenium circinatum*; 5 and 7, *Adiantum pubescens*; 6, Some imperfect *Adiantum*; 8, *Blechnum occidentale*. Henslow's "Dictionary of Botanical Terms" is what its name indicates, but it does not translate the names of plants. The "Cottage Gardeners' Dictionary" translates the names. (W. H. M.).—We cannot detect a plant's name from such a dead mashed leaf. Good specimens should be sent.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ISLINGTON AGRICULTURAL HALL POULTRY SHOW AND THE BRAHMAS.

I AM not going to inflict on your readers another analysis of the leading shows as to relative entries, but I should like to draw the attention of the advisers of the grandmother of poultry shows to certain facts, illustrated by the Show just held at the Agricultural Hall.

Thanks to the proceedings of the Crystal Palace authorities, the Show just held has been the first opportunity that has occurred for gauging the various breeds as regards the produce of 1864, and I venture to say that not a few persons who examine the catalogue will be exceedingly surprised, not the least, I suspect, those who have cast on the Brahma the stigma of impurity. What are poultry breeders about, when so many pure breeds are to be found, that such an increasing number should pet this despised race? Could it have been supposed a year or two ago that at the first great chicken show in 1864, Brahmams would have held the position they do?

Setting aside Bantams, the prizes for which were certainly too small, Brahmams enter more largely than any other breed, in proportion to the prizes offered. The Dorking alone approaches them. True, there were ninety-three pens of Game to fifty of Brahmams, but the former had nearly three times the amount of prize money offered, setting aside the much greater facility for making up pens, now generally conceded to Game—viz., that only one lady is exhibited.

Brahma breeders owe a deep debt of gratitude to the authorities at the Agricultural Hall. Through evil report and good report they have befriended the Brahma. They have consistently dealt liberally towards them, more liberally, in fact, than any other schedule-framers, and I think the result must have proved to every one the justice of their deeds. At any rate, they must have this satisfaction, that at no previous show has there ever been an exhibition of Brahma birds equal to that just held. I am not now speaking of the quality, but from the high commendations bestowed, I imagine that was not lacking. All success then, say I, to Islington, and its promoters. Never mind, whether it is the "Poultry Club" or not, the old proverb says that "Handsome is that handsome does," and that Islington has acted handsomely to us despised Brahmams there is no doubt. I would ask those who malign us to look at the Regu-

lations of the Show. No. 1 runs thus—"The Judges, whom the Poultry Club will select, will be empowered to withhold a prize or prizes for want of merit or competition, but additional prizes will be given where the entries are numerous and meritorious." This blue ribbon of distinction was reserved for Brahma. I trust Mrs. Birmingham will make a note of it; this, too, at a show, where Dark and Light birds were divided, and a class for pullets added. Judging from the prize list, amongst all the classes for single cocks, there could not have been one with a more severe competition than the Brahma, thirteen entries, eight being named in the prize list.

Then hail to merry Islington,
And to the Poultry C—
And when they next do hold a Show,
May I be there to see.

—Y. B. A. Z.

[We hope we may meet you there, and that then the classes may be better arranged. May White and Coloured Dorkings be separated, and Polands of all sorts be unmixed.]

GAME FOWLS AT THE ISLINGTON POULTRY SHOW.

As an exhibitor of Game fowls, I attended the Poultry Show at Islington last week, and you may imagine what my surprise was, after devoting almost a year's trouble and expense, and taking great pains to breed chickens in January, to see the following words written in pencil on one of my pens. "Disqualified. Old birds."

I immediately spoke to Mr. Douglas on the subject, and he told me that he had given it as his opinion at the time they were judged, that the birds were chickens of this year, and he still entertained the same opinion about them, but that the Judge would have it to the contrary, and there was no appeal from his judgment. Now, Mr. Editor, after a man like Mr. Douglas (who, I suppose, has been the most successful exhibitor of Game in England), gives it as his unqualified opinion that my birds were bred this year, I do not think the person who judged them could have had much knowledge about a bird, or he never would have indulged in such a strange freak as he did.

My principal object in writing to you is, that you may publish this letter to clear my character from an unjust imputation which has been thrown on it by some one who ought to have known better.

In conclusion I must say, that I think the rules of the Poultry Club have been compiled by the members solely with an idea of pleasing their own fancies. If such were not the case, I do not think we should have seen prizes as thickly distributed to the members as they were.—GEORGE W. RANWELL, Kingston Crescent, Portsea, Hants.

POULTRY SHOWS NORTH AND SOUTH.

THE remark has been made that more poultry shows are held in the north of England than in the south, notwithstanding that the south is more favoured by climate.

I think I can discern the cause. In the north they keep fowls more for eggs. The Rose-combed Everyday-layers are there the favourites; Silver and Golden-pencilled, Golden and Silver Pheasant-marked, Redcaps, and Black and White Everlastings (I object to the name "Hamburgs"), are there admired and exhibited, many of the shows appropriating five or six classes to them, which are eagerly filled by the neighbouring fanciers.

In the south—that is, in Kent, Surrey, Sussex, and Hants—those Everyday-layers are scarcely known; and as the breeders here keep fowls only for rearing chickens, the coloured legs and non-sitting propensity of that sort is directly against their being kept. Yet our southern poultry committees are so blind to their own interest, or so ignorant of the poultry fancy, that they still reserve four or more classes for those north-country breeds, while all the southern varieties must compete in one class. This is, in my opinion, the cause of the failure of poultry exhibitions in this part of England. As for Shows, we have the Islington, the Tunbridge Wells, the Brighton, and the Maidstone. The

Rose-combed Everyday-layers for the north, the Spanish, Shanghais, and Brahma for such places as Birmingham and Liverpool, and Game for all England; but for the home counties the varieties of the Dorking, or Surrey and Sussex fowls, are the birds for exhibition.

I have just returned from the Agricultural Exhibition at Tunbridge Wells, where I was forcibly reminded of the above fact. There the Dorkings, though they had only one class, yet made half the exhibition; while the four classes of Rose-combed Everlastings (*alias* Hamburgs), had not many more entries than classes; Cochins and Brahma no entries.

Can anything be plainer than that if the southern committees wish their poultry shows to be a success they must, like the northern managers, patronise their local breeds? Let them give the Dorkings five or six classes—namely, White Dorkings, Cuckoo, Grey, Speckled, and any other coloured; then, as the neighbouring breeders find these varieties patronised, they will join in the exhibition, and instead of regarding it (as the many now do), as a sort of rare show, they will in a year or two become interested supporters. I beg to request the committees of our southern shows to consider this question for another year; for I am sorry to say that even the London Show does not give the Dorkings a fair chance, for there only two classes are offered for all varieties, the White and Silver-Greys being mixed in one. Is this fair? I repeat the Dorkings should have five classes—1, White; 2, Silver-Grey; 3, Cuckoo; 4, Speckled; and 5, Other colours; then, and not till then, will they have justice done them.

I have been referring more particularly to the southern shows. I do not wish it to be supposed that I desire the Rose-comb Everlasting layers to have less respect shown them; but I contend that in this part of England Dorkings are entitled to an equal if not a larger amount of encouragement.

It is all very well to divide the Brahma into Dark and Light (though they are only varieties of Shanghais), yet would it not be better to separate the Spanish into Black, White, and Blue?—B. P. BRENT, Dallington, Sussex.

ERRORS IN THE ISLINGTON PRIZE LIST.

I SEE you have an error in the prize list of the Islington Show. You have it the same as it is in the official prize list, which is incorrect I should fancy—viz., Class 14, Brown Reds, Mr. Fletcher first, second, and third, whereas he only showed two pens, numbered 201 first prize, 202 third prize. Mr. Dyas showed pen 195, to which is awarded second prize. Also in Class 15, Duckwing Greys and Blues, you have it Mr. Aykroyd first, which is right, and Mr. Mathews second and commended, whereas he only showed one pen in that class; the second prize was numbered 208, which belonged to Mr. Everard; third, Mr. Fletcher, which is right. Now you will stop a good deal of dubious feeling if you will inquire into the matter, and put it right in your next Number.—THOMAS J. SMITH.

P.S.—You do not give the names of the Judges.

[We corrected one error, the name in the prize list being "Rose" instead of "Pease;" and we are requested to correct another—viz., the second-prize single Spanish cock belonged to Mr. W. R. Bull, not Bell. We have no means of ascertaining now whether our correspondent is correct in what he concludes. We did not publish the names of the Judges because they were not officially announced, but we heard that Mr. Teebay judged the Spanish, Brahma, and Cochin-Chinas; Mr. Dixon, Polands and Hamburgs; Mr. Challoner, Game and Game Bantams. Who the other classes were judged by we did not hear.]

BRAHMA POOTRAS AT THE ISLINGTON SHOW.

THE wise policy of the Islington authorities in dividing the Brahma class has been signally justified by the result. The Brahma ranked among the five most numerous breeds at the late Show; they equalled the combined muster of the four varieties of Hamburg fowls, more than doubled the Spanish, and were just six times as numerous as the Poles. The new class of Light Brahma exceeded in its numbers

thirty-two out of the fifty classes of poultry, &c., which formed the Show; and among the classes numerically inferior to the Light Brahmans were the four Hamburg varieties, and all the Game classes except the Reds. In single cocks the Brahmans stood second in number, being surpassed only by the Game Bantams. These figures are encouraging as to the future of the Brahmans; for if, at the first Show which recognises their right to division, they make so creditable a muster, we may fairly count upon increased numbers at future shows, when the ranks of the Light variety will be swelled by the birds of those breeders who, discontinuing to keep a breed so strangely ignored, will gladly return to their old favourites, now that justice is done to them.—BRAHMA POOTRA.

SILVER-BUFF COCHIN-CHINA FOWLS.

In your report of the Uttoxeter Show you say in your remarks about Cochins, "Mr. Stretch here exhibited a most excellent pen for size and general characteristics, but of feather most difficult to describe." The description of birds alluded to I have occasionally exhibited for several years, and although I have seen them frequently described in your columns as "Silver-Cinnamon," I have always considered it a wrong designation; for, according to written authorities, a cinnamon in Cochins is a reddish brown, or the colour of wetted cinnamon, and the Silver variety has a cinnamon hackle, and the body colour a sort of French white, or the same mottled with cinnamon. Now, the birds in question differ from the above, having a golden-coloured hackle, both cocks and hens. The former have a buff ground colour, most of the feathers edged with a silvery colour on the side of the wings and backs; and the latter, the body colour more or less of a neutral buff. I have usually called them "Silver-Buffs," and I think that is the correct designation; for as there are Cinnamons and Silver-Cinnamon varieties so called, why not one of Buffs and another of Silver-Buffs?—THOMAS STRETCH, Ormskirk.

[“Silver-Buffs” we think is a good distinctive name for these birds.]

HEDGEHOGS.

THE man who has the care of my cows informed me, to-day, that some milk had been taken from one of them at night. From the moist state of the teat sucked he attributed the loss to a hedgehog. Is it a fact that hedgehogs have milked cows at pasture, or is it merely a vulgar error?

—J. J. T.

[All good authorities decide that it is an error to suppose that the hedgehog sucks the cow when she is lying down at pasture. If your cow had any milk taken from her, we should conclude, without any hesitation, that it was by a hand.]

BEEES AND THEIR MANAGEMENT.

An increased interest has recently been excited, which is not likely to abate, in the propagation and preservation of an insect whose instincts and labours clearly indicate that it was intended for human appropriation and benefit; and, although a new branch of commerce has not been opened, an impulse has been given to an old and neglected one, which, in its aggregate results, may assume the character of a tributary stream to the wide current of our national prosperity. Let a comparison be instituted, first, between the quantity of honey of foreign import and of home production; and, secondly, between that which is and that which might be obtained from ample resources within our reach, and the result will show that we are sending abroad for the very article which abounds in our own rural districts, and lies at our very doors ungathered. The extent of bee farms,—of floral acreage, still unstocked, vastly exceeds that which is turned to any profitable account.

These considerations have an important financial bearing, and point to a source of income which has not yet found its way into the tax-gatherer's schedules, and can be assessed only at the rate of ordinary skill and patient perseverance. Let those who can, keep bees. Of course a given extent of

country can only maintain a certain number of hives. If I may hazard a conjecture, I should say that for every 100 acres throughout our midland district we might apportion two hives. This is merely a rough guess, and probably below the mark. This estimate, I am convinced, is on the safe side. If I were asked for absolute data on which to base an opinion, my estimate would assume this shape:—For capital invested take each stock-hive at £1 value, then £20 would be the amount of capital required for a bee-farm of 1000 acres. Taking the average of good and bad honey seasons, we may assume, and that quite within the mark, that each hive will yield, one year with another, 10 lbs. of honey. Reckoning the value of this at 1s. a-pound, we have £10 sterling as the interest of a capital of £20, a return of exactly 50 per cent.

If I am, as I believe to be the case, within the mark, what can be a better or safer investment than a few full bee-hives? Our cousins across the Atlantic—Heaven help them to their senses and the pursuits of peace!—keenly appreciate the value of an apiary, and know how to manage it. We are indebted to them for some new forms of hive-construction, which promise to be of great utility, and in the science, no less than the practice of bee-farming, they are, I suspect, in advance of ourselves.

Let me now proceed to the discussion of a few facts and suggestions culled from the mass of correspondence with which I have been almost overwhelmed:—First, as to the best aspect for an apiary. Get as much unobstructed sunshine as possible from the S.E. to W., and as much shelter as you can obtain from every other point. The intervention of a low wall or fence as a screen from the S.W. prevalent wind will be an advantage, provided it does not interfere with sunshine from that quarter.

I have a range of open hives with a S.E. aspect, sheltered and shaded from every other point but that included between S.E. and S.W., while my apiary has an aspect which embraces the points from S.S.E. to W.

The open hives receive the sunshine first, and part with it soonest. The effect is curious and instructive. The bees in the open hives are the soonest on the alert; those in the apiary continue their work the longest. With respect to the quantity of honey collected in a given time, I cannot note any difference. In Holland it is said that bee-hives are generally placed with a north aspect, in which they thrive remarkably well (*Vide COTTAGE GARDENER*, vol. v., p. 76).

I have not sufficient confidence in the result to try the experiment myself, nor do I know of any one who has. I do not like hives to be enclosed in bee-houses; they are better, in my opinion, exposed to the free currents of the external atmosphere. A warm blanket of stagnant air often proves a wet one. Bees will bear the lowest winter temperature unhurt, but a moist hygrometric condition is fatal. A sudden increase of atmospheric temperature causes a deposition of moisture within a bee-house, which affects the health of these insects more than anything else. Place the hives in an open shed, the darker the better in winter, and let the wind blow around them.

Secondly, as to swarming, my advice is to learn its indications, which have been described in the *Times*, and may be read in any manual of bee-keeping. See, if possible, a swarm hived, and remember that the object is to secure the queen. I have found that, as a rule, it is only in very warm weather that bees invariably hang out. I have mostly (this May was a partial exception) no other warning than a sudden cessation from their work, the bees spreading themselves in numbers of forty or fifty on the alighting-board an hour or two before the queen comes out. When the nights are cold, and the hives are full, the great increase of temperature in the interior shows itself in a long broad streak of deposited moisture at the opening of the hive, commonly called sweating. When this is seen keep a sharp look-out on the morrow, if fine, from 10 A.M. to 2 P.M. If the bees be perceived holding intercourse with their “antennæ,” in groups of ten or twelve on the front board, and labour slackens, you may expect a swarm.

I have frequently seen a swarm on the point of taking a flight kept back by the passage of a cloud across the sun. When the anxious moment comes, and the melodious and unmistakeable hum of 15,000 or 20,000 bees proclaims them on the wing, let the watcher retire to a respectful distance,

especially keep children, in fact all but experts, out of harm's way, for if the queen, in a fit of perversity or weakness, were to alight on the head of even an experienced bee-keeper the swarm might be hived, but it would be at the very imminent peril of human life. When they have all settled, and are quiet, hive them according to the best experience or directions obtainable.

But thirdly, hiving is not always an easy matter. Bees will not always go where you wish them, frequently where you least expect them. This is a point to be considered in the establishment of an apiary. The first step in this, as in other things, is the most important. The best locality, at least one which in my case has proved most satisfactory, is the sheltered corner of a kitchen garden, with rows of currant trees in front. The majority, by far, of my swarms have alighted on currant trees, although some have selected raspberry trees in preference, and they have not unfrequently settled on the part where the canes are secured to the stakes. In this case the greatest care is required in handling the swarm, lest the queen should be crushed. The only thing to be done is either to cut through the canes below the bees, and bending the stake over the hive, to give it a sharp rap, and thus house the swarm; or, as I have mostly done, to cut out only a few of the canes, so as to make an opening through which the bees are precipitated when dislodged. A knowing hand will always mark where the bees first begin to cluster, and will take especial care to get that part of the swarm hived first, well aware that the queen is there, and that, if secured, the rest of the bees will be sure to follow. It is a great point with me to ascertain this, if possible, and I have on two or three occasions found it of immense advantage to do so. Two years ago I had a large swarm alight on the thick stem of a large plum tree, where the shaking principle could not be brought to bear. There was, of course, no grape-like pendant clustering. The stem was bandaged with a large thick poultice of winged life. I knew whereabouts in the mass her apian majesty was located, and, with a housemaid's dusting brush, I had little difficulty in getting her into my power, and then at my leisure swept the remaining bees from the stem to the sheet, on which the hive was placed beneath the tree. I once had a swarm drop in the centre of a thick and tangled row of peas, and, instead of clustering into a compact mass, the bees spread themselves over a space bordering upon 15 or 16 inches square. I did not see where the queen alighted, and failed in my first attempt to hive her. Fortunately, however, I noticed a small cluster of bees on the ground, and on separating them found the queen. Taking her gently up between my finger and thumb, I placed her under the hive, and the swarm was secured.—WILLIAM LAW, Marston Trussell Rectory, Theddington, Rugby.

(To be continued.)

DARK-COLOURED HONEY—BEE FOOD— WOODBURY FRAME-HIVES.

I SEE in THE JOURNAL OF HORTICULTURE for last week, this answer to a correspondent. "The dark colour of your honey this year is owing to some peculiarity of the season and its effects upon the pasturage." Now, I dare hardly venture to have an opinion contrary to that of the Editors of the Journal, but I had made up my mind that the dark colour was owing to the honeydew. I never remember so much as there has been during the latter part of this summer—viz., the last week or so of July and the whole of August. Now, I found that the storing of dark honey was coincident with these honeydews, and this autumn, when removing supers, it was quite curious to observe how plainly and distinctly you could mark the change from the purest white to this dark honey. All that I have taken since August has not only the colour, but also the flavour, of coarse brown sugar syrup, and I have handed over some 15 lbs. or so to the nursery and kitchen, where it is appreciated.

Secondly. I see a letter in the same Number headed, "Are Bees Omnivorous?" I know nothing on this point of my own knowledge, but I feel sure that I remember hearing my brother-in-law say some years ago, before I kept bees, or took any interest in them, that he often fed his on chicken bones from the table, and occasionally gave them a blackbird, but lest I should have dreamt it, I have written to him

to ask particulars, and as he is very accurate and a good observer, I shall be fully satisfied with his reply, which I will forward to you if you desire it. And now I would ask a question. Three years ago I procured a Woodbury bar-hive, which has been most satisfactory in all respects. Two years ago I obtained a Woodbury bar-frame hive, and each year the frames have got a little out of the perpendicular as soon as the bees began to work, and thus scarcely any of the combs are true, and many are joined together so that the frames are useless. I do not wish to break up this stock this autumn. Can I, now or next spring, take out each bar and prune and straighten the combs, and then how can I keep them straight?

Query 2. Is the borage, so much recommended as bee food, the common rough-leaved blue borage? If so, where can the seed be obtained, and would it answer to sow some quarter of an acre of poor land with it?—A. W. B.

[You may very probably be right in connecting the collection of dark-coloured honey with the existence of honeydew, but we do not deem this opinion contrary to our own. Honeydews do not always produce thick dark-coloured honey, and its very general appearance this summer we still believe to be owing to some peculiarity in the season and its effects upon the pasturage.

We shall be glad of any evidence with regard to the carnivorous propensities attributed to bees.

Every Woodbury frame-hive either is, or should be, furnished with a notched bar fitted transversely at the bottom of the hive. Each frame drops into its appropriate notch, and is in this way kept perfectly steady and perpendicular until filled with comb. When this has been accomplished the notched bar had better be removed as the weight of the combs renders its presence unnecessary, and it would be a hindrance to their free manipulation. During any warm day in either April or May the combs may readily be set straight; and if kept in their proper position by clips formed of tin or sheet zinc, strips of wood, wire, or other temporary supports, they will in twenty-four hours be so firmly fixed by the bees that all extraneous appliances may be safely removed.

The plant referred to is the common blue borage. The seed may be procured of any seedsman, and, once sown, it will probably increase and multiply fast enough.]

JOINING LIGURIAN QUEENS AND BEES TO BLACK BEES.

I OBSERVE in some of your last Numbers that you seem to doubt the joining of Ligurian and black bees together. I have lately joined four hives, first taking the black queen away, and without the least fighting. This I have done by fumigation, joining during the time they are fumigated. I do not observe any of your apiarians have hit upon a sure plan of joining Ligurian queens to black bees; but I have joined several by fumigation, taking the black queens away first; or, if they are in frame-hives, it saves a great deal of trouble to first take away the black queen, and when the bees have settled in the evening, to fumigate them, and then join the queen, which need not be fumigated. Care is required after fumigation that they be shut in until they recover, and plenty of air (warm, not cold) given, and that they be let out next morning. By this plan you may join three or four hives together.—A. W.

FOUL BROOD IN YORKSHIRE.

ON perusing Mr. Woodbury's reply, that the sample of comb sent from my hive "was unquestionably foul brood," and that he "never saw any presenting a worse appearance," I felt that, at this late season of the year, it would be the wisest course to take his advice, and destroy both my infected colonies.

I did not, however, like the opportunity of trying the cure of this fell disease to pass away, and, therefore, determined on making the attempt. I should say that both the diseased stocks are Ligurians (though in the older one the breed is not so pure), and that they were both in Woodbury frame-hives.

I first removed the queen from each hive, and then pro-

ceeded to drive the bees out. I do not know whether it is the experience of others, but I found, as I have before done, that "driving" bees from boxes is very "slow," and after drumming for about ten minutes with very small results, proceeded to brush the bees from the combs with a feather into an empty hive, and, putting them on their stand, they all went in at night, when I fastened them up.

I found eggs and brood in all stages in both the stocks. The next day I united the bees, making use of syrup flavoured with peppermint, and put them into a probationary box having two sides of glass, sufficient ventilation being secured by the bottom being made of one piece of perforated zinc, and by large openings in the top board covered with slides of the same material.

The total nett weight of bees was a little more than 2½ lbs. I should be glad if you or any of your correspondents would say what is about the weight of bees in a strong stock at this season. My own idea is, that with the killing of the drones, and the great numbers that die and are destroyed in various ways without being to any great extent replaced by brood, that few stocks would have more than half the weight of bees that they had three months ago.

Placing the best queen with about fifty workers under a bell-glass at the top, I kept the bees confined for six days, giving them the queen on the fifth day without much difficulty. During the whole time the bulk of the bees hung in a cluster beneath the queen, lengthening to the bottom in the daytime and contracting into a small space at night. On once changing the position of the queen at the top, the cluster below very shortly followed. Although I could not well have given more ventilation, the excitement in the daytime once or twice sent the thermometer up to 90°. I fed them with a little syrup each day, and they made one small comb, about 12 square inches. Nearly a hundred bees died each day: in all I counted rather more than five hundred dead ones.

Thinking that there would be less danger of failure if I gave them a winter's stock of sealed honey, and a friend having proposed to drive the bees from one of his straw hives, I was glad to avail myself of this for the purpose.

On driving the bees from this stock we were surprised to find not more than $\frac{1}{4}$ lb. of them, no queen, and several drones; the hive contained 16 or 17 lbs. of honey. It is rather remarkable that this handful of queenless bees should have managed to guard their stores, being close to several strong stocks which have proved themselves adepts at robbing. There was no brood, and the combs appeared perfectly healthy. Into this hive I drove my poor imprisoned bees, and took them to a friend's garden two miles off, and where no bees are kept. Here they will remain till spring, when I propose to cut out the combs, and if I find them free from disease to transfer them to a frame-hive. If, unhappily, otherwise, they will, I think, be consigned to destruction. In this case I shall feel at least somewhat repaid by having proved to my own satisfaction that it is well nigh useless to attempt the cure of foul brood at this season of the year. In either case I intend to inform you of the result.—C. D., Sheffield.

FOUL BROOD, AND WHAT HAS BEEN WRITTEN ABOUT IT.

We are all exceedingly obliged to "R. S." for experimenting on foul brood, as well as for his kindness in making public the result of his experiments. It is, of course, pleasing to me to find those statements confirmed, which it is now needless to say were not only free from exaggeration, but were penned in sad and sober earnest, and without even the slightest intention of astonishing apiarians generally.

I may remark that "R. S." is the "valued correspondent in the north," to whom I alluded in page 408 of the fifth volume of THE JOURNAL OF HORTICULTURE, and that I am informed by him that all his observations and experiments have gone to establish ALL that I have stated regarding the infectious character of the disease.

Since concluding in page 446 of the last volume of THE JOURNAL OF HORTICULTURE the series of papers under the title which heads this article, my attention has been drawn to the fact that in Bonner's "Bee-Master's Companion,"

published at Berwick in 1789, foul brood is accurately described, a whole chapter being devoted to it under the title of "An uncommon disaster, which sometimes, though rarely, happens bees," and in which he says—"I shall here narrate a very strange disaster which happened to four of my hives last spring; which, for the singularity of it, I hope the reader will excuse me for relating here. In the latter end of March I had four hives that had but few bees in them, and also but very little honey, and consequently, could neither have defended themselves from robbers nor famine. To put them in a way of defence from both, I supplied every hive with a sufficiency of honey to bring her to June, and also after two days reinforced her with bees to defend her from robbers; after, in the first week of April, I took the four hives a mile from my own apiary, and placed them in a sunny, quiet place among whins which were beginning to bloom, and near some sallow trees, whose palms were out, so that when the weather was fine they had food at their door without the trouble of much travel. . . . As soon as they were well set down among the whins the weather turned very good, and my four mended hives fell briskly to work and wrought throng for twelve days of fine weather." Bad and cold weather then set in, but in due time "good and pleasant weather comes round again, and my strong hives fell briskly to work; whilst scarcely a bee was to be seen at the entry of any of my mended hives. I was surprised at it, as knowing it was neither for want of bees nor honey. I then turned them up, and by looking down between the combs, I saw plainly that the young were all going backward in the cells. I waited other eight days, and none of the bees ever carried any at all, while my strong ones carried throng. I then turned them up again, and cut out a large piece of comb with maggots in it, and found every one of them dead, and going backward in the cells; as it was such a case as I was perfectly a stranger to, I could not know the cause how it happened, neither did I presently know what method to take with them next. I conjectured that every hive having got so many bees, and so much honey added to them; at the same time placed in the midst of good pasture, to which the sun added his comfortable presence, all which completed their happiness, and set them a-thinking summer was at hand, and now they should set to prepare for it, by hatching forward a numerous brood, which they accordingly had done, and had a vast number in their cells, considering the season of the year, and the short time they had; and also their number was not very great, although they had a moderate quantity. I also conjectured that as the queen had been made prolific by the heat in the hive, to lay great quantities of eggs, the bees had also to go off in large quantities a-foraging among the flowers for fresh farina to seal the maggots up in their cells with, and when so many were abroad, the few that remained at home could not keep a sufficient heat in the hive to nourish up so large a brood." Blaming "excessive cold" as the cause of his disaster, Bonner "waited till the beginning of June, and the bees turned very few, the old ones dying of age, and few or none to supply them; they decreased very fast from the time of the disaster to the beginning of June, they carried loads, and bred some, but very little. When I turned them up in May and June, and looked down between the combs, I was unable to do it for the stench that the rotten maggots produced. I then saw plainly that they never were to turn to any account the way they were presently in; for though they were beginning to tear out some of the consumed maggots, and lay eggs in their place, and increase a little, the season was going away fast, and, consequently, they would be of little value at the end of summer. . . . I then immediately proceeded and took all the bees out of one of the hives, and put in an empty one. I next took all the bees (which were very numerous) out of one of the strong hives which . . . was standing beside the mended ones, and put in another empty hive also. I then set down both the hives containing the bees in the very spot where they stood when in possession of their own hives, in order that they might keep their old stance, and then I took the hive containing the stinking maggots, and with an instrument made on purpose, cut out all the pieces of combs containing the stinking maggots, among which were two hundred young bees coming forward in some of the cells which the bees had cleaned out; but I

paid no regard to them, but cast them into my empty comb-barrel, that the cells might be made into wax the next time I made that commodity. After that I took the numerous bees which I had taken out of the strong hive, and put in the hive which I cut the combs out of, and set the bees exactly where they stood when in possession of their own hive, and they being numerous, soon filled her full of combs again. I then took the heavy hive which was almost full of maggots in the cells, and had also, I judged, 10 lbs. of honey in her. I then took the few bees which came out of the stinking hive and put in her, and set her down in the place where the few bees stood before, and covered her well, and gave her a very little entry, in order to keep her warm to hatch out the young, and in ten days time she hatched out a most numerous brood, and they were both thriving hives. I did exactly the same with the other three stinking hives, and changed their bees with three of their strong neighbouring hives, and they all did well, and gave me satisfaction, which I esteemed an excellent cure for so desperate a case."

An excellent cure, indeed, provided it were permanent, which my experience of foul brood leads me very much to doubt, especially as in a subsequent work published in 1795, our author again refers to the disease, but this time in a manner which appears to indicate that he had found it by no means so "rare" as he had previously imagined. Whatever may be thought of the means by which he attempts its cure, and the reason he assigns for its outbreak, there can be no doubt of its identity with foul brood; and as this is the earliest and best description of that disease which I have met with in any British author, I have been tempted to quote at some length from what is now a rather scarce book.—A DEVONSHIRE BEE-KEEPER.

BEES' WORKING HOURS.

WOULD some of your correspondents state the hour that bees go out foraging in the morning? as I observe in your Journal it is stated that they do not go out before 8 A.M., whereas I saw some of mine out at seven this morning, September 29th, and it was cold too. They were on the borage. I have seen bees out at half-past 6 A.M. frequently, and this last season had swarms at 8.30 A.M.—J. ELMO.

[Bees commence work early or late according to the season, and the prevailing temperature; but the strength of the colony has great influence, as it is by no means unusual to find the bees of a strong and flourishing stock on the wing long before the inhabitants of a neighbouring but less prosperous hive. We have, however, frequently seen wasps invading even strong colonies at so early an hour that no sentinels were on duty to repel them.]

THE SPIDER AND THE WAX-MOTH.

FROM the days when Virgil sang of bees the spider has been numbered among the enemies of the honey bee. In common with most bee-keepers, I waged relentless warfare against it, until my attention was called to the large numbers of bee moths often found suspended in its webs. From that time I looked upon it with a friendly eye, satisfied that while it feasted upon many an unfortunate bee, it was entitled to the same favourable regard with the insectivorous birds, which claim a share of the fruits their industry has helped to protect. Within the last two years, however, I have found it to my interest to cultivate a still more friendly acquaintance with this detested insect, as I am now able by its help to preserve all my empty combs from the ravages of the bee moth. Let me tell your readers how I came to make so useful a discovery.

Two years ago I placed a small hive, containing an Italian queen, from which I was raising other queens, upon an empty old box-hive, which, being laid on its side, furnished a convenient stand for my nucleus. Putting some frames with the empty combs for a few days in the box-hive, where they were protected from the sun and weather, and were convenient for replacing frames of brood removed from the nucleus, I noticed that a spider soon spun her web among them, and that in a few days she had caught several bee

moths. During the season I used this place as a receptacle for empty combs, and never saw any indication that the bee moths had deposited any eggs amongst them. Last year I used the box in the same way, with similar results. Encouraged by this success, I left early last spring a number of empty combs in hives untenanted by bees, and find them, after repeated examinations, protected by spiders, and as free from the depredations of the larvæ of the bee moth as though they had never been without the protection of the strongest colonies of bees.

Those who have kept pace with the progress of improved bee culture, have long ceased to regard the bee moth as a very formidable enemy to the successful rearing of bees. Populous and well-provisioned stocks suffer only trifling injuries from it, while those that fall a prey to it are usually queenless, or in such a condition as to be worthless without the aid of an experienced bee-keeper. The presence of the bee moth is most to be deplored in the apiaries of the skilful, because of the great difficulty of protecting empty combs from the ravages of its offspring. The use of moveable comb-hives enables the bee-keeper to turn to advantage every piece of good comb taken from colonies which are broken up, or to which any accident has happened, if such combs can be preserved from the only insect known to live upon wax. But if a single female moth gain access to these combs after they are removed from the bees, or if only a few eggs are deposited in them before their removal, the worms, as soon as they hatch, begin to eat the combs, and so rapid is their increase in hot weather, that in a short time such combs are rendered entirely worthless.

Both in Europe and this country many plans have been devised for the safe-keeping of empty combs, but all of them require more time and skill than bee-keepers usually have at their disposal. Once committed, however, to the faithful guardianship of the spider, they may be considered secure, whether placed in empty hives, or in any special depository made easily accessible to these watchful insects. If I found the spiders at all dilatory in taking possession I should put their egg-bags early in the season into the receptacles where I keep my empty combs, or I should capture and introduce some full-grown specimens; but thus far any hive or box placed on the ground, and having sufficient opening, has been tenanted as early in the season as I could wish.—L. L. LANGSTROTH, in *American Country Gentleman*.

OUR LETTER BOX.

PLUMAGE OF BLACK DUCKS (*Buff Cochin*).—Black Ducks should have no white feathers, but few are without some, and they are more common round the eye than on any other part of the plumage. If they were shown against birds as good in other points, and lacking these defects, they would be beaten. Old birds are far more subject to them than young ones. One or two white feathers may be found in almost every bird of the breed, unless they have been pulled out. If they are in all other respects prize birds, we do not think you would be justified in returning them.

FOWLS WITH SHOT IN THEIR CROPS (*Cecil*).—There is no cure for the case you mention—that is, there is no way of getting rid of the shots immediately; but unless they are swallowed in large numbers we do not see why they should be fatal. Fowls are tenacious of life. They live with pins in their gizzards. We have taken tin tacks out of them, and we should think that if barley meal were mixed stiff, and they were fed on it, the shots would pass away with it. Fowls will not pick up shots, and such numbers as you mention must have been poured down the throat. They will swallow anything that is put in their mouth if the beak be held closed.

DORKING COCK WITH SWOLLEN FEET (*W. B. D. A.*).—Your Dorking cock injured his feet in the fight so much, that they are too tender to carry his heavy body. All you can do for him is to put him in some place with one hen where it is very soft grass. Failing that, let him have a small run covered with hay. This is the only chance, as his weight is against him. Feed him literally—bread and milk, bread and beer, and ground oats.

BLACK BEETLES (*Annie*).—Have you tried Chase's Beetle Poison? It is said to be very effectual.

LONDON MARKETS.—OCTOBER 10.

POULTRY.

The supply of poultry does not increase, as it mostly does at this season of the year. There is, however, but a small demand, and little consequent variation in price.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 58.2°, and its night temperature 40.5°. The greatest heat was 73° on the 21st, 1831; and the lowest cold, 17°, on the 23rd, 1859. The greatest fall of rain was 0.96 inch.

ZONALE GERANIUMS AT LINTON PARK.

OME little time ago I pointed out many of the qualifications which I thought most desirable in the Zonale Geranium for bedding purposes, one being that the foliage ought to be plain and bright green rather than marked with the horseshoe, as a great many really good varieties are. In a subsequent paper Mr. Abbe very properly differs with me on this point, remarking on the many really good varieties that possess the leaf-marking, and the comparatively few kinds without it. This I by no means deny, but, on the contrary, agree in; and the list which I give of the kinds grown and flowered at Linton Park during the past summer proves that the greater number of them exhibit the horseshoe marking. But if we examine every object by the standard of excellence laid down as generally approved of by the most able censors, it will be found that comparatively few things approach that standard, and Geraniums are no exception. Although some of the sections into which I have divided the class of Geraniums here described scarcely offer an example of an entire plain leaf, I am nevertheless in hopes of seeing some of the family assume that more simple garb, and still possess all the attractive features of the best of their section. Once direct the public in the right way, and the caterers for them will on their part furnish what is wanted. The fact of some of the very best bedding Geraniums of the day lacking the black marking of the foliage is a proof that a good flower may be produced as well by a plain-leaved plant as by a zoned one. For instance: Tom Thumb and Crystal Palace Scarlet have both plain leaves, to which may be added Punch, Christine, Trentham Rose, and some others; and the markings of Stella and Magenta are faint, and might disappear entirely in another generation, and no one would wish to see these varieties changed for horseshoe-leaved ones. I am far from denying all merit in the latter class; on the contrary, in plants for a greenhouse, or where immediately under the eye of the spectator, a well-defined zone of one or more colours on the leaf, clearly and distinctly-formed, is an additional attraction to some kinds; but in the flower-bed that is to be admired at the distance of, perhaps, 50 yards or more, the less of the marking the better. Fancy Geranium Christine with a deep band of black on the foliage, and see how it would damage the rich tint of the flower! Why, it is as much the foliage as the flower that gives Christine pre-eminence over Kingsbury Pet as an old variety and Eve as a new one, both being marked in the foliage; while the white and flesh-coloured ones seem to suffer more from the confu-

sion that the two colours on the foliage create than the other sections do. I may also mention that I dislike a white eye in a scarlet Geranium as it weakens the colour; the other qualifications are so well known as to require no further comment here.

The past season has in some respects differed from former years in the well or ill doing of certain kinds of Geraniums. In the garden here the dry weather had the effect of dwarfing many of the rank growers, and inducing a profusion of bloom such as they never before exhibited, while the dwarf sorts were dwarfed still more, the individual blooms—for instance, those of Little David and Brilliant—being very small. The season throughout must, however, be regarded as having been favourable to the Geranium, and with the exception of Cloth of Gold and one or two others all have done well. I would suggest to those who make it their duty to furnish new kinds to try the yet unexplored tract, leading from the deepest crimson or purple we now possess to a still higher or deeper tint of the same colour; scarlets, rubies, pinks, flesh colour, and whites are plentiful enough and to spare, but little has yet been done in the direction I point out. The Nosegay class seems to offer the best medium for producing what is wanted in that way; but along with it must march a section of the more compact form of the most approved of the Zonale-leaved kinds. The Silver-edged varieties require but little amendment, but the Golden ones much. To these, however, I will advert on another occasion.

In dividing the list into the following sections I by no means aver that the lines of distinction between each are clearly defined; on the contrary, they blend into each other; but as near an approach to accuracy as possible has been aimed at. The varieties named are both old and new, and though not numerous, I prefer giving only those grown here; but I should like other growers to furnish a list likewise, so that we might compare notes. Many really good kinds have only a local reputation, but with the advantages of a publication like THE JOURNAL OF HORTICULTURE there is no reason why they should not be better known; and I shall be glad to hear further remarks or criticisms on this interesting subject.

CLASS 1.—*Zonale Geraniums with white flowers; foliage plain or horseshoe-marked.*

Ethel.—Upright grower, vigorous; horseshoe marking medium; flowering trusses good and tolerably abundant. It flowers also very well as a potted plant.

Snowflake.—Dwarfer in habit than the last named, which, however, it much resembles in other respects; its flowers may possibly be a shade whiter, but it falls short of the qualities its name implies.

White Tom Thumb.—I fear that this may not be correct, as the foliage has a clear and rather dark marking, which its namesake has not. It is, however, a good variety in its class, flowering more freely than some others.

Madame Vaucher.—Strong grower, having the foliage distinctly marked; flower-truss good when the blooms are all expanded at once, which, however, is not so often the case in this class as in those of darker colours. I believe this is the best known of all the Whites, and it has many admirers.

Purity.—Foliage slightly horseshoe-marked; habit good; but flowers no improvement on Ethel.

Miriam.—Foliage slightly marked with horseshoe; habit upright and rather loose; flowers no improvement on older kinds. It may possibly be better as a pot plant.

Virgo Marie.—Foliage darker marked than the last, which it excels in most respects. Possibly it may become one of the most popular of its class, but I believe it is not very plentiful yet.

White Nosegay.—I received this under the name of *Minimun Nosegay*, but find the latter name is applied to a crimson one of the same habit. *White Nosegay*, however, has little to recommend it beyond being very dwarf; the flowers are a dull pale flesh colour rather than a clear white; it blooms abundantly, however, and may be useful as an edging.

White Ivy-leaf.—This, like the last, is far from a clear white, but, taking all its qualities into consideration, it deserves a place in every collection; even those who discard the ordinary White-flowered class admire this kind. It is liable to run into a pale pink or flesh colour.

CLASS 2.—*Flowers flesh-coloured or pale pink; foliage either plain or horseshoe-marked.*

Maiden's Blush.—Foliage slightly horseshoe-marked; habit strong, rather upright; trusses good and pretty abundant. It is one of the best of its class for beds, the uniform colouring of its petals appearing better in mass than the two-coloured kinds mentioned beneath, which, however, have their merits as pot plants.

François Desbois.—Much like the last, only the horseshoe marking is darker, and the habit a trifle more spreading; the colour of the bloom is alike in both.

Diadem.—Foliage with a rather dark horseshoe marking; habit good; flower with a pink centre, and outer limb of petal white or nearly so, giving the combination of the two colours a fleshly tint. As an ornament for the plant-house I expect this and the following will be favourites; but for bedding purposes, as stated above, I prefer the single to the two-coloured varieties.

Eugénie Mézard.—Dark horseshoe marking; habit more dwarf than the last; flowers much the same, the outer edge of the petal being paler than the centre, and on that account looking as if it were bleached with the sun. As an in-door plant it may, however, be useful.

Eve.—Strong upright grower; horseshoe marking; flower a little more pink than the above. I have not sufficiently tried this to be able to state with certainty how it will turn out.

Madame Rudersdorf.—Somewhat like *Diadem*, with, perhaps, a shade more colour, and foliage somewhat less deeply marked with the horseshoe. Like the last, I have not tried it in sufficient quantity to be able to say with certainty how it will turn out.

Lizzie.—Foliage somewhat downy, scarcely any marking; habit compact and good; flowers produced freely, but, like those of most of its class, liable to be damaged with the rain or sun.

CLASS 3.—*Flowers pink.*

Christine.—This well-known favourite is, perhaps, still the best of its class, its only fault being its tendency to produce seed-pods or spikes in greater abundance than is agreeable; in all other respects there is little to wish for.

Helen Lindsay.—This variety much resembles the last; the flowers may, perhaps, be a shade darker. Not having grown it much I am unable to say more of its merits than that it promises well.

Striking.—This, like some of those in Class 2, is a two-coloured flower, which when seen at a distance looks like a pink. The central part of the flower being darker than the outside, a mixture is produced. By no means unpleasing as a bedder, but still more to be admired as a potted plant. Foliage horseshoe-marked, and habit more robust than that of *Christine*, from which it also differs materially in colour.

Hendersoni.—For some years I had under this name a dwarf variety of the *Lucium roseum* breed, but it has been superseded by *Christine*. There is, however, a variety partaking a little of the *Nosegay* section called *Hendersoni nana* which has its admirers, but unless for some special purpose I could never see any particular merit in it.

Skeltoni.—Horseshoe-marked; more upright grower than those I have named; but, on the other hand, the flowers are less showy. It is fast falling into disuse.

Kingsbury Pet..—Better than the last, but in the same strain. It is better as a potted plant than as a bedder.

(To be continued.)

J. ROBSON.

DECORATION OF THE FLOWER GARDEN IN WINTER AND SPRING.

GARDENS gay with flowers, and interesting with foliage, are not common at these seasons, nor is that to be wondered at, considering the present rage for polychrome gardens. Quarries contribute their sands and crystals, furnaces their clinkers, and some old building its quota of the elements necessary to form the brick-and-mortar gardens; but all these offer no compensation for the absence of the ever beautiful forms of vegetable life, whether in flower or not.

Any one visiting the gardens at South Kensington during the next six months, will not fail to notice that shrubs will not grow, no one can tell why, and that the polychrome-beds with their varied-coloured earthy substances are not in keeping with the order of a garden in the ensuing two seasons of the year—winter and spring. Such mimic gardens would be more in place as floors to playgrounds, on which are played all kinds of pretty games; but to the horticulturist they are too puerile to afford any amount of lasting gratification.

That there are plants sufficient to render our gardens not only interesting, but beautiful in winter and spring, the spring garden at Cliveden exists as a witness; for there it is questionable whether a finer display of flowers artistically arranged is not attained in April, and onwards to June, than at a more advanced period of the year.

But if we would see anything really worth seeing in the way of flowers during the spring and early summer months, it is not in the gardens of the great that we must look for it, but in those of the good rector over the way, or within the limited area of a cottage garden, where old tried friends have not been discarded to make way for those changeable things that are here to day and gone on the morrow. We cannot leave such places without saying with the poet—

"Full many a flower is born to blush unseen."

And so they are in their native wilds, and it is for man to bring them together so that they may form what we recognise as a garden having its flowers at all seasons, not those which flower in summer only, but those especially

"That come before the swallow dares, and take
The winds of March with beauty."

It is the absence of those plants which tend to enliven the flower garden between the removal and reappearance of the summer occupants of the beds, in addition to the labour and cost attendant on what affords a short display of bloom in summer only; and the anything-but-garden-like appearance of places where the bedding-out of tender plants is indulged in, that has led some to advocate a return to the old herbaceous border, and dependance upon a few showy annuals for the summer and autumn display. It is when there is an absence of plants flowering in spring that we may say of our present style of flower gardening, that it is

"—like the tyrannous breathing of the north,
Shakes all our buds from growing."

That the arrangement of tender plants in beds need not prevent any from enjoying flowers in spring, I hope to be able to show; and I am persuaded I can point out to the brick-and-mortar gardener, that there is no necessity to hunt quarry, coal pit, or furnace for materials wherewith to embellish our gardens during the winter, spring, and early summer months.

First amongst those adapted for rendering a garden interesting in winter, are evergreen shrubs. It is a common supposition that these must be grown in pots, but it was pointed out by the late Mr. Beaton, in Vol. XXII., page 59, that they would bear removal twice annually with greater facility than the summer occupants of beds—that is, they may be removed from the reserve to the places assigned for them in the flower garden in autumn, and again taken up to make room for bedders; the expense of providing suitable

evergreens in pots ready to put in on the removal of the plants in autumn, is therefore done away with. There is no difficulty either in growing them in pots, or removing them twice annually—first in October, and a second time in the latter part of May. It is the same with deciduous shrubs, they will move as well in October to their winter quarters, and in spring after blooming, if care be taken to preserve a ball. There is some difficulty, it is true, at the commencement, but the shrubs take amazingly well to the system after having been removed twice annually for a year or two. Shrubs of all kinds are now cheap, and can be had by the dozen, hundred, or thousand, of a suitable size; and those who intend doing something this winter towards improving the bare appearance of their gardens should set about it at once, and select a sufficiency of shrubs of various heights and shapes, distinct in foliage, both as regards colour and habit. The tallest should not exceed 3 or 4 feet in height; and three sizes or heights should be secured—viz., from 3 to 4 feet, from 2 feet to 2 feet 6 inches, and from 1 foot to 1 foot 6 inches; likewise different forms—i.e., pyramids and bushes, both feathered to the ground, and standards, also such as are naturally of low or prostrate growth.

The following list may serve as a beginning:—

Holly (*Ilex*), of many kinds, is admirable for the purpose, and though considered difficult of removal, no shrubs move more safely. They may be had of all sizes up to 3 feet, and of pyramidal and bush forms. By removing them so frequently they arrive at an early maturity, and produce berries when very small, and such plants are quite charming for the ornamentation of beds in winter. Besides, removing them twice annually renders the amount of cutting to keep them in shape a question of little import, it being only necessary to stop all growths at the fourth leaf, but only those that grow a-head of their neighbours.

Ilex aquifolium *flavum*, deep green foliage; *aureo-marginatum* (gold-edged); *senescenti-marginatum* (spineless gold); *spino-marginatum* (prickly gold); *croceo-marginatum* (gold-edged, but deep); *medio-pictum* (gold-blotted); *croceo-fuscum* (chimney sweep); *argenteo marginatum* (silver-edged); and its varieties *senescens* (spineless silver); *spinescens* (prickly silver); *latum* (broad-leaved silver); and *medio-argenteum* (silver-blotted). Then we have the small dense-leaved hedgehogs, *ferox* (green-leaved); gold variegated (*ferox aureum*); and silver hedgehog (*ferox argenteum*); the lovely *Handsworthi*, and its variegated variety; *cornuta*, *Tarago*, *Shepherdii*, *maderensis*, and its variety *atrovirens*; and last in my list, but not in merit, the beautiful Weeping Holly (*Ilex aquifolium pendulum*), which is quite charming on a four-feet stem, and so I think will be its variegated variety.

Then we have *Aucuba japonica*, and *A. lati-maculata*, which move as freely as Cabbages, and with far more certainty, giving material for a couple of beds of the loveliest kind, the bold, dense, and handsome gold foliage, though green at a distance, yet forming a suitable contrast to that of a deeper hue; and when we have the female *Aucuba* at a price within the reach of all, with its fine berries to set off its handsome foliage to better advantage, we may count on having three of the best shrubs for winter decoration in the *Aucuba*.

Common Laurel affords charming, bold, light green foliage, and when moved frequently it will transplant as safely in the last week in May as in the beginning of October, and as we want to move it at both these times, it is just the sort of plant. Its cousin, the *Portugal Laurel*, is rather more shy, but we must have it as dwarf bushes to form a centre for a large bed, and we will edge it with *Vinca minor* fol. *aureo-variegatis*. We must have our standard Bay trees, too; but as Bay trees are not over-hardy, we will have the *Portugal Laurel* instead; and having them on four-feet stems, all that is wanting to make people believe that they are Orange trees out of doors in winter, is that the green of the foliage is too deep by half. These placed in the spots usually assigned to Roses by the sides of walks, are far superior to the queen of flowers from October to June. They are very handsome.

Finely contrasting with these are standard *Yews*, which move like Docks. They will bear comparison with anything that a sunnier clime can send against them, even if left over summer, and dwarf plants of *Taxus baccata* are not amiss

for a distinguished position. The Weeping Yew (*T. Dovastonii*) is never seen to such advantage as when on a stem 4 feet or more high; and when we get its variegated offspring (*aureo-variegata*) on a stem suitable for a standard, we shall be in a way to show admirers things as they ought to be. *Taxus adpressa* or *brevifolia*, when once of a suitable size will last for nearly a generation without any cutting or clipping, and not become too large. We must also have the Irish Yew (*Taxus hibernica*), which always keeps mounting up, and never grows to one side, and its silver and gold variegated varieties.

Of Junipers, *Juniperus Bedfordiana*, *glauca*, *recurva*, *suecica*, and *thunifera*, are not amiss, and moving well, and having fine foliage we must have them. Nor must we overlook *Sabina* (Savin), its variety *tamariscifolia*, and its sub-variety *variegata*, for any of them make nice beds, and will answer for edgings; but a better kind for such a purpose is *prostrata*; while *J. stricta* is the most ornamental of all.

Thuja aurea, than which nothing can be more beautiful in spring with the golden colour it then assumes, and the American, Chinese, and Siberian Arbor Vitæs hold their own in any company with which they are associated. The best form of the Chinese Arbor Vitæ (*Thuja orientalis*), is *compacta*, nothing more than a close-growing variety of the species. *T. Hookeriana*, much resembling *T. aurea*, but more glaucous in appearance, is fine. *T. occidentalis* (American Arbor Vitæ), is one of the best, as it bears clipping well, and makes one of the most beautiful edgings and hedges known. The variegated forms of *T. plicata* and *T. orientalis*, both the silver and gold, are lovely for edgings to any of the species. *T. Wareana* is very fine, and by far the best of the Siberian Arbor Vitæs.

Of Cupressus, the most beautiful of all is *Lawsoniana*, forming a bed of the loveliest description; but beautiful as it is, it is as nothing when placed beside its variety, *aureo-variegata*, which is most attractively variegated with gold. *C. Lambertiana* or *macrocarpa* is just passable; and the same may be said of *McNabiana* and *Goveniana*. *C. cashmeriana* is a very graceful species, but I fear too tender for general adoption.

Chamaecyparis sphaeroidea variegata has handsome foliage, beautifully variegated green and gold. *Chamaecyparis thunifera* is handsome in a young state, and when kept low by frequent removal, but declines in beauty I think as a specimen.

Cryptomeria japonica nana and its variety *viridis*, offer a fitting contrast to foliage of a deeper green, and they have the rare property of retaining their bright olive green through the winter, which the species seldom does.

Some of the Pinuses are also useful, the very dwarf and close-habited *Abies clanbrasiliana* being admirable for edgings to large groups of deeper-hued foliage. *P. cembra* is very hardy and makes a good bed or a line in a ribbon-border. *Picea Nordmanniana* is the best of all the Silver Firs, and a specimen of this in the centre of a bed with a band of *Arabis caucasica variegata*, or *A. lucida variegata* of some, is beautiful beyond description. The dense habit of the Pine, and the foliage, dark green above, and of a beautiful glaucous hue beneath, make the golden *Arabis* appear to much advantage. The *Arabis*, by the way, is one of the best golden edging plants we have, and I was glad to see Mr. Thomson's notice of it in the Number for October 4th. *P. nobilis* is also fine, and few exceed it in beauty as a single specimen. Small plants of *Abies canadensis* (Hemlock Spruce), and of *A. taxifolia* (Californian Hemlock Spruce), a more ornamental variety than the preceding, which it much resembles, are useful. The majority of the Pinus family may be employed with good effect, but they move very indifferently, and as growing them in pots ruins them for after-planting to attain large dimensions, and as they are impatient of cutting, it is advisable to grow them in pots, and treat them in every way as dwarf plants, specially for decorative purposes in the flower garden.

Thujopsis dolabrata and its beautiful variegated form, are amongst the finest of recently introduced plants, and whilst they are growing to a size suitable for planting, it is worthy of consideration whether these and many others of a similar kind might not be advantageously employed for enlivening the dreary flower garden in winter. Nurserymen

should have them planted in groups so that visitors may see and judge for themselves, and I am certain that if this were done the taste for ornamental shrubs and trees would be diffused, and a zest given to the study of foliage, and its contrasts both in colour and outline, with a view to producing an effective arrangement, which can only be achieved by commencing on a preconceived design. I hope that we shall yet see nurserymen arranging their plants for sale, so that purchasers may at once select the most suitable for their purpose, creating at the same time a taste for arboriculture, which is, perhaps, the most neglected of all branches of horticultural science.

Retinospora pisifera aurea, than which nothing can be more lovely, and *R. obtusa*, are plants that must find their way everywhere; and when we have the dwarf *Thujopsis latevirens* and *Thuja pygmaea* at a price within the reach of all we may consider that we have as fine a lot of shrubs suitable for planting in beds in autumn as can be wished.

In addition to the above, I must name the beautiful *Ligustrum glabrum aureo-variegatum*, *L. japonicum aureo-margatum*, two beautiful forms of Japanese Privet which may be clipped into any shape and make; and *Osmanthus ilicifolius variegatus*, and its dwarf form.

Various kinds of Box are excellent as edgings, for forming even surfaces either all green, or silver or gold variegated. They may also be employed as bushes and pyramids. *Buxus rosmarinifolia*, *marginata*, *balearica*, and *halepensis* are admirable for decorative purposes.

Ivies, plain and variegated-leaved, and the different Periwinkles, come in as edging plants of no mean order.

The first step is to have a plan taken of the garden, numbering all the beds, and then to decide on those to be filled with evergreens, which should be about one-third of the whole. This will leave one-third for flowering shrubs, evergreen or deciduous; and one-third for dwarf flowering plants and bulbs. When this is done and the arrangement decided on, it is very easy to fill the beds satisfactorily from the stock of most nurserymen, for there are thousands of plants in every nursery that only need seeing to be called into requisition.

The next procedure is forking over the beds deeply; and the shrubs, which should be taken up with balls, must be planted at such distances as to cover the whole of the surface, placing the tallest in the centre, and edging each with some plant of dwarf habit, distinct in colour of foliage and character. After planting give a good watering, and if dry weather continue give occasional waterings afterwards; but if wet none will be required. Beyond this the plants will need no further care until spring, when they must not be allowed to suffer from want of water, and when the time for moving arrives, which may be the last week in May, take them up with balls of earth and plant immediately in the places assigned to them in any open yet sheltered situation, placing them so that each will receive light and air from all points, for no good comes of huddling them together. Water freely at planting and throughout the summer; a mulching an inch or two thick will save much of the watering by diminishing the evaporation from the surface. If any trimming be needed it should be done when the shrubs are growing, stopping the gross, and cutting-in the lanky growths, so that even nicely balanced specimens may be obtained. Further than this they need little attention, and will move again to the beds in October and November as freely as any other kind of plants, if care be taken to preserve a ball of earth at the roots.

To prevent any fear as to the liability to injury consequent on the removal of the shrubs twice annually, all of them may be grown in pots, using a rather stiff turf loam, and pots large enough to contain the roots comfortably. Drain efficiently, pot rather firmly, and giving a good watering plunge in the beds to a depth sufficient to hide the rims of the pots. In dry weather they must be watered, and after they are removed from the beds they should only be plunged to a depth sufficient to hide the pots, leaving the surface bare so that it may be known when any plant needs watering without the foliage indicating its absence. They should be annually freed of all roots that have penetrated into the soil through the holes in the pot, and potted every other year in October.—G. ABBEY.

(To be continued).

ORCHARD-HOUSE TREES.

I AM quite sure I go with a large proportion of your readers when I thank the "POOR GENTLEMAN" for his very agreeable letter and gentle castigation. He has given us only a portion of the rock on which he foundered by carrying too much sail. I read in the "Orchard-House," in all the editions from the 6th to the 11th—in the latter at page 50, under "Apricot culture," as follows: "While in their young state the fruit must be thinned, leaving at first upon a bush that has been two years in a pot about three dozen, which, when they attain the size of a small nutmeg, must be reduced to two dozen. The third year a tree, if it has prospered, will be able to bring three dozen to maturity. It is, however, better to have a few finely grown fruit than many that are small." This should have acted as a corrective; but I erred in trusting to the judgment of my readers, and hoping for some discrimination in them. I have since for some time found out that in describing modes of culture every sentence must be well weighed, allowing of no deviation from the prescribed mode; if you do, you are, as the boys say, "done."

Now for my confession. I confess that all the time I was writing the above paragraph I was thinking of a tree two or three years old *from the nursery*, so that the second year in the hands of the cultivator it would be from four to five years old, and quite capable, if well fed, of bearing three dozen of fair-sized fruit. I have just looked at a Peach tree five years old, and bearing thirty-four fair-sized Peaches; but the tree has had rich surface-dressings, and is a sturdy fellow, its branches 3 feet across. Under ordinary treatment two dozen would have been nearer the mark. My caution is a salve to my conscience; but I shall for the future be more strict in giving rules for thinning. Mr. Berger's orchard-house I know to be a great success. The unnecessary points in his culture are roof-ventilation and repotting in autumn—a troublesome business. I have never deviated from the easy and simple mode of culture I at first pointed out—viz., top-dressing in October by taking out the surface earth and effete masses of fibrous roots from 4 to 5 inches deep, and replacing with some rich compost of loam and rotten dung in equal parts. This fresh food in autumn, and surface-dressings in May, June, and July, of horse-droppings and malt dust, equal quantities mixed and saturated with strong liquid manure, seem, if we may judge from the luxuriant health of every tree to which they have been applied, to be perfect as tree food can be. It is indeed quite interesting to observe the seeming instinct with which the small feeding roots come to the surface for their rich food: no turtle-eating alderman could select and eat green fat with more avidity. On looking over my trees the other day I was half inclined, in a flight of fancy, to endue them with reasoning powers, and to conclude that they must have had a meeting, and passed a resolution to the effect that while such rich surface food was comestible they would not go down for any cold, watery, flavourless eating and drinking; for on looking at many hundreds of Peach and Apricot trees full of luxuriant health, I could not find any roots making their way through the apertures at the bottoms of the pots—all were at the surface.

I observe that Mr. Fish plunges his pots. In the light sandy soils of Bedfordshire I have seen pots plunged about two-thirds of their depth with good effect. In stiff soils they are better on the surface. The warm air of the house is like a blanket round the pots, and the roots feel it and enjoy it. I repeat, feed from above in preference to feeding from below; the food is warmer and more easily digested. I have always thought this to a certain extent, but have waited and watched, and now I know it. I also repeat—referring to the trouble that Mr. Fish takes in repotting his trees—that after a tree has grown in a thirteen-inch pot (it is always better to give inches in naming the sizes of pots rather than the pot-makers' terms, as 4's and 6's, to designate sizes), for three or four years, it may be at once transferred to an eighteen-inch pot (18 inches in diameter), which, as far as I can see at present, is the maximum size to be used in orchard-house culture. When established in pots of that size the roots at bottom may remain undisturbed; top-dressing in autumn, and surface-dressing in spring and summer, will keep the tree in luxuriant health

for many, many years. I often wonder what crinkum-crankum shapes the bottom roots of my old trees have assumed—I have not seen them for years.

The amateur orchard-house cultivator should not be oppressed with the weighty cares of repotting; it only troubles him to no purpose. A large tree in a large pot should be a pleasant fixture, requiring, like a very old and well-polished mahogany table, but little care to keep it bright.

The "Singleton Fig" is a misnomer. Its new name was given to it, I believe, by mistake, although it made it more commercially valuable, for trees of it were sold at 10s. 6d., whereas under its true name of White Ischia it was not so dear. No Fig better deserves culture, but only in the forcing-house, for it invariably drops its first crop, which should ripen in May with others when forced; but its second most abundant crop, which it should ripen in July, amply compensates, for no Fig can be more rich and delicious.

One more paragraph and I have done. I have seen spring surface-dressings applied by awkward gardeners so rough, so uncouth, so unlike what they should be, that I have felt a wish to toss pots and trees into some dark and swollen Lethe-like river. The surface-dressings to which I allude are great lumps of manure, undecomposed, and unfit for any place but the dunghill, heaped on the mould in the pot to a depth of several inches. This covering most effectually keeps out heat from the surface roots, the earth becomes sodden, the leaves turn yellow, the fruit drops, and the wise operator opens his mouth and wonders what can be the matter.

If my favourite compost for surface-dressing cannot easily be procured, the best substitute is rotten or nearly rotten manure chopped up into a neat-looking and friable state. It should next be saturated with strong liquid manure for two or three days, and then used—not piled on 5 or 6 inches deep; the depth should be from 2 to 3 inches—formed into a neat shallow basin, the stem of the tree in the centre, so that the water given should be retained.—T. R.

SUGGESTIONS CONCERNING PROVINCIAL HORTICULTURAL SHOWS.

THE "Secretary of a Country Horticultural Show of thirty years standing" asks our opinion on the proper time to hold a show. That of the past season, he says, was held in the last week in September, which was thought by many to be too late. He adds, the accommodation for the show in a public hall in the town is very good, and the competition amongst exhibitors is great, cottagers also being favoured with a class. From the inquiry made we suppose the managers of the show would like to have it at a time likely to bring together the greatest number of important products. Although he mentions Dahlias, Hollyhocks, and Gladioli as being favourites in the neighbourhood, we apprehend the period that would bring the greatest number of attractive objects to the show would be the one selected.

Now, it is by no means easy to give good advice in a case like the above without more knowledge of the district than we possess. Very often the best time to hold a show is one in which horticulture is very little consulted; the fashionable season at a watering place, or any event in a county or district town calling a number of people to it, is often made the time for a horticultural show. Visitors at such places, more especially when the funds in a great measure depend on what is taken at the door, are more consulted than any particular class of plants, fruits, or vegetables. The latter have to be got ready for the show-day, not the show-day for them. This state of things cannot be altered, neither is it fair to find fault with it; but we will suppose that the show in question is not fettered by any conditions of the above kind, but simply that the good people of a quiet country town want to know when is the best time to insure a good and attractive show, regardless of all outside influences. Although we are quite at sea where our correspondent writes from, we will suppose him to reside somewhere to the south of York, and point out one or two modes of dealing with the show, so as to meet the requirements of the majority of those interested in the matter. That it is impossible to satisfy all must be known to every one

who takes upon himself the duty of secretary. By way of assisting the inquirer we will state a few facts connected with a local horticultural show of about the same standing as the one alluded to, but which was, perhaps, at one time at least, in a more prosperous condition, and its operations more extended. Examples are always good monitors, and we give this one before venturing an opinion.

The horticultural society alluded to is connected with a town of some 25,000 inhabitants in a rural but somewhat wealthy neighbourhood, and not a hundred miles from London. Most of the leading gentry and principal tradesmen of the town and neighbourhood are members paying one guinea annually, for which they have four tickets of admission to each show, there being two in a year. Gardeners pay 5s. subscription, which by a defect in the administration merely allows them two tickets to each show. The funds are also augmented by payments at the doors, visitors at an early hour being charged 2s. 6d., and later in the day 1s. The first and most important show is held in the last week in June, under canvas, in a field commanding one of the finest prospects in England, there being at least half a dozen large tents, with two military bands, and all the pomp of a metropolitan show; and if the day proves fine it is so well attended that, notwithstanding the tickets of subscribers, a sum of upwards of £100 has frequently been taken for admission. The second show is generally in the first week in September, and is held in the public hall or market-room—a spacious room, in which it has been said that six hundred have dined. The September show is more for fruit than plants; but there are the cut flowers of various kinds, with vegetables of almost every description; and as an exhibition of horticultural produce and skill it is far superior to the June show, but never so attractive. Fashionable visitors like more space, and, consequently, attend in less numbers, so that in the most successful days the payments for admission bring but a small sum to the exchequer, and this show, as compared with the June one, is a dead loss to the Society. The prizes are not large at either of the shows, but the varied productions make up a considerable display, and the June show is looked upon in the neighbourhood as a fête at which the best articles of attire are brought forth. Now, this Society, like all others, has been liable to the visitations common to such institutions—one or two unfortunate days, and a change of place for holding the show, coupled with, perhaps, the fact that its novelty is wearing off, has much impaired its position, so that, instead of having a considerable sum in hand, the Society is, or was very lately, on the verge of insolvency, not from any want of care or mismanagement of its affairs, but solely from the misfortunes which such institutions are liable to.

With a case like this before us, we confess feeling some hesitation in giving advice; but as our correspondent's query simply relates to the best time to hold one show, the matter is circumscribed, still our answer must be a qualified one. If the show be for plants, or if they are regarded as of more consequence than fruits, June is the best time, and not too late in the month. If, however, forced fruits, in addition to plants, be in requisition, the last week in June will in a great measure answer for both, as by that time Grapes, Melons, and possibly Peaches and Nectarines, may be forthcoming, with Cherries and Strawberries from out of doors, and a host of vegetables and plants of the finest description. If an extended show of fruit and cut flowers be the desideratum, the first week in September will generally furnish both; but, as stated at the beginning of this article, if the company is likely to be greater in June than in September, let the fact have due weight in the decision, as no show, nor in fact anything else, can well go on without visitors. In most cases an energetic secretary, and half a dozen active business committee-men, having a perfect knowledge of the feelings and requirements of the neighbourhood, are able to judge whether it is prudent to make a bold move in a progressive direction or not. If your Society has existed thirty years, and is still popular, there is proof that the principle is healthy, and that a more liberal course might be ventured upon with advantage. Although we would strongly advocate the increase of prizes, and the encouragement of horticulture, we are not blind to the fact that the public at large look also at some other source of amusements as being necessary adjuncts to such a

meeting, and these are expensive items. The hire of half a dozen large tents or marqueses will cost from £20 to £30, perhaps, and music is also costly; added to which the hire of seats, the payment of assistants, and other charges, trench heavily on the funds; but it sometimes happens that a bold move in this direction is successful. The advisability of changing the established head-quarters in the Market Hall, to a place out of doors, is a subject that can only be judged of by those well acquainted with the neighbourhood, but it is very possible it might succeed. A spirited attempt is often followed by success, and the projectors receive their meed of public approbation. If an out-door exhibition be decided on, then by all means have it in the end of June or beginning of July, if the situation is late; the length of the days and other things favouring out-door amusements at that time more than at a later period. By well considering all the arrangements beforehand, and perhaps revising the schedule, or in fact making a fresh one, a feature may be given to the show which it has never yet had. It might also be announced, if the June show were successful, and the funds of the Society would afford it, that a second would be held in September for fruits and cut flowers, &c., as at present; this show, of course, being held in the market-room. For such a show we should say that about the 10th of September is a good time, as Peaches and Nectarines would then be ripe; the end of that month is too late for them. It may be thought that the interval between the two shows is too great, but the public do not like too frequent repetitions, and July and August do not present much that is important beyond what may have good representatives at one or other of the shows here recommended. As the show is well supported by exhibitors, it is very likely that a spirited move in the way suggested will meet the support of the public, and that the local press will have the opportunity of recording a complete success, everybody being pleased with the affair, and that thousands of visitors will retire to their homes with the remembrance of a social and intellectual treat, which such meetings afford. We have little hesitation in recommending a June show; but in the event of such not being decided on our ignorance of the locality and its peculiarities prevents our giving an opinion on the subject of the show being held either out-doors or in. We would have the September one as early as convenient, but generally about the 10th will be found the best time.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 11TH.

FLORAL COMMITTEE.—The scarcity of plants and flowers sent for the examination of the Committee this day fully realised the fact of the departure of sunny days and beautiful flowers; but we have no reason for complaint. The interesting meetings held by the Committee during the past season, and the number of plants and florists' flowers that have been examined, fully prove that a deep and lively interest in horticulture still exists. George Cooper Esq., Alpha House, Coburg Road, exhibited a small plant of an Oncidium from Brazil. It was recognised as a well-known variety. Mr. Legge, Edmonton, sent three seedling Dahlias—Lord Warden, deep orange red, tipped with white; Mr. Bolton, dark lilac rose; and Lightning, yellowish buff striped with red, of good form. This latter seedling received a second-class certificate.

From Mr. Bull, Chelsea, came three very pretty and interesting varieties of British Ferns—*Polystichum angulare rotundatum*, *Polystichum angulare grandiceps*, and a form of *Athyrium Filix-femina*; but the plants were too young to decide upon their merits, though they are all of them excellent varieties. *Aucuba japonica picta* (mas), in flower, a very beautiful variety with broad white variegation, received a first-class certificate, and *Aucuba japonica vera* was also shown with two clusters of its brilliant red berries. Mr. Macintosh, Hammersmith, sent *Solanum capsicastrum hybridum*, a cross between *S. capsicastrum* and *S. pseudocapsicum*; it will form a nice plant, intermediate in size and habit between its parents—second-class certificate. Mr. Macintosh also had a seedling *Capsicum* with round seed-vessels the size of marbles.

Messrs. Stuart & Mein exhibited cut specimens of seedling Pentstemons and Antirrhinums, some of the latter good flowers, but not an advance on varieties in cultivation. Messrs. Veitch, Chelsea, sent three seedling Cattleyas of much interest—*C. devoniensis*, white narrow petals, with deep purple lip—first-class certificate; *Cattleya Dominiana alba*, a white variety of *C. Dominiana*—first-class certificate; and *Cattleya exoniensis*, a beautiful variety, which received a first-class certificate at the last meeting of the Committee. Messrs. Henderson, Wellington Road, exhibited *Pelargonium Lady Cullum*, another variety of those beautifully variegated-coloured Zonale Geraniums, the introduction of which belongs solely to this well-known firm. *Lady Cullum* is distinct in colour, and equally beautiful with Mrs. Pollock, &c. It received a first-class certificate. Mrs. Gerard Leigh was a white-edged variety with a coloured zone, but inferior to *Italia Unita*. Mr. Fleming, Cliveden, brought cut specimens of several seedling Pelargoniums not yet named, they are of the intermediate section, having the truss of the Nosegay, but broader petals. Some of them are novel in colour, one being a bright orange scarlet, others deep purplish rose of varied shades. Next season these will probably appear with names, and will take a good position in that section of Pelargoniums which they represent.

VISITS TO GARDENS PUBLIC AND PRIVATE.

REED HALL, COLCHESTER, THE SEAT OF J. T. HEDGE, ESQ.

Has ever any Rose-grower had the homage paid to him that Mr. Hedge has? Have ever any others but he been asked where he was to exhibit, as the questioners would rather not enter into competition with him? Has ever any amateur held a more distinguished position as an exhibitor than he has done? Nay, is there any one, north, south, east, or west, who has the courage to pluck the laurels from him, or to deny him the place he has unquestionably won as the champion exhibitor amongst amateurs? Let us, then, take a peep at the garden from whence these achievements issue.

Reed Hall is an old manor house, about a mile and a half from the old Roman town of Colchester, and was so called (its original name being Foxborough), because until a late period it was thatched with reeds. There is nothing in the house itself to call for remark, and I daresay thousands might pass by and never so much as dream what marvels of skill are produced there. The situation is high; the soil deep, rich, unctuous loam, such as the Rose delights in; and the drainage excellent. Here are conditions to begin with sufficient to encourage a grower, but not sufficient in themselves to insure success. In such a soil the briar is at home, and the Manetti comparatively useless, so that Mr. Hedge mainly depends on the former for his stocks. And here let me say that he does not leave anything to chance work. When he wishes to get briars he does not buy them of those who go about for them, and perhaps have them for days or weeks out of the ground, but he goes or sends some of his men; and the briars are dug out, carried home, and planted at once, many of them in the situation where they are to remain; and on stocks so treated Teas, Noisettes, and Bourbons, as well as Hybrid Perpetuals, flourish with unwonted vigour. The Rose garden is arranged in beds; and as these are of a convenient size and of various forms, it is easy to go round them and examine every flower in the bed with great ease: this, I think, is a great recommendation. Here is a bed of Teas, and there a bed of Hybrid Perpetuals; and you can, moreover, see the names of them all, for Mr. Hedge is methodical to a degree in everything he does, and legible and accurate labelling is a matter on which he prides himself. Where there are standards the labels are attached to the trees; where dwarfs, pieces of slate—such pieces as are taken off by slaters, cut and prepared afterwards—are used; they will then last for years. In everything there is the greatest neatness; all his cards, shades, slates, &c., display this, which is a great charm in a garden, and always tends to set off flowers however good, while the very best flowers are spoiled by want of it.

I have said that he does not use the Manetti stock much, for he finds that it very soon, on such stiff soil, kills the Roses, so that they rarely last more than two years—in fact,

it is a stock adapted better for poorer and lighter soils, which can be highly manured. Mr. Hedge does not encourage autumn blooming. His object is to obtain flowers in the Rose season, and not afterwards, and hence he says that he prefers not to bleed his plants by shortening the shoots to procure an autumn bloom. Especially is this the case in a dry season like the present year. He says the plants require all the vigour they can for themselves, and therefore he would not allow even the blooms to be picked off.

With regard to the removing of Roses, he does this as a rule every three years, although some are left for five; but he considers that they ought to be removed every three years. By having his beds of different ages they are not all removed at the same time, and so great an amount of labour as that of replanting all his stock is avoided. What is the amount of this stock? will naturally be asked. Well, I believe not far short of 5000. But then these are not all planted out in beds. Many are in two large squares, while there is a large border of dwarfs containing some on the Manetti stock, which, as I have said, is but sparingly used. It is manifest that Mr. Hedge, having so large a stock, and budding a considerable quantity every year, from whence he can get maiden blooms, stands on a great vantage ground above common mortals. Any one who has noticed his stands must have remarked the splendour of the Teas and the variety in his boxes. To obtain the former great care is taken. He has a large stock of old parasols and umbrellas, and these are opened out over the trees as the buds are expanding, and they are thus preserved from the influence of the weather; and there, in that little sheltered corner of the house, is the Banksia, budded on which those wondrous blooms of L'Enfant Trouvé, Mr. Cant's Rose, are found—those glorious blooms, which have made many a Rose-grower open his eyes widely; in fact, everything that skill and experience can suggest has been done to make this a very paradise of Roses.

Mr. Hedge is no great lover of novelty. He waits to see a Rose well proved before he puts it down as A1; but such flowers as Charles Lefebvre, François Lacharme, Alfred de Rougemont, and Baron Adolphe de Rothschild he cannot do without, and when once he adopts a Rose he propagates it largely. Nor amongst the notabilities of his garden should I omit Walter, as good a judge of a Rose well nigh as his master, and as enthusiastic in bringing them out in good order for exhibition. Will not Walter sit in a luggage-van, all night if need be, so that the boxes shall not be capsized? Will he not regulate the pace of the van that takes them to the Palace or Kensington?—aye! will he not sit up five nights in the week when showing is in season, and more too if needed?

Nor are Roses the only things cultivated here. Here is a square of Dahlias from which grand blooms will be cut which shall carry off cups, and there some splendid Aster which shall take away first prizes too. Peep, too, into that greenhouse; see those pots of Japan Lilies. Did you ever see anything more full of bloom, or more densely packed than they are? Will they not astonish the Colchesterians next week at their flower show? (this was in August). And here are greenhouse plants well done and ready for the earlier shows next year; then in that cool viney see the magnificent Black Hamburgs, and even Muscats, lying in rich abundance; look even at the vegetable garden, and see the vigour of growth, and order, and regularity, and then say whether good gardening is not practically carried out. And now suppose that, having made your *petite tour*, you enter inside the hospitable walls of Reed Hall. Let me tell you, if you are not a teetotaller, that you will find there as good a glass of wine as is to be had in England, and that, whatever you are, you will get as hearty a welcome as is to be had from John o' Groat's to Land's End—aye, or even in the dear old green isle herself, around whose name cling many sweet and pleasant memories; and as you sit there listen to your host as he descants on Roses, their characters, their caprices, their triumphs; if no hairbreadth escapes by flood and field, there are midnight journeys by railways, and *contretemps* which it required a good courage to overcome. And then you may hear racy stories of the doings of the pompous officials of the Imperial Society of Toadyana, and of the brilliant offer of a 2s. 6d. prize for bringing up a box of Roses in September to, let us say, Timbuctoo; and

if you have your ears open and your wits about you, you may hear many a wrinkle that will be as gold to you by-and-by—at least this was my experience. I had no recommendation to Mr. Hedge but that I loved flowers and knew something about Roses; and yet I was treated with a hospitality so genial, and a courtesy so truly that of an old English gentleman, that amongst my sunny recollections I have to put down in the tablet of my memory my visit to Reed Hall.—D., *Deal*.

TRITOMA UVARIA CULTURE.

In your Number of October 4th, which has only just come under my eye, Mr. Robson asks for the practice of others in reference to this ornamental plant, and I willingly give the experience of an amateur in a small way.

The Tritomas are especial pets of mine, and I think I may claim success for them this year, inasmuch as the spikes have all been between 5 and 6 feet in height, the last fourteen inches being densely clothed with bloom, fully expanded to the very tips. The flower-stems began to shoot up in the beginning of August, and by the third week of that month were in all their glory. The plants have never been watered at any time during the season; and my own idea is that the peculiar nature of the soil, which is a pure loam, is in a double sense at the root of the matter. All bulbs, in fact, succeed well here, and Crocuses and Snowdrops are grown by the acre in this neighbourhood for the London market. A strong confirmation of this opinion I find in the fact that when I resided in Middlesex, the soil being a gravelly clay, the same plants never did well with me, showing blooms of only half the height, and often only in time to be nipped off by the frost before they expanded. As soon as I removed here and transplanted them into this soil all trouble to induce vigour ceased, the plants rapidly increased, and the flowers have always appeared some weeks earlier than before.

Some time ago it was recommended in this Journal never to meddle with their foliage. I have followed out this advice, and find serious injury always follows its infraction. This constitutes a great drawback to the ornamental character of the plant, as the long leaves look very untidy in the winter and spring. A plant that was "trimmed" a bit last autumn "to make it look tidy," as my man called it, before I had time to interfere, totally vanished in the winter, and a few suckers are all that is left of it now.

I usually protect them in the winter by a thick coat of fine ashes laid round the crowns. The variety *glaucescens* appears to be the most hardy here, and the flowers are brighter and more showy than the *grandiflora*, but the foliage being narrower gives a less graceful habit to the plant.—GEORGE F. BARRELL, *Spalding*.

SOME HARDY FERNS PREFER A HIGHER TEMPERATURE.

I LIVE in a land of Ferns, some, indeed most, of the varieties, British ones, being indigenous to this county. It may be interesting to other growers of Ferns to know that some species which are found in this county will thrive far more luxuriantly in the hothouse than in their own habitat. As to *Asplenium marinum*, I believe this is already known. On the seashore near this place it grows sparingly and with no great luxuriance. In the stove here it flourishes most luxuriantly. *Asplenium lanceolatum* is found in great abundance near Barmouth, in this county. In the stove its character is totally altered. Instead of being a small shrivelled plant, it grows with such luxuriance that at first sight it may be taken for *Asplenium adiantum nigrum*. *Lastrea recurva* grows equally well in the hothouse.

I may also mention *Asplenium septentrionale*. Till I introduced it into the stove I kept a plant for two years lingering during the winter with a frond or two. It is now looking healthy, with many fronds; and in the last month I obtained a healthy plant from Snowdon, which was potted, and placed near the other, and not a frond has changed its colour.

Of *Polystichum lonchitis* I cannot speak so favourably;

though we are on the west coast of Wales, it hitherto has not done well here. Last year it lived through the winter in a cold frame. I have tried it in the hothouse, it began to shrivel there. It does not succeed much better in the greenhouse. I am inclined next year to try it out of doors.

Woodsia ilvensis grows without any particular care in our fernery, which is under the shade of a large Beech tree.—

A FERN-GROWER, Peniarth, Merionethshire.

CONSEILLER DE LA COUR PEAR.

THE REV. S. Reynolds Hole, of Caunton Manor, near Newark, informs us that he has just weighed two fruit of that variety, and he wants to know "whether 18½ ozs is, or is not, an unusual weight for a delicious dessert Pear grown in a midland county;" to which we readily reply that it is an astonishing weight for this, or any other delicious dessert Pear. The greater experience we have of Conseiller de la Cour, or Maréchal de la Cour, as it is sometimes called, teaches us that it is not only one of the finest Pears in cultivation, but that it is one which does not confine its fine qualities to certain, or very highly favoured localities, but will succeed even in those districts where the choicest Pears are rarely to be met with in perfection.

MR. J. CATTELL'S NURSERY, WESTERHAM.

WHEREVER gardening is carried on with energy, combined with skill and careful management, there is much to see that is both interesting and pleasing, as well to the professional horticulturist as to the amateur. This is more particularly the case in extensive grounds, where, from the variety of subjects presented to notice, the ability of the cultivator is rendered more manifest. The perseverance of English gardeners is often a theme for eulogy, and we are all proud of their exploits, and, as Englishmen, we all love to praise and admire their achievements. Such was the pleasure I experienced on a visit to Mr. Cattell's nursery at the end of last month.

The nursery, situated on the north side of the town of Westerham, has been established many years, and is too well known to the horticultural world to need particular description. For the information of your readers it may be as well to state that it is easily reached from the Sevenoaks Station, a few miles to the east, or from the Caterham terminus by the omnibus, passing through the villages of Oxted and Limpsfield, just under the eastern portion of the ridge of the North Downs, one of the prettiest drives in the county of Surrey.

The premises have been greatly improved by the entire rebuilding of the seed warehouse, offices, shop, and residence, with a handsome frontage in the High Street of Westerham now in course of completion, and which will add greatly to the convenience of the establishment.

Passing through the building the visitor at once enters the nursery. The first object of attraction is a belt of Conifers, with some ornamental shrubs intermixed, on each side of the road leading to the lower part of the grounds. This plantation, which is of considerable length, contains all the varieties now ordinarily used for ornamental purposes, excepting the larger Pinuses, with many beautiful kinds of recent introduction. Being tastefully arranged, the view from the upper end is very striking; the more so at this time of year, when the diversity of the foliage of the coniferous tribe is seen to the best advantage; and, being interspersed with the variegated forms of the Holly, Box, Negundo, Syringa, the effect is considerably heightened. Among the Conifers are fine specimens of *Abies (Picea) nobilis*, *A. Nordmanniana*; *Cupressus Lawsoniana*, *C. macrocarpa*, *C. Goveniana*; *Thuja gigantea*, *T. aurea*; *Thujopsis borealis*; *Juniperus drupacea*, the curious *J. sphaerica*, *J. hibernica compressa*, a very diminutive form of the Irish Juniper; *Abies clanbrasiliana* and *A. pumæa*. The ground on each side of these belts is appropriated to seed-plots for kitchen garden plants, Strawberries, and some herbaceous and annual flowers.

Crossing the public road which divides the nursery, the principal compartment is entered containing the stock of American plants, a very complete collection in excellen-

condition, notwithstanding the long drought of the summer, which has seriously affected this class of plants in many parts of Surrey, and probably in other localities where the soil is not naturally adapted to them. Here were also the quarters for the Roses and the more choice ornamental shrubs, the orchard-house, propagating-houses, flower-beds, and the Dahlias, then in magnificent bloom.

Roses form an important branch of the business here, and have been successfully cultivated for many years, the stock numbering many thousands. To see one particular kind was the chief object of my visit. A new seedling raised by Mr. Cattell is being sent out this autumn for the first time it is named "Beauty of Westerham," and is one more instance that good Roses can be originated in this country. When I first saw a single bloom of it, now more than two years ago, in a box exhibited at the annual Show of the Blechingley and Nutfield Cottage Garden Society, in company with Victor Verdier, Senateur Vaisse, Madame Furtado, Louis XIV., Madame C. Crapelet, and others, then comparatively new Roses, it appeared a beautiful and distinct flower. I expressed my opinion of it at the time in another journal, and a further acquaintance with it gives me no reason to change my opinion. Its qualities may be thus summed up. As an English production it is well calculated to withstand the vicissitudes of our climate, being vigorous in habit, with bright green foliage, blooming freely all the season, delightfully fragrant, equalling in that respect Madame Furtado, and of a rich scarlet crimson colour. It will be said that we have enough crimson scarlet Roses; and all who have seen the noble blooms of Senateur Vaisse, Charles Lefebvre, Beauty of Waltham, Lord Clyde, Gloire de Santenay, Maurice Bernardin, Due de Rohan, and some others that have this year been produced and exhibited, must acknowledge that we are rich in this colour, yet Beauty of Westerham is distinct from any of the above varieties; and Mr. Cattell is quite justified in sending it out as a useful addition to our Hybrid Perpetual Roses.

Another novelty, of a very different nature from the preceding, is a *Tropaeolum* called Foxhunter, obtained by Mr. Farmer, the intelligent foreman, from T. Schultz. This will prove a very useful bedding plant, where masses of colour are sought for, being a most profuse-blooming kind, of a very brilliant scarlet. A peculiarity of this *Tropaeolum* is the sending out spurs 3 or 4 inches long at every joint along the stem, producing abundance of flowers. Mr. Farmer informed me that it is the freest-blooming *Tropaeolum* he has ever known. The foliage somewhat resembles the well-known Crystal Palace kind.

The fine weather previous to my visit had brought out the Dahlia blooms in great abundance and perfection. The large plot of ground planted with Dahlias afforded a splendid sight. Mr. Cattell is not unknown to fame in connection with this flower, having on several occasions boldly entered the lists with the Hector and Achilles of Dahlia growers from Slough and Salisbury.

Not being a connoisseur of Dahlias, I speak with diffidence about them. Of the great number of varieties, I could not but admire the large and magnificent blooms of Andrew Dodds, Midnight, and Triomphe de Pecq, among the dark kinds; Lord Palmerston, John Keynes, scarlet; Lord Derby, crimson; Queen, Golden Drop, and Goldfinder, primrose and yellow; Juno, lilac; Hon. Mrs. Trotter, Miss Pressley, and Charles Turner, mottled or tipped at the edges of the petals.

A walk through the orchard-house necessarily concluded my visit, for, although there was much more to see, my time was limited. This orchard-house is what I have been taught in the columns of this Journal an orchard-house ought to be—viz., a simple wood-and-glass structure to protect fruit trees from the inclemencies of this variable climate, and to further the ripening of the fruit without the aid of artificial heat. Mr. Farmer informed me that the house in question fully answered the purpose it was intended for. His explanation was very simple. The trees which are all in pots are brought into the house in February, when the sap generally begins to rise. After they have fruited, and the young wood is thoroughly ripened, they are brought out and fully exposed during the winter. On their treatment while under cover it is no part of mine to enter, not pretending to sufficient acquaintance with the subject further than the

common attribute of most of us, that we cannot help believing what we see. Judging from the superb fruit on the trees in that orchard-house, it seemed to me marvellous that there should be any controversy at all upon the subject.

Among the ornamental shrubs I noticed the interesting *Colletia bictonensis*, *Desfontainia spinosa*, both of which have proved hardy with me, and the latter bloomed well; *Griselinia littoralis*, recommended by Mr. Robson, and very properly; the curious *Rubus leucodermis*, and *Cotoneaster Simonsii*, with its bright scarlet berries, which render it very ornamental in winter.—ADOLPHUS H. KENT, Blechingley, Surrey.

PEARS ON QUINCE STOCKS IN A LIGHT SOIL.

In your last Number of the Journal I observe in your answer to "YORKSHIRE" that you recommend him to procure Pear trees on the free stock, on account of the dry porous nature of his subsoil.

I live in a more cold and bleak portion of Yorkshire than Doncaster and its neighbourhood. My garden is on a light dry limestone soil overlying a limestone gravelly subsoil. In this soil I have grown a number of Pear trees on the quince stock for the last twelve years. My collection consists at present of forty-eight Pear trees, of which seventeen are dwarf bushes. With two exceptions they are all on the quince stock, and these two have given me more trouble with a less satisfactory result than a dozen of the others on the quince. All my trees are in perfect health, and in admirable order. I simply state this to show you that I know something of the subject on which I am writing.

From my own experience I would most decidedly recommend "YORKSHIRE" to purchase bush or pyramidal Pear trees on the quince stock. The list of Pear trees extracted from Mr. Rivers's "Miniature Fruit Garden" contains several varieties not suitable to the climate of Doncaster, unless they be grown against a south or south-west wall. I should recommend the following Pears as much more likely to succeed as bushes or pyramids:—*Doyenné d'Eté*, August, on quince; *Jargonelle*, August, ditto; *Beurré Giffard*, September, ditto; *Beurré Goubauld*, October, early, ditto; *Beurré Superfin*, October, ditto; *Louise Bonne of Jersey*, middle of October, ditto; *Comte de Lamy*, ditto, ditto; *Fondante d'Automne*, ditto, ditto; *Thompson's*, ditto, ditto; *Beurré Diel*, ditto, ditto; *Seckle* and *Suffolk Thorn* on the free stock.

If "YORKSHIRE's" garden is not well sheltered from the prevailing winds it would be desirable to procure bush-pruned Pear trees, otherwise the pyramidal form of training is to be preferred.

I like trees grown in the south the best, as their wood is always well ripened.—C. M., Yorkshire.

[We are much obliged by this communication. It is evident that on some dry soils in certain localities the quince stock succeeds; but on light soils Mr. Rivers recommends that the soil over the roots of the quince stocks be mulched, and the junction of the stock and scion covered with earth, we presume to encourage the production of roots from the latter. On a light soil with a chalky subsoil the only trees that failed in our orchard were those on quince stocks.]

ORCHARD-HOUSE AT GREAT MARLOW.

REFERRING to "J. F.'s" account of the orchard-house at Great Marlow (No. 183, page 256), I shall feel much obliged if you will state the numbers of each sort of fruit tree in the house, that some idea may be formed of the yield. The average which he gives is no criterion.—DAVID B. LINDSAY.

[The following is a list of the trees, and the number of each variety:—*Pears*.—*Easter Beurré*, 2; *Winter Nelis*, 2; *Fondante d'Automne*, 2; *Marie Louise*, 1; *Colmar d'Aremberg*, 2; *Beurré Rance*, 2; *Passe Colmar*, 1; *Josephine de Malines*, 1; *Fladberg*, 3; *Beurré Superfin*, 1; *Bergamotte Esperen*, 1; *Beurré Diel*, 1; *Louise Bonne of Jersey*, 1; *Van Mons Léon le Clerc*, 2; *Brown Beurré*, 1; *Napoleon*, 1; *Glou Morceau*, 2.—Total, 26. *Apples*.—*Mannington's Pearmain*, 1; *Reinette du Canada*, 2; *Court-Pendu-Plat*, 1; *Celldini*, 2; *Cox's Orange Pippin*, 3; *Ribston Pippin*, 2; *Old Nonpareil*, 1; *Emperor Alexander*, 1; *Scarlet Pearmain*, 1; *Golden Pippin*, 2; *Northern Spy*, 1; *Melon Apple*, 3; *Male*

Carle, 1; *Scarlet Nonpareil*, 1; *Boston Russet*, 2; *Court of Wick*, 1; *Cockle Pippin*, 1; *Wheeler's Russet*, 1; *New Rock Pippin*, 1; *King Pippin*, 1.—Total, 29. *Peaches*.—*Salway*, 2; *Royal George*, 3; *Barrington*, 2; *Grosse Migonne*, 2; *Early York*, 1; *Violette Hâtive*, 1; *Noblesse*, 1; *French Galande*, 1; *Belle Bauche*, 1; *Walburton Admirable*, 1; *Bellegarde*, 1.—Total, 16. *Apricots*.—*St. Ambroise*, 2; *Moorpark*, 7; *Peach Apricot*, 5.—Total, 14. *Plums*.—*Kirke's*, 2; *Jefferson*, 1; *Late Orleans*, 2; *Reine Claude de Bavay*, 2; *Pond's Seedling*, 2; *Coe's Golden Drop*, 2; *Impératrice*, 1; *Transparent Gage*, 2; *White Magnum Bonum*, 2; *Cloth of Gold*, 2; *Guthrie's Late Green*, 1; *July Green Gage*, 1; *Early Prolific*, 1.—Total, 21. *Nectarines*.—*Elrige*, 2; *Rivers's Orange*, 2; *White*, 4; *Hardwicke Seedling*, 2; *Violette Hâtive*, 2; *Balgowan*, 2; *Bowden*, 1; *Pitmaston Orange*, 1.—Total, 16. *Cherries*.—*Empress Eugénie*, 1; *Cleveland Bigarreau*, 1; *Black Eagle*, 2; *Waterloo*, 1; *Governor Wood*, 6; *Royal Duke*, 1; *Circassian*, 1; *Brown's Black Heart*, 1; *Elton*, 1; *Werder's Early Black*, 1; *Florence*, 1; *Duchesse de Palauau*, 1; *Black Tartarian*, 1; *May Duke*, 1; *Belle Agathé*, 2.—Total, 22.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHEN Box-edgings require relaying, or walks gravelling, let it be done forthwith. *Beet*, the roots of the latest crop to be now taken up without being bruised and the tops carefully twisted off above the crown, to be stored away in any dry place free from frost in sand or earth, or buried in heaps of earth, as other roots are kept. *Broccoli*, it is now time to check that growing luxuriantly by laying it down. We find constant attention is necessary to secure the plantations of Cabbages, the Cauliflowers under hand-lights, and the winter Lettuces, from the ravages of slugs. Dust the ground between the plants every second day with soot and quicklime, and make good the blanks from the seed-beds. Where Carrots, Parsnips, Salsify, and Scorzonera, are liable to be attacked by grubs, which are very numerous this season, or to injury by frost in consequence of the situation, being low and damp, the sooner they are taken up and stored away the better.

FRUIT GARDEN.

The preparation of quarters for the reception of Gooseberries and Currants should be completed, as planting may shortly commence. The formation of fruit-tree borders should be proceeded with, and stagnant water must be carried off by drains. A stratum of stones or bricks should intervene between the soil of the border and a cold clayey bottom. Although these precautions may not be strictly necessary in all cases, there are but few instances where they can with propriety be dispensed with.

FLOWER GARDEN.

Some temporary coverings should now be at hand to protect half-hardy plants from the first attack of frost, which is generally of short duration, when a spell of fine weather succeeds. By such protection for a night or two their flowering season may be prolonged for a few weeks. Chrysanthemums against walls should be closely tacked in, and spare lights, reed-covers, or mats, kept in readiness to protect them from sharp frosts. A fresh, green, cheerful appearance may be given to the flower-beds as soon as the frost has done its worst amongst the bedded-out plants, by introducing a supply of small neat plants of the different dwarf hardy evergreen shrubs, such as *Aucubas*, *Berberis*, *Laurus-tinus*, *Arbor Vitea*, *Laurels*, and any of the many sorts of *Pinus*, *Rhododendron*, *Holly*, &c., to be kept in pots. By disposing of the various tints of green and variegated foliage in separate or mixed masses, a pleasing and interesting character could be given to the view of the flower garden from the windows even in the dull days of winter. Choice Alpines should be plunged in coal ashes or old tan. Place Carnations and Picotees in pots in cool frames, and water sparingly. Protect tender Chinese and Tea-scented Roses. Shrubs in overgrown walks should now be cut back or taken up and replanted. Cuttings of Laurel and other shrubs may now be prepared and put thickly into nursery-beds in the reserve garden. Anemone roots to be planted 2 inches deep. Tulip-beds to be prepared by digging the ground

12 or 15 inches deep, and mixing decomposed turf sandy loam with the soil. The Ranunculus-beds to be prepared by taking out the old soil to the depth of 1 foot, putting in about 6 inches of well-rotted cowdung at the bottom, and then some good rich loam, mixed with a little of the cow-dung, to 6 inches above the level of the surrounding surface, the bed when finished sloping from the middle to the sides.

GREENHOUSE AND CONSERVATORY.

Hints from the thermometer should regulate the admission of air to these structures. Favourable weather should be taken advantage of to the utmost extent, and in many cases openings for air may be left all night. The careless practice of opening the sashes at stated intervals to any certain degree without reference to external circumstances, must, throughout the season, be avoided. Keep the Azaleas and Camellias regularly moist at the roots, never allowing them to become too dry or too wet. Shift herbaceous Calceolarias and Cinerarias regularly. Give plenty of air to Heaths and New Holland plants, and water very carefully; the same with Orange and Lemon trees. Shift advancing Pelargoniums, and water freely at the root. Take pot Chrysanthemums into the greenhouse and conservatory; water with weak manure water occasionally. Shift Chinese Primroses, and keep them in a light airy place. If any of the beautiful tribe of Tropaeolums, particularly tricolorum or Jarratti, which have flowered early in the season, start into growth, they should not be checked, but allowed to grow slowly through the winter; but if there is no appearance of this, which is best for their future success, their roots should be kept inactive in a cool place, with the soil about them quite dry, and they must be protected from mice. The necessity of a store of the various kinds of soil for potting should invite the precaution of securing a sufficient stock for winter use under cover before the drenching rains of autumn have rendered it unfit for use.

PITS AND FRAMES.

The earliest opportunity should now be taken to remove Auriculas, Carnations, Picotees, Pinks, Pansies, and all such florists' flowers to their winter quarters. Cold dry frames, raised upon a few bricks to give a circulation of air beneath and among the plants, are the best situation for them. But very little water should be given during the winter, only sufficient to keep them from flagging. Additional air should be admitted to the frames daily by tilting up the sashes in favourable weather; the vacancies around the bottoms of the frames to be filled up, and a moderate degree of protection to be given in the most severe part of the winter. Indeed, during a great portion of the winter no coverings will be required, as the plants will bear to be frozen without injury if the lights are covered with straw or litter to exclude the sun's rays, when they will thaw gradually and slowly. The frames to be looked over occasionally to see that the plants do not suffer from drip from the lights, or from slugs, snails or canker.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

MUCH the same as in previous weeks. Weather still dry, with parching east winds. Ran the Dutch hoe through every bit of ground, to give an open surface, and cut up every incipient weed. Pulled up all the Peas and Beans done bearing. A piece of Dwarf Kidney Beans still very good. Scarlet Runners, thanks to a little sewage water, are still very fine, whilst in most cottage gardens hereabouts they have done little good this season. But for the sewage we would have been in the same position. Two years ago we obtained a very superior Scarlet Rwaner from Mr. Veitch—the pods are larger and more thick and fleshy than those of the ordinary kind. White Dutch Runners and White Scarlet Runners are hardly worth growing in comparison with the old scarlet-flowered and mottled-bean kind. Of the White you obtain fine, large, long, smooth pods, but even if gathered young they never seem to eat so crisp and juicy as the Scarlet Runners. For amount of yield of real nourishing food there is no better friend to the cottage gardener than the Scarlet Runner.

We have sometimes been in the habit of associating the

Scarlet Runner with the degree of refinement and civilisation arrived at by the working classes. We can recollect when, in Scotland, the Scarlet Runner was merely seen amongst the working people as a flower trained up by the side of a window. In cottage gardens you could scarcely meet with any vegetable but Curly Greens, Cabbage, and Potatoes. Cauliflower was considered to be aping the aristocracy. The cooling Lettuce on a hot summer day, the nutritious Dwarf Kidney Bean and Scarlet Runner, were wholly discarded; and on our last visit to Scotland, though there were improvements in cottage gardens, the homely natives might well have taken a lesson from their English neighbours, who would have secured a far greater variety, and more nutritive qualities of food, from the same sized garden. The Scotch peasantry, who, perhaps, value themselves quite enough on their hardy habits, their independence of character, and their respect to the outward moralities, might well learn something from their southern neighbours as respects the useful, the healthful, and the refined. The very variety of food at a peasant's table expands alike his desires, his mind, and his heart, and tends to raise him in the scale of civilisation. The man with so few wants that nature alone will supply them, whatever peculiar excellencies he possesses, can, as a man, be little better than a barbarian. Mind, we say nothing against the man—quite the reverse—who, well aware of the benefits and the pleasures from variety of food, voluntarily deprives himself of that gratification, in order that, by his self-denial and self-effort, he may attain a desired object. There is no occasion, however, for him to try to make the world believe that fine Grapes are as sour as Crabs, merely because his means or his purposes deny him the gratification of eating them. The Great Creator, in his goodness, presented us with wonderful variety of the useful and the beautiful, that we might thankfully and temperately enjoy them all. The man who is contented with the least tempting viands, when his means would command the more nutritive and enticing, can only secure our respect when we know the means thus saved are devoted to a noble purpose—such as helping those less prosperous than himself. We certainly shall be glad to know what progress is making in cottage-gardening in Scotland, especially as to the variety of vegetables cultivated. We clearly recollect that, in a large village, or rather town, north of the Forth, there was only one man who knew how to grow and how to treat a Lettuce. A greater attention to home comforts, even as respects the table, would do nothing to undermine the taste for intellectual studies; but it might help to give us less of the rough and the uncouth in association with the advancement of intellect.

Pricked out more Lettuce, watered Cauliflower and young Cabbages, took up Carrots and Beet, and hunted for slugs, grubs, and caterpillars. Examined Potatoes. All in the ground should now be taken up, and those wanted for the new year should now be planted, with glass ready to put over them. Planted a piece of a pit with Dwarf Kidney Beans, where we can give a little heat; and cut the young fruit from young plants of Cucumbers, which we wish to produce a few in the beginning of winter, as of late we have given up growing them all the winter through. We would here state, however, in answer to a correspondent, that what was said lately of winter Cucumbers was just the result of our own practice. Had we nice plants coming on now, that we wished to bear plentifully about Christmas, and the new year and onwards, we would scarcely allow a fruit to swell before the middle of December.

FRUIT GARDEN.

Were we disposed to do anything in the way of transplanting, lifting, and planting, or even root-pruning, the dryness would deter us. In opening a ditch 30 inches deep for a fence in a meadow, the ground at that depth seemed quite dry and flaky. No pressure afforded any signs of moisture, and the lowest of it, when squeezed hard by the hand, could not be firmed together. Planting in such soil, without abundance of water, is out of the question; but preparations may be made, and in places where there is no such dryness, transplanting, root-pruning, &c., may now be proceeded with, as soon as the fruit is gathered. In planting young trees, and when they are to be moved only short distances, they will go on all the better, and make fresh

roots the sooner, if the operation is performed before the leaves lose their greenness, if there is the chance to syringe these leaves in a hot day, or to shade them from the hot sun. Where neither syringing nor shading can be given, the planting had better be delayed till the end of the month, as then moistening the foliage will be less required.

When the dryness prevents lifting and transplanting, much may be done in pruning and thinning the tops, both of trees to be transplanted, and of those that are established and intended to remain as they are. It is much more pleasant to do this now than in winter, and it will, by the admission of light and air, tell more upon the fruitfulness of the tree next season.

We have gathered all our Filberts, most of our Apples, a number of Pears, and all Plums except a few of Coe's Golden Drop, which ripened rather sooner than usual, as the tree was rather severely root-pruned last season. One advantage of this Plum is its hanging so long after it is ripe, and becoming all the richer if a little shrivelled at the stalk. Were we to state what we have been doing with other fruit we would merely be repeating what was said last week.

CHARRED-RUBBISH HEAP.

Took the advantage of the absence from home of the proprietor, and thus having smoke without annoyance, to have a large heap of prunings, roots, weeds, &c., placed together, and will cover with earth, so as partly to char, and then burn the remainder to ashes. To this heap are brought all the bad weeds, as couch grass, &c., as nothing settles them so well as burning them. We tread the heap of prunings as well as we can, and then, as leaf mould would be too valuable for a covering, we place a layer of litter and vegetable leaves all over before covering with earth and clay, which prevents the latter from falling into the middle of the heap. To make the heap more compact we frequently throw into it and over it, before the earth-covering, great lots of sawdust and refuse from the wood-yard, which thus become charred. Light where you will the heat will always reach the top, and for charring, the concealed fire must be brought down by degrees by boring holes until the base is reached. With a little care a great amount of charred matter may thus be obtained from a lot of rubbishy materials. But in such a heap if you wait until all is charred the charred matter will become less and less from the admission of air by chinks and crannies. It is best, therefore, to open such a heap when the bulk is charred, and then make a fire of the remainder, which will burn ever so much rough earth, clay, &c. A good portion of our heap will be small laurel prunings, and these when charred with other things are good for common purposes, but not so good for tender cuttings and plants in-doors if not previously well exposed to the air. Oak, Lime, and any common wood, except that of the resinous tribe are good for particular purposes, and a char heap of such wood must be carefully attended to that none of the heap may be burned into ashes.

FERMENTING-HEAP.

We have little grass to assist us this season, but all we could collect from the mowing and machining of the lawn, and the tree leaves that are falling a little prematurely, along with all the litter we could command, have been thrown into a heap to ferment, and will be found valuable in forwarding a few cuttings rather late in frames, and in helping various crops. Many things, even Lettuces, would do better in winter, and stand more air even in cold weather, if they had a foot or 18 inches of such a mixture beneath the earth in which the roots were placed. The only difficulty was procuring water to moisten the litter. In common seasons the grass would have done that admirably.

EARTH AND TURF-HEAPS.

Took the opportunity of a small meadow being planted to procure a lot of turf and earth, and will stack up the former in the manner previously indicated. It is so dry that it is hard work to take it up; but then it will come home light, and we must not miss the chance. Most probably we will let it lay roughly, and only build it in stacks when it is a little wet. In common seasons it is easy to moisten as we use it, and it will keep all the better and be more sweet from being piled up when rather dry. The gardener who never can obtain a bit of fresh turf soil is much to be pitied, and scheme how he will his employers will ultimately suffer.

Some of our best gardeners think nothing of getting soil from a distance of many miles if it suits them, and the result will generally be seen in superior cultivation.

ORNAMENTAL DEPARTMENT.

Very much the same as last week. Proceeded with repotting Pelargoniums, potting Primroses, Cinerarias, &c. The flower garden is still so fine, that we gave over taking things up, and will trust even Cloth of Gold a little longer. With north and east winds the nights have become warmer as the days are duller. Masses of Stella are still masses of gorgeousness. We will commence with Calceolaria cuttings next week.—R. F.

COVENT GARDEN MARKET.—OCTOBER 15.

Hothouse Grapes are very plentiful and of excellent quality, while of Pines there is a fair supply. Peaches are now scarce, but sufficient for the small demand which exists for them. Of Apples and Pears large quantities of excellent fruit are to be had; and in Plums a few Purple Gages are still to be met with. New Oranges are beginning to come in, the first cargo having arrived; and new Walnuts are seen in abundance. The vegetable market remains unchanged, and Potatoes are still heavy, the samples, it must be added, are remarkably healthy, the disease apparently dying out.

TRADE CATALOGUES RECEIVED.

S. Ponsford & Son, Loughborough Park Nurseries, Cold Harbour Lane, Brixton, Surrey.—Catalogue of General Nursery Stock; Select Catalogue of Dutch and Cape Flower Roots.

André Leroy, Angers, France.—Supplément au Catalogue de 1863; Tableau des Arbres Forestiers et d'Ornement déjà fortis.

James Veitch, Royal Exotic Nursery, King's Road, Chelsea, and Coombe Wood, Kingston Hill, Surrey.—Catalogue of Hardy Trees, Shrubs, Coniferae, American Plants, &c. 1864-5.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

CATERPILLARS ON CABBAGEWORTHS (*T. Record*).—As far as we can discern from your brief description they are the offspring of two or more of the white cabbage butterflies (*Pontia brassicae* and *P. napa*); and of the cabbage moth (*Mamestra brassicae*). Why they at one time preferred your neighbour's crops, and now have selected yours, defies our penetration. You have no remedy but hand-picking.

MOVING VINES FROM OPEN GROUND TO GREENHOUSE (*Old Subscriber*).—The best time to plant Vines is early in March, and you may move those intended for outside and inside planting at that time. One Vine to a rafter is quite sufficient when these are 3 feet apart, which is the proper distance, and quite close enough when plants are grown under them, so that you will have only room for nine Vines; but you do not say how you propose training them. Unless the Vines are better than out-door Vines usually are, we think they will do you little service for some time. Young Vines are preferable to old ones from any quarter, especially from out of doors, for the bad training has to be surmounted, and they do not usually push freely.

DENDROBIUMS PAXTONIANUM AND NOBILE AFTER BLOOMING (*James Hurst*).—They should not be cut down after blooming, as from their bases rise the future stems, and thus a kind of support is afforded to the young growths. Any that are old and dead may be removed.

POTTING ROSE CUTTINGS (*Idem*).—The best time to pot Rose cuttings inserted in September is April, affording them during the winter the protection of a frame and lights, or hand-glasses. Admit air in mild weather, especially when humid, and gradually harden them off by tilting the light or lights. By the middle or end of April they will be ready for potting, after which continue them in the frame for a time, keeping close for a week or ten days, and then admit air, gradually hardening-off by the end of May. They may then be planted out, or plunged in coal ashes, in an open yet sheltered situation, and reported in September.

BEST PURPLE VERBENA—**NASTURTIUM PROPAGATION** (*E. G. H.*).—There is no better purple Verbena as a bedder than Purple King. Verbena venosa is a frame perennial, harder than many of the varieties from Melin-dres; but even it requires the protection of a frame, a dry spot, light soil, and the protection of mats, in addition to the lights in severe weather. In certain genial and sheltered situations it stands our climate. Nasturtiums generally may be raised from seed, but if of the better kinds of Tropaeolums, cuttings are preferable. You fail to ask specifically as regards the culture of Tropaeolum speciosum, and we cannot furnish answers when we do not know what is asked.

MYSPIPHYLLUM ASPARAGOIDES CULTURE (*M. D.*).—Pot in a compost of turfy loam, fibry sandy peat, and leaf mould, in equal parts, with a free admixture of sand. Drain the pot to one-third its depth, and do not overpot the plant, employing a size that will cramp the roots rather than allow room to spare. Grow in a greenhouse, and train as near the glass as possible; at all events select a light airy situation. When the plant commences growing water copiously, increasing from the commencement until the maximum is reached when the foliage is growing rapidly. After this give no more than is sufficient to keep the foliage fresh, and when this begins to turn yellow do not supply a drop for the next three months, and expose the foliage to all the light and sun heat possible. This will ripen the wood so well, and the eyes will be so well matured, that it will not fail to bloom with a continuity of such treatment, which is similar to the conditions which it enjoys in its native habitat—the Cape of Good Hope. It ought not to die down or be dried off until early autumn, but it may be treated so as to bloom at different periods of the year by varying the time of growth and rest.

HOTWATER APPARATUS FOR GREENHOUSE (*Jane*).—We have no experience of the stove you name, and we fear the lamps, unless there were a pipe to convey the vapour into the open air, would injure the plants. If you propose to employ gas try Clarke's new gas hotwater apparatus, which is highly spoken of by many who have tried it. If you have not gas at command try a small saddle boiler set at one end, the boiler inside but the furnace-door outside of the house, and connect with it four-inch flow and return pipes, and run them along about 1 foot from the front wall of the lean-to. This will afford sufficient heating power to prevent frost injuring any description of greenhouse plant, and you may have them in growth all the winter, as you wish. The next best plan is to have a furnace at one end and a flue along the front, which will be quite sufficient to keep out frost with a moderate fire.

REMOVING PINE SUCKERS (*St. Omer*).—We would remove the suckers now, and have them rooted plants before severe weather sets in. As they only serve to impoverish the parent, they might as well be removed at once. It is the practice of good Pine-growers to twist out the suckers that appear before the fruit shows with a pair of long-handled pincers, when the suckers can be fairly laid hold of, as when they are removed early the stem of the plant is not so likely to be injured as when they are allowed to remain until nearly the size of a fruiting plant. When Pines are planted out, as yours are (no new thing, by-the-by, in England), and when the sorts are such as arrive early at maturity, especially those of the Queen race, one, or, at the most, two suckers rising from the neck of the plant, or at a little beneath the soil, are allowed to remain on the parent. These grow until the fruit is ripe, when the parent is cut away, and the sucker grows amazingly, and not unfrequently in eighteen months produces a fruit larger than the parent. Should the suckers rise from the axis of the leaves at some distance above the soil, they, being ineligible, are either twisted out with a pair of pincers as they present themselves, or have their hearts drilled out by thrusting a pointed square stick into them, and twisting it round several times, but not so as to injure the old plant.

BRANCHES OF EVERGREENS FOR BEDS IN WINTER (*A Constant Reader, North Devon*).—The parts most eligible for this purpose are densely-branched shoots of all evergreen trees and shrubs. There is not an evergreen that may not be employed in this way. Arrangement is a matter of taste, and that you seem to understand. As to their adaptability for the purpose specified, they are better than nothing, but after all look well for a time as the weather is wet or dry. The proper place for branches of all kinds not planted to strike root, or to serve some purpose other than that of living plants, is the rubbish-heap. To make a garden a cemetery is worse than having nothing in it, for neatness is superior to having faded autumn-tinted foliage in the beds all winter, and dead-looking plants in the spring.

ADMITTING AIR TO GRAPES (*Idem*).—In fine dry days the lights may be opened early in the morning, and remain open all day; but at night they should be closed before the heavy autumn dews begin to fall, using fire by day only. If you can have a little air on at back without wet getting in at night by all means do so, otherwise the house had better be closed. It is a warm confined moist night air that is so injurious to Grapes hanging, and air at night, especially at this season, does more harm than good. We have in the press a book on Vine culture, which we think will suit you.

BOOKS (*J. O., Bradford*).—You can have Appleby's "Orchid Manual, for the cultivation of all kinds of Orchids," for thirty-two stamps free by post from our office; and the "Fern Manual" for sixty-four stamps.

LEAN-TO HOUSE FACING THE NORTH (*T. T.*).—If you had not been at the trouble of putting in front lights, and we suppose glass also, your north house would have made an excellent one for Ferns: as it is, it will do very well for that class of plants; and there are many interesting kinds that will endure a great deal of frost, which you may grow in Scotland in a house not heated. The house will also do very well for Camellias, and many hard-wooded plants will endure a great amount of cold, but we would not advise Heaths, as they like sun and air. Azaleas, however, will most likely do well with you, and the hybrid Rhododendrons will succeed admirably, while in spring and summer your house will be just suitable for flowering plants, as Calceolarias, Geraniums, and Balsams. If you determine on wintering Camellias and the like, do not be tempted to try an Arnott's stove in severe weather; rather cover up in any rough way, if it were even by throwing straw amongst the plants, and if they are frozen let them thaw slowly and gently, and the damage amongst hardwooded plants will not be so great after all.

PEACHES AND NECTARINES ON A WEST ASPECT (*Monmouth Subscriber*).—There can be no question that Peaches and Nectarines would ripen with greater certainty under glass than without it; and as you wish to build such houses cheaply, we advise you to make the bulk of your roof a fixture, but to have some good large flaps at top as well as in front. Assuming the length of rafter to be 15 feet, we should say let 2 feet of that at top be on hinges to lift up by an easy contrivance, and the remaining 13 feet might be all a fixed roof. A small but neat bar of T-iron will support the glazing-bar from sinking if fixed from rafter to rafter in the middle. The front wall may be wooden boards almost its whole depth.

WINTERING TOM THUMB GERANIUMS IN A HAY-LOFT (*T. H.*).—You may winter them as you say, in a hay-loft, if there be light to it, but do not place them there until the weather is likely to set in frosty. If you have a cold pit with lights, and watertight, let them stand there as long as the weather is open and mild, say perhaps till the first week in December, covering the frame at night when frosty, but giving air at all times when mild, keeping the plants dry, and checking growth by exposing them gradually to cold winds, so as to have them at rest, or nearly so, before setting them into the hay-loft. Cover up while there, if it be required, keeping them dry almost to withering, and remove them in March to some place where there is more light. If they are in pots let them remain so, and if potbound so much the better.

FRUITING VINES IN POTS (*Idem*).—If the wood appears ripe, and the leaves easily part from the shoots, they may be pruned at once. A small shoot or two at the top is of no particular consequence. It would, however, be better to let them remain outside after pruning for a little time, say a month or so, to harden, when they may be introduced into heat gradually. It would be better not to fresh pot them now, but place them in saucers or pans, and when fairly started feed them with liquid manure at times. Enlarging the pot at the present time will only cause the production of more wood, the fruit deriving but little benefit from it. Do not be in too great a hurry in forcing. We have seen many pots of Vines spoiled by being forced too early, the incipient bunch going blind, and producing no berries worth caring for.

APPLE AND PEAT TREES FOR ESPALIERS—PYRAMID PEARS (*Yorkshire*).—We think the espaliers would be profitable, and that the border of flowers in front next the walk will look well; but the flowers should be of low growth, and not planted nearer the trees than 2 feet, therefore your border should be at least 1 foot wider, or the trees planted that distance further from the walk. At the commencement the flowering plants may, of course, be planted wider in the spaces not covered by the trees; but for the fruit trees to do any good they must not be crowded by plants, but have free exposure to light and air. You may have the espaliers any height, but we prefer them 6 feet. Galvanised wire, if properly made, is preferable to ordinary wire, though the latter will answer well if kept painted. The wire may be stapled to wooden posts, which should be fixed firmly in the ground, and charred to the depth they are in the soil, and a few inches above it. Above the surface they should be well painted, or coated with boiling gas tar. The posts should be 2 feet in the ground, and the end ones double the strength of the inside ones. The first wire should be 1 foot from the ground, and the others 9 inches or a foot above it, which will make seven wires necessary. If you train the trees horizontally, the posts should be 20 feet apart for Pears on the pear stock, and 12 feet apart if on the quince. The posts for the Apples should be 20 feet apart for those on the crab stock, and 15 feet apart if on the paradise stock; and the trees of both Apples and Pears should be planted halfway between them. The two end posts may be made firm by driving a post 3 feet from them in a line with them outwards, and fastening a wire to them, and then to the first upright post 5 feet from the ground. The other posts are best secured by ramming the soil round them firmly. We would have the Apples on the paradise, and the Pears on the quince stock. Eleven Apple trees would therefore be required—say eight for baking and three for dessert—as you have a greater quantity of Pears. They may be—dessert Apples: Red Astrachan, Blenheim Orange, Golden Pippin, or Court of Wick. Kitchen Apples: Keswick Codlin, Nonsuch, Manx Codlin, Lord Suffield, Graveston, Waltham Abbey Seedling, or Golden Noble, Winter Pearmain, and Dumelow's Seedling. We would have the Pears on the quince stock at 12 feet apart, as stated. Thirteen trees would, therefore, be required. They may be the following, which come into season in the order in which they are named: Doyenné d'Eté, Jargonelle, Colmar d'Eté, Williams's Bon Chrétien, Louise Bonne of Jersey, Marie Louise, Thompson's Forelle or Trout Pear, Hacon's Incomparable, Beurré Diel, Alexandre Lambré, Beurré d'Aremberg, and Beurré de Rance. We presume that by dwarf standard Pear trees you mean bushes and pyramids, which are the most suitable for planting along the sides of paths in kitchen gardens. Standard trees shade other crops too much. We think your arrangement of the garden very good, and hope these hints may be useful; but if you want further advice do not hesitate about asking us for it. We never deviate from our rule of not recommending dealers.

VINE ROOTS INSIDE GREENHOUSE (*J. J.*).—If the roots be only covered with bricks to the width of the path, leaving a considerable surface bare, we do not think any great harm will result to the roots; but if you cover the whole of the surface inside they cannot be fed or watered, and will, besides, be shut out from air. It is usual in such cases to have a pathway formed of laths, which are moveable, thus facilitating the attention necessary to be bestowed on the border, which consists in watering when the Vines are active, so as to keep the soil in a healthily moist state, and giving a mulching of 3 inches of short manure every spring, to be covered with an inch of loam to take away its untidy appearance.

PLANTING AN ORCHARD OF THREE ACRES (A Subscriber).—In giving advice of this kind somewhat more of your ulterior objects ought to be known than is given in your otherwise well-penned letter. We confess we are no particular admirers of closely-trimmed fruit trees anywhere excepting against a wall, espalier, or similar place. If we were, like you, near a fashionable watering-place, where there is a good sale for fruits in summer and early in autumn, we would trench the ground as you propose, plant standard Apples about 20 feet apart each way, and fill the ground between with Gooseberries or Currants at 5 feet apart, cutting away and removing these bushes as the Apple trees advanced, and eventually sowing the orchard with grass. If the situation is very windy, dwarf trees trained up fashion might be substituted, and these may do much closer, say 2 feet apart. We would not, however, recommend miniature trees if a large quantity of fruit is wanted. We have seen several Apple trees the present season yielding forty bushels of fruit each, and it would take a great number of small bush trees to accomplish this, besides the trouble and expense of training the latter. As you confine your list to ten varieties, and believing you would do better by growing chiefly early sorts, we would recommend the following, the greater portion to be of the first-named, which are early: Devonshire Quarrenden, Kerr Pippin, King of the Pippins, Celingi, Blenheim Orange, New Haworthden, Mapson's Seedling, and Lord Sunfield, all summer and autumn fruits; and for late keeping try Golden Knob, Wellington, Winter Queening, or Court-Pendu-plat. For appearance in early summer, the Red Juncating, Red Astrachan, and Cox's Orange Pippin, are all good; while for early bearing, and the property of filling the basket quickly, the Keswick Codlin has few equals.—J. R.

GLOXINIAS GROWING IN A VINEY (Ruby).—Pot them in February, keeping them until then in any kind of light soil in a dry part of the viney, from which frost is excluded, and employing a compost of turfy loam and leaf mould in equal parts, with a free admixture of silver sand. Provide drainage to one-fourth of the depth, using pots two-thirds larger than the bulbs. Water sparingly until the growths appear, then give more gradually as growth progresses. If you have a hotbed you may plunge the pots in it, and grow these plants there for six or eight weeks, and thence remove to the viney, and place on a shelf near the glass. Thunbergia coccinea to do any good requires a stove temperature, though it will do moderately in a temperature of not less than 45° in winter. Boussingaultia baselloides should do in a viney, which is quite warm enough a place for it. It requires a compost of peat and loam in equal parts, with a free admixture of silver sand, abundant water when growing, but none when at rest, and all the light possible after the foliage has attained its full size, a free circulation of air being also afforded. You may keep the Caladiums named in a heated glass case, only they must not be too wet in winter; maintain a temperature of 55° to 60°. They luxuriate in a compost of turfy loam and leaf mould in equal parts, with a free admixture of sand.

VINES FROM EYES VERSUS LAYERS—PLANTING OLD SMALL VINES (M. F.).—Vines from eyes are preferable to those from layers, because the joints of the wood are shorter, and they have the advantage of going on progressively to perfection without any drawback: whereas layers are liable to receive a check when detached from the parent, which prevents their growing freely for some time afterwards. It would not be judicious to plant in a permanent border Vines that have been in small pots for three or four years, and have thin old-looking canes, for they seldom take to the fresh soil well, and make correspondingly poor growths. Free, young, strong, healthy-growing canes, the thickness of the little finger, which were in the eye this spring, would make double the growth if planted next spring, and give a crop of Grapes the year following: whereas the others will be only recovering themselves preparatory for a start another year. For planting in permanent borders we prefer young moderately strong well-ripened canes to those that have been grown years in pots, even though strong.

DOUBLE SENECCIOS (W. Dillistone).—Your double Senecios are very good; the one named Magenta very attractive in colour. Its dwarf habit is a great recommendation. The other varieties are too dark for bedding purposes. In our opinion Senecios are better adapted for pot culture as decorative plants. The variety Magenta is most desirable from its brilliancy of colour. Not having seen the plants growing, we can only speak of the propriety of names as applied to colour.

CUCUMBER-HOUSE—COLD VINEY (J. H. C.).—Your proposed arrangement will do for Cucumbers after the end of February. For winter supply you would require at least three pipes below the central bed, and three pipes on the coldest side of the house. A good arrangement for such a house would be a bed in the centre 4 feet wide, a walk on each side 2½ feet wide, and a shelf next the sides all round a foot wide. Did the house stand north and south, especially—but even as it does stand—we would prefer having a bed on each side, which, with middle walls, would take up 3½ or 4 feet, and thus leave a path down the middle of from 3 to 4 feet. Two four-inch pipes beneath each bed would then do, and two round the house for top heat. For winter work a third would be desirable for the coldest side, as the health of Cucumbers depends much on not overheating the heating medium. For a cold house we would have one Buckland Sweetwater, one Royal Muscadine, one Muscat Hamburgh, and the rest Black Hamburghs. For a house to be heated take the first three, two Hamburghs, one Muscat, and one Lady Downes'.

SEEDLING FUCHSIAS (John Scott).—Your specimens of Fuchsias arrived in a very sad condition. The names not being fastened to each specimen renders it difficult to recognise them. To do your seedlings justice we should see plants in flower. Presuming that the one with the pale mottled rosy purple corolla is Loveliness, we should say that was the best, although the sepals are rough. That with the large double white corolla, if free in flowering, would make a good decorative plant; the other specimens have no novelty about them. Much depends on the habit of the Fuchsia to render it useful. The Petunia is no advance upon many well-known named varieties.

NAMES OF FRUIT (S. S.).—2, Court-Pendu-plat; 3 and 4, Court of Wick; 5, Golden Pippin; 6, Robinson's Pippin; 10, Norfolk Beaufin. Others not recognised. (A. H.)—6, Barcelona Pearmain; 7, Vicar of Winkfield; 8, Round Winter Nonpareil; 10, Scarlet Nonpareil; 11, Green Nonpareil; 13, Triomphe de Jodoigne. Others not recognised. (Ten-years Subscriber).—1, Forge; 2, Christie's Pippin; 3, Cellini; 4, Gravenstein; 6, Striped Beaufin; 8, Golden Harvey; 9, Same as No. 10; 10, Same as No. 9; 12, Adams's Pearmain; Baking Pear, Black Worcester; 14, Same as No. 2; 15, Carel's Seedling. Others not recognised. (East Retford).—2, Golden Winter Pearmain; 4, Golden Noble; 7, Catillac; 9, Court of Wick; 10, Api Petit. Others not recognised. (J. W., Southgate).—Apples.—1, Gloria Mundi; 2, Blenheim Pippin; 3, Dutch Mignonette; 4, Scarlet Nonpareil;

5, Eibston Pippin; 6, Court-Pendu-plat. Pears.—1, Napoleon; 2, Marie Louise; 3, Beurré de Rance; 4, Easter Beurré; 5, Beurré Diel; 6, Beurré d'Aremberg; 7, Fondante d'Autunome. Others not recognised. (N. F. H. H.)—1, Marie Louise; 2, Beurré Diel; 3, Passe Colmar; 4, St. Germain; 5, Catillac; 6, Williams's Bon Chrétien. (H. P.).—Your Apple is Coe's Golden Drop.

NAMES OF PLANTS (Lex).—*Cyanosis vitata*. (*Leaflet*).—It is quite impossible to name your plants from pieces of leaves only: we must see the flowers. (*Constant Reader*).—*Juniperus communis*. (*J. M. K.*).—The plant with a prickly pointed leaf is *Ruscus aculeatus*. The other two are not in a nameable state. (*Mary*).—*Mesembryanthemum cordifolium*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY-CLUB MEETING.

(From a Correspondent.)

THE half-yearly meeting of the Poultry Club was held in the board-room at the Agricultural Hall, Islington, on the 1st inst., when about twenty members were present. Upon the motion of Mr. Beldon, Mr. Kelleway took the chair. The following new members were then elected:—Messrs. J. E. Powers, H. Lacy, W. J. Pope, J. Fletcher, J. Crook, jun., W. Guerrier, J. Smith, J. Anderson, A. Crook, C. Priest, H. Bates, — Colley, F. W. Else, M. Headley, J. Monsey, and W. B. Tegetmeier.

Mr. Zurhorst gave notice of motion, respecting the absence of the minute-books, &c., of the Club, for the next meeting.

Mr. Beldon said, that with respect to the book of rules for judging, he considered that the dissatisfaction shown at the principle out of doors was due to a misapprehension of their purpose. The rules laid down were really a standard of excellence for the guidance of exhibitors. It was absurd to think that the Judges were to make their awards book in hand; but any flagrant violation of the acknowledged standard of excellence by a Judge would entail an explanation from him by the Stewards. Mr. Beldon, to remove the only possible point of opposition to the Club, moved that the name be altered to "A Standard for the Guidance of Poultry Exhibitors." This being seconded, was unanimously adopted. It was stated that the revised edition would be ready in a few days, and each member immediately supplied with a copy.

A long discussion took place about a monthly periodical on poultry matters; but from the experience of some members present it was not deemed advisable, it being certain to entail a pecuniary loss.

The appointment of the Judges at Birmingham was next brought forward, and it was resolved to memorialise the Committee that if they still appointed some of their old Judges they would select fresh ones to act with them in whom exhibitors had confidence.

The next meeting was fixed for the Monday of the Birmingham Show at the Bingley Hall Tavern at three o'clock. The meeting then dispersed after passing votes of thanks to Mr. Kelleway, the chairman, and Mr. Ashton, who acted as secretary.

TUNBRIDGE WELLS POULTRY SHOW.

We are always glad to note progress of poultry in connection with agriculture. It is a natural thing, and the association is therefore a correct one. The good people of Kent are not slow in learning. Last year was the first exhibition of the sort they have had, and they have soon applied the lesson which they then had placed before them. From its soil, its contiguity to London, and from tradition, Kent should be, as it was formerly, one of the chief poultry providers of the London market. Many villages and places retain in name an old reputation. We recollect when Westerham was famous for its breed, just as Le Mans and La Flèche are for theirs in France; and Handcross, Cuckfield, and Dorking are here.

There was a great increase in Dorkings, Geese, Ducks, and Turkeys—all among the most useful and marketable of the dwellers in the yard, or on the farm. The progress was not confined to the numbers, it was as perceptible in the quality. Many of the birds shown were fit for any exhibition in England, and would hold their own creditably anywhere. There were twenty-one pens of Dorkings, many of them most excellent. The Rev. Mr. Barnes showed three

pens, taking first and second, and a high commendation. The first-prize pen sold readily for ten guineas. We have seldom seen two better pens; but there was the old mistake. If the cock from the second-prize pen had been put with the first-prize pullets, it would have been an improvement. Mr. Simmons's birds were very good. Eight pens were deservedly mentioned. The *Polands* and *Spanish* do not seem to grow in public estimation. We imagine much of this may be attributed to the fact, that non-sitters are troublesome birds on a farm. They involve the necessity of keeping two breeds, and these are tiresome to keep distinct. If they are allowed to mingle, then we soon come to the abomination of all abominations—the strange creature called a "barn-door fowl," an "*olla podrida*" made up of a small contribution from Spanish, Poland, Dorking, Game, "and many others, which now to describe would be too long." The idea is suggested to us by having before our eyes while we write, a picture, by a Flemish master, said to possess considerable merit. The cock is yellow and white with blue legs, he has a lark crest, and a cup comb; one hen is white with a splashed topknot; another is black all over, she is also crested; another hen is brown and white—all have dark legs. In the country where this was painted they are still called "Boor's fowls," and invoiced as such when sent over for sale. A pure breed is more valuable, and quite as useful. The food consumed by one of these equals in expense the consumption of a pure bred and good fowl. One is worth on table, or in the market, twice as much as the other, and surely uniformity and harmony of colour and markings shall be worth something in the yard. *Hamburgs* were poorly represented in numbers; but Mr. Brassey, who took nearly all the prizes, did so with good birds, especially the Golden-pencilled. We question whether it would not be well another year to give fewer prizes for the *Hamburgs*, and more for the *Dorkings*. In the "various class," Mr. Brassey was successful with some good *Crêve Cœurs*. There seems to be a speciality at this Show for good Duckwings. All the *Game* were excellent, these especially. Mr. Gee took both prizes. Messrs. Cheney and Simmons showed good *Bantams*.

The *Turkeys* were very meritorious. Lord Abergavenny took both prizes, hand run by Sir Walter James.

Geese were excellent, especially Mr. Sharp's first-prize pen of Toulouse. Mr. Wyer also showed heavy birds.

Aylesbury Ducks were a good, but not an even class. Mr. Gee's birds which took both prizes had an easy victory, on account of the excellence of their points; but there were larger birds with yellow bills, and one pen of very good Ducks slightly foul-feathered. *Rouens* were another good class, and brought deserved honours to Messrs. Sharpe and Field. Another, and in our opinion, a very useful class at an agricultural show, was one for "any other Ducks." Some very large birds were shown. Mrs. Cramer Roberts took first, and Lord Abergavenny second.

The Show is held in a lovely spot, and was favoured with beautiful weather. Like most agricultural shows, it is a holiday, and a source of enjoyment to all. The Committee is a painstaking and active one, deserving the success they meet, and Mr. Richardson is an urbane and excellent Secretary.

Mr. Baily, Mount Street, Grosvenor Square, was the Judge.

LONG SUTTON POULTRY SHOW.

THE first annual Show of Poultry and Pigeons was held on the 12th inst., and was in every respect a great success, many of the birds being of great merit. Amongst the number may be mentioned the *Spanish*, shown by Mr. W. Massey, Gedney; Silver-pencilled *Hamburgs*, by Mr. T. J. Saltmarsh, Chelmsford; and *Brahma Pootras* by Mr. E. Sherman, Chelmsford. A fine pen of *Silver Polands* were well shown by Mr. G. Boothby, of Louth; and an exquisite pen of *Game Bantams* by Mr. G. Clarke, of Long Sutton.

A good collection of *Pigeons* were shown, the prize pens being of extraordinary merit.

The entries numbered 136 pens. Upwards of £18 was taken at the door, though the admittance was only 6d. each until four o'clock in the afternoon, when the Show was opened free.

It is the intention of the Committee to publish a much more extended prize list another year, as they now have the patronage of the members for the county and the gentry of the neighbourhood. We wish it success.

DORKINGS (Any colour).—First, J. A. Clarke, Long Sutton. Second, J. Vorley, Holbeach. Highly Commended, G. Boothby, Louth; Mrs. J. Clarke, Long Sutton.

GAME (Any colour).—First, Miss Kemp, Fleet. Second, H. Snushall, Gedney.

SPANISH.—First and Second, W. Massey, Gedney.

COCHIN-CHINA (Any colour).—First, Mrs. W. Massey, Gedney. Second, E. Gregory, Leverington. Highly Commended, I. Whitsed, Holbeach. Commended, P. Hutchinson, Spalding.

HAMBURG (Any colour).—First, T. J. Saltmarsh, Chelmsford. Second, W. Stevenson, Gedney Marsh. Highly Commended, T. J. Saltmarsh. Commended, G. Lee, Gedney.

ANY VARIETY NOT NAMED ABOVE.—First, E. Sherman, Chelmsford. Second, G. Boothby, Louth.

GAME BANTAMS (Any colour).—First, G. Clarke, Long Sutton. Second, R. Swift, Southwell. Commended, J. Barnes, Peterborough.

ANY FARMYARD CROSS.—Prize, G. Clarke, Long Sutton.

MARKEET CHICKENS of 1864.—First, J. A. Clarke, Long Sutton. Second and Third, J. Vorley, Holbeach. Commended, W. Oliver, Long Sutton. M. J. Clarke, Long Sutton.

DUCKS (Any variety).—First, J. Eno, Long Sutton. Second, J. G. Hobson. Highly Commended, W. Wright, Sutton.

TURKEYS (Any colour).—First, Mrs. Harris, Sutton. Second, W. Wright.

Highly Commended, T. Snushall, Gedney.

GEES (Any colour).—Prize, B. Day, Sutton.

SINGLE COCK (Any Breed or Cross).—First, E. Sherman, Chelmsford. Second, J. Vorley, Holbeach. Third, G. Manning, Springfield.

FANCY PIGEONS.—First, Mrs. W. Massey, Gedney. Second, W. Massey, Third, D. Woodhouse, Nottingham. Highly Commended, I. Whitsed, Holbeach; P. Hutchinson, Spalding.

BEST RABBIT.—First, Master F. Medd, Long Sutton. Second, Miss Bennett, Long Sutton. Third, W. Beaty, Long Sutton. Highly Commended, G. Manning, Springfield.

BEST THREE RABBITS.—Prize, D. Osborne, Long Sutton.

Mr. James Monsey, of Norwich, officiated as Judge.

WORCESTERSHIRE POULTRY EXHIBITION.

THE Committee of the Worcester Poultry Show have just held their ninth annual meeting in the Corn Exchange of that city. A more excellently adapted building for every purpose of a moderate-sized show it is difficult to imagine, as it is not only well lighted, but ventilated in a manner so perfect as to leave nothing to be desired. Thanks to the persevering and very strenuous exertions of Mr. John Holland, from whom many more assuming exhibitions might with profit take copy, everything passed off quite pleasantly and in order, each duty being fulfilled in the time originally appointed, thus creating none of those unexpected delays, and consequent after-bustle and hurry to make up lost time, to which cause alone not a few of our poultry meetings may entirely attribute their eventual failure. It is an equally gratifying result to find that not only did the entries of poultry on this occasion outnumber by more than twenty pens even the largest of the eight preceding Worcester Shows, but it is equally important to note down, that the quality of the birds exhibited was a decided improvement over those hitherto competing.

With these few well-deserved remarks, we will now proceed to make a few observations on the classes generally. *Game* fowls headed the lists, and here from evident inattention to the rules of the prize schedules, two most excellent pens were disqualified for exhibiting one pullet and cockerel in the stead of a pair of pullets and cockerel. Too much careful attention cannot be devoted by intended exhibitors to the rigid examination of each particular prize list, as it by no means follows that the rules of one society should tally precisely with those of similar meetings in the neighbourhood. Vexation and annoyance must ensue, although the blame rests beyond question at the doors of those parties only who have by mischance made a false entry, for the rules and regulations must always be strictly enforced without favour or affection to any one. In the *Game* classes a great and somewhat general drawback arose from the cockerels having been so recently "dubbed" as to be still suffering depression from this operation. It is an unwise step to subject them to the increased suffering of a poultry show until perfectly recovered. There were several cockerels, however, exhibited, that in a few weeks to come will show in greatly improved condition. The *Spanish* class was a remarkably good one, but it was obvious to any one at all conversant with poultry culture that several of the so-called pullets exhibited were birds indisputably of far greater age than represented. It is not

frequently that so good a class is met with at any local show as were the Grey Dorkings at Worcester; and we noticed, also, some especially good White Dorkings in another part of the Exhibition. One of the triumphs of the Worcester Show, however, centred in the classes for *Cochins*, all three of these classes were far beyond general expectation, and the competition was necessarily most severe. This remark will apply with equal force to both the Buff, Partridge-coloured, and the White Cochins. Some unusually good *Brahmas* were exhibited in their class, and some very fair specimens were also shown of this variety in the "selling class." In *Hamburgs* the Golden and the Silver-spangled breeds were shown in numbers and quality that left little to be desired; the Silver-pencilled ones, for which this neighbourhood has been for so many years celebrated, were an exceedingly good class, and the Silver-spangled *Polands* and the Black *Polands* were equally praiseworthy. In the Any variety class were shown first-rate Silky fowls, Malays, Andalusians, Black *Hamburgs*, and White Dorkings. The Sebright *Bantams* were decidedly superior to those that have been of late years exhibited, and the White and Black *Bantams* were also good.

In *Geese* and *Ducks* Mrs. Seemons was as usual quite at home in the prize list, and left very little for division among the remaining competitors. Sir St. George Gore, however, sent a pen of exceedingly good-plumaged Carolina Ducks. Thos. Harvey Dutton Bayley, Esq., exhibited his unapproachable pen of Grey Call Ducks; whilst the display of Buenos Ayrean Ducks was a show in itself, and this class consequently was one of the most interesting portions of the whole exhibition. The "selling class" consisted of over forty pens, many of which at once changed hands from the very limited price enforced upon them by the conditions of the prize schedules; in fact, it drew forth quite a competition among intending purchasers, and proved beyond question one of the most remunerative classes to the Committee that appeared on their list of premiums.

No *Pigeons* were exhibited at Worcester, and the withdrawal of encouragement this year from so popular a portion of such meetings might possibly well deserve reconsideration on future occasions.

The weather very luckily turned out most favourable, and a band of the Volunteers, placed on a stage outside the entrance, proved very attractive.

GAME (Black or Brown-breasted Reds).—First, Sir St. G. Gore, Bart. Hopton Hall, Wirksworth, Derbyshire. Second, J. Cock, Worcester. Highly Commended, W. K. Duxbury, Leeds.

GAME (Duckwings and other Greys and Blues).—First, E. Aykroyd, Bradford. Second, Sir St. G. Gore, Bart., Wirksworth. Highly Commended, A. B. Dyas, Madeley, Salop.

GAME (Any other variety).—First, J. Cock, Worcester. Second, E. Winwood, Upton-on-Severn.

GAME COCKERELS (Any variety).—First, Sir St. G. Gore, Bart., Wirksworth. Second, T. Statter, Whitefield, Manchester. Highly Commended, Mrs. Hay, Sudbury, Derby. Commanded, J. Holme, Knowsley, near Prescott; A. B. Dyas, Madeley, Salop; T. Dyson, Halifax.

SPANISH.—First, E. P. Holden, Walsall. Second, G. Lamb, Compton. Highly Commended, E. Brown; W. Rose, Bristol. Commanded, W. Bradley, Worcester; A. Heath, Calne, Wilts; W. K. Duxbury, Leeds.

DORKINGS (Coloured).—First, J. White, Northallerton. Second, Sir St. G. Gore, Bart., Wirksworth, Derbyshire. Highly Commended, Rev. J. F. Newton, Kirby-in-Cleveland; Mrs. Pettat, Basingstoke; Mrs. Young, Stratford-on-Avon; J. Hill, Burton-on-Trent. Commanded, Rev. M. Amphlett, Evesham; E. Tudman, Ash Grove, Whitchurch, Salop.

COCHIN-CHINA (Cinnamon and Buff).—First, H. Bates, Birmingham. Second, G. Fell, Warrington. Highly Commended, Rev. W. C. H. D'Aeth, Arborfield, Reading; H. Bates.

COCHIN-CHINA (Partridge and Grouse).—First, T. Stretch, Ormskirk. Second, E. Tudman, Whitchurch, Salop. Highly Commended, P. Cartwright, Oswestry. Commanded, C. H. Wakefield, Malvern Wells.

COCHIN-CHINA (Any other variety).—First, R. Chase, Balsall Heath, Birmingham. Second, W. Dawson, Hopton Mirfield. Highly Commended, F. W. Zurhorst, Donnybrook, Dublin; G. Lamb, Compton. Commanded, Mrs. St. John, Basingstoke.

BRACHMA POOTRA.—First, P. Statter, Manchester. Second, J. K. Fowler, Aylesbury. Highly Commended, Mrs. Seemons, Hartwell, Aylesbury. Commanded, J. Pares, Chertsey.

HAMBURGS (Gold-pencilled).—First, J. Robinson, Vale House, Garstang. Second, Rev. R. Roy, Worcester. Highly Commended, J. Fielding, Newchurch; F. Pittis, Newport, Isle of Wight.

HAMBURGS (Silver-pencilled).—First, Sir St. G. Gore, Bart., Wirksworth. Second, J. Robinson, Garstang. Highly Commended, Rev. R. Roy, Worcester; T. W. Walsh, Worcester. Commanded, P. Foxwell, Worcester; D. Illingworth, Burley, near Otley.

HAMBURGS (Gold-spangled).—First, B. Boynes, Keighley. Second, J. Leech, Newcastle. Highly Commended, Sir St. G. Gore, Bart., Wirksworth; G. Brook, Huddersfield. Commanded, T. May, Wolverhampton.

HAMBURGS (Silver-spangled).—First, E. Collinge, Clough Middleton. Second, Sir St. G. Gore, Bart. Highly Commended, T. Davies, Newport, Monmouth; J. Fielding, Newchurch; G. Whitcombe, Twigworth Villa, near Gloucester.

POLANDS (Gold or Silver).—First and Second, G. C. Adkins, Lightwoods, near Birmingham. Highly Commended, Mrs. Blay, Worcester.

POLANDS (Black, with White Crests).—First, J. Smith, Keighley. Second, H. Carter, Upperthong.

ANY DISTINCT VARIETY NOT INCLUDED IN THE ABOVE CLASSES.—First, Rev. P. W. Storey, Daventry (Silky Fowls). Second, J. Robinson, Garstang (White Dorkings). Highly Commended, Rev. G. F. Hodson, North Petherton (White Dorkings); Mrs. Blay, Worcester (Andalusians); W. K. Duxbury, Leeds (Black *Hamburgs*); J. Hinton, Hinton, near Bath (Mala).

GAME BANTAMS (Any variety).—First, C. W. Brierley, Middleton. Second, J. H. Turner, Sheffield. Highly Commended, Sir St. G. Gore, Bart., Wirksworth; J. Croxton, Jun., Wakefield; J. Munn, Shawclough.

BANTAMS (Gold or Silver-laced).—First and Highly Commended, M. Leno, jun., Dunstable, Beds (Silver-laced). Second, Rev. G. F. Hodson, North Petherton (Gold-laced). Highly Commended, Mrs. Pettat, Basingstoke, Hampshire; R. Adams, Birmingham. Commanded, T. C. Harrison, Hull.

BANTAMS (Black or White).—First, T. Davies, Newport, Monmouth. Second, J. P. Gardner, Rugeley. Highly Commended, F. Pittis, jun., Newport, Isle of Wight. Commanded, Sir St. G. Gore, Bart.

TURKEYS.—Second, Mrs. Wolferstan, Tamworth.

GOSLINGS.—First and Second, Mrs. Seemons, Aylesbury. Highly Commended, C. R. Powys, Wallingford. Commanded, Mrs. S. R. Herbert, Powick, near Worcester; R. Rees, Abergavenny; W. K. Duxbury, Leeds.

DUCKS (Aylesbury).—First, Second, and Highly Commended, Mrs. Seemons, Aylesbury. Highly Commended, E. Shaw, Oswestry.

DUCKS (Ronen).—First and Highly Commended, Sir St. G. Gore, Bart. Second, T. Statter, Manchester. Highly Commended, Mrs. S. R. Herbert, Powick, near Worcester; J. K. Fowler, Aylesbury; W. Gamon, Thornton-le-Moors; W. Stephens, Higham Green, Gloucester. Commanded, J. K. Fowler; J. Holme, Knowsley, near Prescot; J. Robinson, Garstang.

Ducks (Any other variety).—First, Sir St. G. Gore, Bart. (Carolinias). Second, T. H. D. Bayley, Biggleswade, Beds (Grey Calls). Highly Commended, Mrs. Pettat, Basingstoke, Hampshire (Wild Ducks); Miss Clifton, Whittington, Worcester (Buenos Ayrean); J. R. Jessop, Hull (Wild Ducks); T. Statter, Manchester (Buenos Ayrean); F. W. Earle, Edenhurst, Prescot (Buenos Ayrean). Commanded, Capt. Edgell, Road, near Bath (White Call Ducks); C. W. Brierley, Manchester (Grey Calls); J. R. Jessop (Buenos Ayrean); J. K. Fowler, Aylesbury (Buenos Ayrean).

A SELLING CLASS.—First, W. Holland, Pershore (Silver-pencilled *Hamburgs*). Second, Sir St. G. Gore, Bart. (Golden-spangled *Hamburgs*). Highly Commended A. B. Dyas, Madeley, Salop (White Game); W. K. Duxbury, Leeds (Golden-spangled Polands); Rev. R. Roy, Worcester (Golden-pencilled *Hamburgs*); T. Fletcher, Great Malvern (Silver-spangled Polands); Mrs. Blay, Worcester (White Muscovy Ducks). Commanded, R. H. Nicholas, Malpas, near Newport, Monmouth (Grey Dorkings and White Cochins); J. Hinton, Hinton, near Bath (Silver-spangled Po ands); T. W. Walsh, Worcester (Silver-pencilled *Hamburgs*); T. Fletcher (Frizzled Fowls); W. Bradley, Worcester (Pile Game Fowls); J. Robinson, Garstang (Grey Dorkings and Silver-spangled *Hamburgs*). E. Pigeon (Dark *Brahmas*).

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, Birmingham, officiated as the Arbitrator.

COWS ROBBED OF THEIR MILK.

ALTHOUGH I agree with you that "J. J. T.'s" cow (see page 301), was not milked by a hedgehog, I cannot unhesitatingly conclude that the milk was taken by a hand.

My attention was lately attracted to a cow lying in a meadow by the somewhat strange posture of the animal. Going up to her to see what was amiss, I found her quietly sucking one of her own teats. She was in a wretchedly poor condition, and a countryman who stood by remarked, "She's a'most sucked herself to death."

If, as I suspect, "J. J. T.'s" cow has a similar habit, his man may convict her in the theft by looking at her mouth, even if he cannot succeed in catching her in the act of stealing her milk.—EDWARD LESTER, Borstal.

BOOK ON BEE-KEEPING.

FROM a short report in your Journal of the Entomological Society's Meeting, it appears that the letters of the *Times*' Bee-master have been condemned and deplored as full of inaccuracies and errors the most ridiculous and disgraceful. Nor is the evil which has been inflicted on the public to stop here—we are to have a "book" from the pen of that celebrated writer—a book in which if we find some truth we may also expect to find the exploded notions of our forefathers reproduced with many mistakes and blunders of the tyro.

Now for this bane, whose evil influence will be diffused far and wide, there ought immediately to be provided an antidote—and who so able for the task as the "DEVONSHIRE BEE-KEEPER?" I believe that gentleman can produce a work on bee science and husbandry worthy of the age; and if he will set himself to the task, I have no doubt he will receive the countenance and support of every British apriarian.

A book scientific and practical, embracing the most recent physiological discoveries, and all the newest and best methods

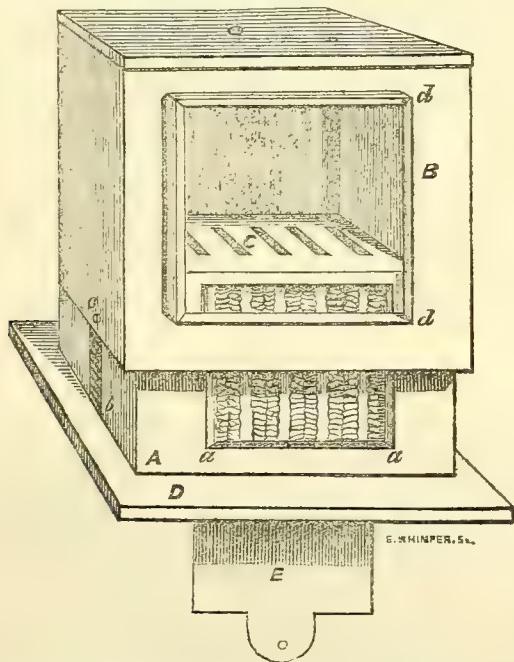

of managing bees, is a want with which the public has not yet been supplied.

Will Mr. Woodbury respond to a request which I in common with many others now make?—E. S.

BOXES AND SUPERS.

IN No. 182 of your New Series of THE JOURNAL OF HORTICULTURE, I find an article on comb-pruning by your valued correspondent, Mr. S. Bevan Fox, and in that article allusion is made to one of his hives, No. 7, a box adjuster-hive, from which in the year 1863 he took a super of 30 lbs., and in the present year, 1864, another of about 40 lbs. Now, as I am a bee-keeper, not, indeed, on a very large scale, I should be glad if your correspondent would furnish me with the dimensions of the stock-hive, and also those of a super to hold 30 or 40 lbs. of honey, likewise what must be the minimum inside measure of a wooden box-hive to contain sufficient honey to carry a good swarm through the winter.—A. K. H.

[The adjuster-hive was originally invented by Mr. G. Fox, of Kingsbridge. I gave a full description, accompanied by a diagram, of the one then in use by myself, at page 99, of No. 555, Vol. XXII., published May 17th, 1859.

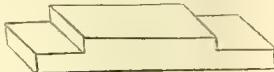

As it is possible that "A. K. H." may not possess a copy of THE COTTAGE GARDENER of that date, I here sketch out a short description of the hive, which I hope may suffice to show him the principle both of its construction and management.

The dimensions now given slightly vary from those of the previous account, but are, I think, in every way an improvement.

The stock-box A is 12 inches square, by 8½ inches deep, inside measure. It is made of ½-inch yellow deal (or ¼-inch when planed), well and truly dovetailed together, and as additional security, pinned at each corner by two pins of iron wire 4½ inches long, meeting about the centre, previously having bored with a fine gimlet. A rebate of ½-inch in depth by ¼-inch wide, is run along the upper edges of the back and front. The bars, eight in number, which are 12½-inches in length, by ½-inch wide, and ¼-inch thick, are sunk in notches of the same width and depth, so that there will be a space of three-eighths of an inch between the bars and the adapter or cover. The bars should also be constructed with shallow ribs of about ½-inch square, on the under side, after the fashion of the Woodbury ribbed comb-bar. A thin coating of melted wax should be applied to

these ribbed surfaces previous to a swarm being lived in the box.

C Is a thin board clamped at the ends, used as an adapter and top. This is fastened to the box by well-greased screws, which must be carried through the clamps only. There are two slits 8 inches long by ½-inch wide, on each side, corresponding with two of the openings between the bars. These are best made towards the two sides, leaving no communication near the centre. When the super is not being worked these slits for communication are closed by two pieces of wood about 3 inches wide, which are slipped gently along from one end to the other, so as to avoid crushing bees. The super B must be made with great nicety, just large enough in the square to slip down over the stock-box A, or about 13½ inches square, by from 12 to 15 inches in depth, according to the honey district. This is also furnished with eight bars 1½ inch in width, either formed and fixed like those in the lower box, or made of ¼-inch stuff, a piece of 2½ inches long by ½ inch deep being cut out of the top part of each end of the bar, thus—

It is hardly necessary to say that the top and adapter of the inner box must be made perfectly flush with the outer dimensions of the same.

The window in the stock-box, 7 inches in length by 4½ inches in depth, is darkened by a shutter of stout zinc, sliding upwards from below through a slit cut in the floor-board, and working in grooves covered by narrow slips of the same metal sunk its own thickness into the wood. The window in the super is of somewhat larger dimensions—say 10 inches high by 7 inches wide, and may be closed in any manner according to the fancy of the owner. In all cases of bar-hives the glass must be fitted, as nearly as possible, flush with the inside of the box.

The floor-board D is made of 1½-inch stuff about 18 inches square, strengthened by two cross pieces dovetailed and driven in tight about 4 inches from each side. It is advisable to screw the bottom board to the stock-box, otherwise it would be difficult to take off the super without lifting the inner box. The screws must pass through the cross-bars, a mortice being cut in the floor-board proper to allow of play backwards and forwards as the grain contracts or expands, according to the dryness or moisture of the atmosphere. Bee-keepers will do well to attend to this simple affair in the manufacture of all box-hives, as otherwise the sides of the box are strained and started from their fastenings; but it is particularly necessary as respects the hive under consideration.

The entrance is 6 inches long by ½-inch high, and is cut in the upper surface of the floor-board. It is contracted when desirable by moveable wedges, or by a slide. There is an alighting-board attached.

During winter, or at any time that the super is not being filled, it must be kept in its proper place over the stock-box, itself being intended to form the outer case. A moveable roof of wide dimensions is advisable. This may be made to fit the top of the super.

To work this hive the stock-hive is supplied with a swarm in the usual way. A few bits of clean worker comb attached to the bars will assist in promoting straightness of comb-building. If none is at hand the waxed ribs must be trusted to. The following season, or the same if the hive becomes well filled, the slips of wood are removed from the adapter, and the super let down to the floor-board. There will be a space of a few inches for the bees to commence operations in. Some clean guide combs should, if possible, be attached to the bars to induce them to do so. When the bees are fairly at work, and as the space allotted them becomes occupied with combs, the super should be raised an inch, being retained in its place by small blocks of wood. A rack and spring on each side used to be the means adopted for this latter purpose, but as it never seemed quite secure, the blocks of wood were substituted. As the work of filling goes on, the super must be raised little by little, suitable blocks being at hand. Two persons are necessary to effect this, and to remove the super at the end of the season. Some little exercise of judgment is requisite in deciding when these several raisings ought to be made. If delayed

too long the combs will probably be attached to the adapter, and a fracture is the consequence. If effected too rapidly, or beyond what the honey season will warrant, a quantity of empty or half-filled combs is the result. A little experience will teach the owner better than any written directions.

I have had a hive of this construction in pretty constant use for about fourteen years, tenanted by various swarms. I cannot be sure of the quantities of honey obtained from it prior to 1858. In that year a super of 30 lbs. was taken; in 1859, one of 53 lbs., of particularly beautiful honey, and in subsequent seasons it afforded results already detailed in No. 182 of the present series.

Mr. G. Fox, the summer after first stocking this hive of his invention, obtained a splendid super of more than 66 lbs. It is remarkable that only once have I ever known brood to be found in the super. This may be accidental, but I wish I could report the same of other supers.

The hive has its faults, the chief being that a bee dress is generally requisite when carrying out any of the before-mentioned manipulations, as well as an additional pair of hands when removing the super. But as a remunerative hive under the management of one who understands it, I do not believe it has any superior, if it has its equal.

With respect to the second query of "A. K. H." as to the dimensions of supers calculated to hold from 30 lbs. to 40 lbs. of honeycomb, an octagonal super of 13 inches in diameter by 8 inches deep, will contain about the latter quantity. I am very partial to shallow square supers constructed to carry the same bars, which fit into the frames in use in my frame-hives. These boxes are about 13 inches square, by depths varying from 3½ to 5½ inches, inside measure, including the bars. One of these boxes is first given, and when tolerably well filled with combs, an empty one, without the bars, is placed between the stock and the super. The combs are extended into the second box, and here is a modification of the adjusting principle at once. By this plan I have obtained some of my largest and best supers, from 54 lbs. in weight downwards.

The best dimensions for wooden stock-hives are 13 inches square by 8 inches deep. A smaller-sized box would, doubtless, contain enough stores to carry a colony through the winter; but more than this is required, there must be sufficient capacity for the breeding powers of a prolific queen, and the storing of large quantities of pollen. This being deficient, it is useless to expect the bees to confine their breeding quarters to the stock-hive; but they will ascend for that purpose into the supers. That small stock hives are a great mistake has long been the opinion of—S. BEVAN FOX, Exeter.]

BEES ARE CARNIVOROUS.

In the Number of your valuable Journal for September 20th, a correspondent, "A. W.", seems to be quite incredulous about my experience of the carnivorous propensities of the honey bee. Since then I have received a strong testimony in favour of the correctness of my theory. A lady in my neighbourhood has been most successful in preserving and increasing her stock of bees during the last three inclement seasons, when every one else in the vicinity lost all or nearly all theirs. Being anxious to know how she managed her hives, I called on her and asked how she fed her bees in winter. Her reply was, "Almost entirely on meat—any scraps of fresh meat left after our dinner, such as chicken bones, limbs of ducks or other fowls, bits of roast beef with the gravy in them, as bees like underdone meat." "Don't you put sugar or something sweet in it?" said I in a rather astonished tone. "Oh, nothing of the kind, but we are careful not to let any salt touch the meat. If there were the smallest grain of salt on it the bees would not eat it."

"And is this the way you always feed your bees?"

"Always; and my father and my grandfather never gave their bees any other food than meat, because sugar was dear in their time."

The lady lifted up a hive, and on the floor was a black crowd of bees, in the midst of which could be seen the indistinct outline of the drumstick of a turkey. The bees were evidently hard at work, though I could not exactly determine what they were doing, but they were not carrying

anything out; and my friend only laughed at my suggestion that they might so dispose of the meat.

Bees certainly attack soft fruits. I have known them totally destroy two crops of ripe Peaches, and to cause much trouble in a viney by joining in the depredations of the wasps.

Bees are very capricious in their tastes for flowers. I have a hedge of Globe Fuchsias crimsoned over with blossoms, which resounds all day long with such musical hum-ming, that I put it down as a first-rate bee-pasture; but on close examination I did not find a garden bee on the whole hedge—the songsters were all of the wild furry family. This puzzles me much. Honey for one should be honey for all. I feel rather disappointed in my Fuchsia hedge, from which I had expected great things for my bees.—RUBY.

BEE-KEEPING.

Bee-keeping. By "THE TIMES" BEE-MASTER. With Illustrations. London: Sampson Low & Co.

This is a superfluous and jesuitical book—superfluous because it contains nothing useful that is not to be found in recent cheaper works; and jesuitical, because whilst it professes to obviate "the obscurity and complexity of bee books in general," all its practical portions are pure and simple extracts from those very books. That our readers may judge for themselves on this point it will be sufficient to state, that the body of the volume contains 224 pages; of these nearly 50 pages are a reprint of the letters in the *Times*, and more than 70 pages are verbatim extracts from the works of Bevan, Taylor, and others. Not 30 pages are original.

We take leave to correct one of the many unfounded and reckless assertions in which the writer indulges. In page 142 he states that Mr. Woodbury has "patented" a hive, and insinuates over and over again that that gentleman exposed the Bee-master's errors because he did not notice this hive. It is more than probable that every apriarian reader of this Journal knows this assertion to be untrue, and will disbelieve the ungenerous insinuation: nevertheless it may not be out of place to mention that to our certain knowledge Mr. Woodbury has no pecuniary interest in the sale of any of the hives which have been named after him, nor has he ever benefited, or sought to be benefited, a single penny by his apriarian inventions.

With two further observations we leave the volume. We have no intention to criticise the *Times* for rejecting Mr. Woodbury's reply to the "Bee-master's" letter; but the "Bee-master," acting as judge in his own cause, says that reply was rejected "very properly." We must therefore observe, that at the Entomological Society, "Professor Westwood and the Rev. Hamlet Clark (two disinterested judges), regretted the diffusion of so much error in a leading journal, and the unfair treatment to which Mr. Woodbury had been subjected."

Lastly. The "Bee-master" recommends a lady, if she finds a toad in her apiary, to "empty on him a snuff-box full of strong snuff," adding, as if it was aocular treatment, "he will reflect a few days before he returns to his old quarters." Now, we ask of our readers, whether ladies or gentlemen, not to adopt such a cruel treatment, for it insures torture and a lingering death to the toad.

BEES, BEE-HIVES, AND BEE-MASTERS.

On Tuesday the 11th inst., a lecture on the above subject, being the first of the winter course of lectures in connection with the Liverpool Young Men's Christian Association, was delivered at the hall of the College, Shaw Street, Liverpool, by the Rev. J. Cumming, D.D., of London.

The Rev. R. W. Forrest presided; and after calling upon the Rev. Mr. Forfar to open the proceedings by a prayer, briefly introduced the rev. lecturer, remarking that they must all be much surprised at the versatile talent of our lecturer, whether discoursing about the Pope, or descanting upon the economy of the little insect which he will bring before our notice this evening.

The Rev. J. Cumming, who was enthusiastically received by the very large audience that thronged the hall, said they would no doubt be surprised at the subject announced for

their consideration this evening. He said, The truth is, I am accustomed to spend the summer months with my wife and children at a cottage in Kent, where for the last fifteen years I have sought out amusement, in hours that I could spare from those duties that devolve on me as a minister and teacher of Christ, in attentively studying the economy of the hive; and my lecture to-night will therefore be the result of my personal experience of the habits of bees. Some of you will perhaps say, "Dr. Cunningham must have a bee in his bonnet, and but occupies his time for the moment with them." I have read few books on the subject; but I have twelve hives, some of which have glass windows and some have not, the bees in which know me so well that they would rest on my hands, face, and hair, and not one of them dare to sting me. I often sit for hours watching my bees, and when I observe anything interesting or unusual in their proceedings "make a note of it."

Virgil has given an account of bees in one of his Eclogues; but by far the most attentive watcher was the blind entomologist, Huber. I do not think that apiculturists have succeeded in bringing any new facts to light, or noting anything concerning their habits which he (Huber) did not.

The component parts of a hive are three—workers, queen, and drones—not three different kinds of bees, but three different species.

Workers.—The worker is a little tiny insect, with four wings, and beautiful colour on its body. All the work of the hive is divided amongst the workers—some of them collect honey—and it is a curious fact that the bee never goes from flower to flower, but picks out a flower—thyme, borage, or clover—and keeps to it)—some collect food for the young grubs, some act as guards to the hive, to keep out intruders; and there are others whose duty it is to ventilate the hive. I can play with my bees, and take a swarm in my hand; but if a stranger approaches the hive the guards instantly fly at him. But I think the most curious thing in the economy of the hive is its ventilation—four or five bees go to the mouth of the hive, and, using their wings as fans, by moving them backwards and forwards, keep up a cool current of fresh air through the hive. It is worthy of notice that, if a bee-master, in order to ventilate his hive, cut a hole in the top of it, the bees immediately cement it up with a wax-like substance which they collect, and which is called "propolis." From this we may learn that, while ventilation is necessary to healthy life, draughts are hurtful.

Queen.—The queen is twice the size of the common bee, and is the most elegant creature you could imagine—you would take her for an empress. Queen as she is, she springs from the ranks. The previous queen lays precisely the same egg in the royal as in the common cells, but the young princesses are fed with a peculiar kind of food called "royal jelly." If the queen dies, and there are no princesses, the hive falls into a state of anarchy, and one of three things will usually happen: either the bees will all take flight and perish, or pine away and die, or, more frequently, if there is a very young worker grub in the hive, they enlarge its cell and feed it with "royal jelly," and it in due time becomes a perfectly developed queen. I have seen the queen going round the hive giving instructions with twelve or thirteen ladies in waiting, who—this is a well-known fact—never turn their backs on her majesty, exactly like our own Queen's court. Bees are very fond of strong drink, particularly Scotch ale. Whiskey and brandy they will not touch, but give them rum with sugar in it and they will sip it up eagerly. The only time I ever saw bees turn their backs on their queen, was in a weak hive to which I had given some rum medicinally, and they all drank to excess, and, her majesty included, became intoxicated and tumbled about the hive. They eventually became so excited that, though November, they attempted to swarm, but as soon as they felt the cold wind outside they returned to their hive.

Drones.—In a good hive of about 20,000 bees, there are from 1500 to 2000 drones. There is no such thing as polygamy among bees. The queen selects one to be her husband, and he remains so until he dies, when she does not take another but remains a royal widow. You will ask, What then is the use of so many drones? I have made a discovery which has led me to adopt a theory, which has been opposed by many able apiculturists. The temperature of the hive in the breeding

time (for I have thermometers in some of my hives), ranges from 90° to 95° Fahrenheit. The drones remain in the hive during the cool morning until twelve o'clock, when they go out and enjoy themselves for an hour, and then remain in during the evening. The only time when this high temperature can be kept up naturally is in the middle of the day, and during the months of June, July, and August, before which time the drones are killed. Drones, therefore, keep up the requisite temperature of the hive. They are lazy, idle, good-for-nothing fellows, and when the queen has selected her husband begin to sip the honey. When the workers perceive this they drive them out of the hive. Hundreds, I may say thousands, of times have I seen a little worker garotte and by sheer force throw out of the hive a great burly drone.

Hives.—In Kent, the peasantry use the common straw hive, and I have little doubt they do the same thing in Lancashire, suffocating the bees with sulphur when they want to obtain their stores. This is a most foolish proceeding, as besides destroying the stock, it utterly ruins the honey, by filling it with poisonous sulphurous acid vapours. It is very wicked, too, and I consider beecide next to homicide. I use Stewarton hives, and from ten by the depriving system I this year obtained 212 lbs. weight of pure virgin honey, leaving the bees about 150 lbs. for their subsistence during the winter. I am not a honey-seller, but had I sold this to Messrs. Neighbour & Son, I could have obtained 2s. 6d. per lb. for the best, 2s. for part, and 1s. 6d. for the remainder. I make it a point never to kill a bee; but if I kill one accidentally, so good a memory have they, that for two or three days they would sting me did I go near the hive. If any of you have bees in a straw hive full of honey, my advice to you is, Do not suffocate the bees, but when most of them are out, about twelve o'clock, take a knife and firmly and fearlessly cut a hole in the top of the hive of about 3 inches in diameter. Have a board with a similar hole ready to put on the top of the hive, and on it place a bell-glass, put a nightcap over the glass to keep it warm, return in three or four days, and you will find the glass full of pure virgin honey. There is no prettier object on a breakfast-table than a bell-glass full of honey, and a very much better thing it is than fat bacon. Those who eat honey to breakfast always have sweet tempers. There are three kinds of hives in general use—the Ayrshire or Stewarton-hive; the collateral, but I do not think it so useful as the former; and the nadir, from nether, or lower. One great law is to make the hive as little tortuous as possible; my idea is, the plainer the more successful. Every cottager should keep bees, they will pay the rent, if he only have six, seven, or eight stocks, which will nett £8 to £10 per annum. If any of you are going to begin keeping bees, I would be happy to give any advice in my power.

Swarms.—If you do not give the bees room they will swarm; the swarm is always headed by the old queen; 10,000 or 15,000 bees rush out at once—some say they send out scouts to fix upon a place for alighting—and form a cluster with the queen in the centre, exactly like a bunch of grapes, 7 to 9 inches long, and 3 or 4 inches in diameter. Swarms always take place between twelve and three o'clock. A princess arriving at maturity either causes a swarm, or else the rival queens fight until one of them is killed.

Enemies of Bees.—Wasps.—Every one in the country must have observed the unusual quantity of wasps this year. They dash into a hive, and take a sip of the honey, until the bees collect together, and drive them out. I generally offer 3d. or 4d. for each wasp's nest destroyed in my neighbourhood. I know of no more useless insect. He lives by thieving. I often put a piece of barley-sugar about 6 inches long at the entrance of the hive. The bees are so fond of this that they collect together in sufficient numbers to resist the wasps. **Spider.**—This is a great enemy of the bee. If a bee gets entangled in its web, nothing can save her. I have found it impossible to take its adhesive threads off her legs without mutilating her. The best remedy—a hard crush—and often used. **Tomtit.**—This little audacious bird will in winter fly on to the alighting-board, and knock at the door, and gobble up the first bee that comes out to see what is the matter. **Death's-head Moth.**—This is another troublesome enemy of the bee. The best remedy is to narrow the entrance so that it cannot get into the hive. **Snails.**—Snails

are so fond of warmth that they will crawl up the support of a hive, and sometimes get into it. The bees are powerless to sting them; but on one occasion I noticed a snail get into one of my hives, and after trying various expedients, the bees actually built it up all round with propolis until it was suffocated, and then let it remain in its sarcophagus, as it caused no smell. But the bee's greatest enemy is man with sulphur.

Bees are very kind to their sick or wounded companions. They will take a wounded bee on to the alighting-board in the warm sun during the day, and lick it, take it in at night, and bring it out in the sun on the following morning. Bees are early risers, being at work by daylight, and they never work after four o'clock in the afternoon. They are very tidy and cleanly—you have no idea how often the hive-floor is swept out. None are lazy but the drones. They are very loyal, defending their queen from all attacks. They are not pugnacious; their stings are only used in self-defence, as they know that as their sting remains in whatever they attack, they are sure to die after it.

A vote of thanks to the reverend lecturer concluded the proceedings.—EATON CLIFF.

[For the correction of many of the mistakes made by the rev. lecturer, we refer our readers to Mr. Woodbury's two letters in pages 140 and 141 of our present volume, but we cannot refrain from noticing one or two additional blunders.

Surely Dr. Cumming must have been very unconscious of what has been passing in the aparian world during the present century, when he hazarded the assertion that no new facts had been brought to light by aparians since the days of Huber. Is parthenogenesis in the honey bee no new discovery? and can he possibly be ignorant of the numerous facts investigated and proved by means of the Ligurians—such as, for example, that bees do not always return to their own hive, nor are they invariably slaughtered when they attempt to enter a strange one; also that Huber was mistaken in dividing worker bees into two kinds—viz., nurses and wax-workers, the fact being that both are identical in every respect except age? Huber has also been proved wrong in other particulars, such as his statement that bees will invariably accept another queen at the expiration of twenty-four hours from the loss of their own, and that workers will at no time attempt to employ their stings against a stranger queen.

A queen bee is not nearly so graceful and elegant in form as a worker. Although she is ordinarily treated with great attention and apparent respect, no special "ladies in waiting" accompany her; nor does she ever give "instructions," for the duties of the hive are carried on with perfect regularity during the interregnum of the swarming season, and whilst her majesty is absent on her nuptial excursions.

If the lecturer had read even Huber with attention he would have learned that there is sometimes such a thing as polyandry (not polygamy) among bees; and if he were aware of what is passing around him he would have known that this fact had been confirmed by more recent observers.

When Dr. Cumming commences with "I have made a discovery," we may be pretty sure he is about to resuscitate some long-explored fallacy, and this proves to be the case with his theory in respect of drones. We need hardly say that the queen never "selects" a husband, neither is a single worker anything like a match in point of strength for "a great burly drone," unless the latter has been much weakened by exposure to cold or starvation.

It is tolerably evident, also, that the lecturer has never seen a large, or even an ordinary-sized swarm, or he would have doubled his numbers, and trebled or quadrupled his measurements. It must indeed be but a poor swarm that on a hot summer's day forms a cluster only "7 to 9 inches long and 3 or 4 inches in diameter!"

What a lazy race of bees the doctor must possess if they "never work after four o'clock in the afternoon!" Truly they would appear to have joined the "nine-hours' movement," and we fear we may yet learn, on the lecturer's authority, that they have resorted to trades' unions and paid emissaries, in which case we may congratulate ourselves on being at such a distance from him that our bees are likely to escape contagion, and continue working as heretofore all summer through till darkness compels a cessation of their labours.

Seriously, we think it a great pity that Dr. Cumming should attempt either to lecture or to write upon a subject regarding which he knows so little. Compliments on his "versatility," and the "thanks" of town audiences who in this particular are necessarily ill-informed, may be gratifying to his vanity; but his evident want of information with regard to bees must make the judicious grieve. Occupying as he does no mean position in the very highest and holiest of professions, he might surely leave aparian science (to which, as he most truly says, he has contributed nothing whatever), to be taught by those who really understand it.]

COOKS, COOKERY, AND WILTSHIRE BACON.

MAN is a carnivorous animal, also an herbivorous, also a frugivorous, also—for I might possibly add another "also"—what does man not eat? The earth, the sea, the mountain, the plain, are alike ransacked by him for food; but flesh is not good when raw, nor vegetables nice when not cooked, and fruit, although pleasant enough to the palate as plucked from the tree, is improved after having been submitted to the action of fire. Witness an apple-dumpling—a dish fit for a king. Why, did not its very manufacture cause wonder to arise in the breast of George III.? in honour of which event it ought to have been called "King's dumpling." As James I., at the banquet at Houghton Tower, near Preston, is said to have knighted then and there a loin of beef, so "farmer George" should have taken the wonderful dumpling under kingly patronage for ever.

Now, it seems, possibly by accident, that man in very early days cooked his food; he became, or found, a cooking animal. How does this matter stand now that the world is in round numbers some six thousand years old? We will in our investigation of this subject go no further than our own country. Well, in every cottage cooking is going on at some time of each day, usually in the evening, for although the labourer and mechanic may do with bread and cheese, or a slice of cold bacon and bread, at their brief meals in the day, yet they naturally, when they come to sit down and feed in earnest, like a hot supper. Cold food may do in the daytime, but hot bacon and potatoes or greens and hot pudding at night. Then, again, cooking is going on in the mansion all day long; cooking for hot breakfasts, for lunch, for dinner, besides preparing all sorts of things to come in at future times. In houses of the middle class cooking occupies even necessarily a great deal of thought and time. Now, who, as a rule, is cook? Well, we reply, women, though with a full recollection of male cooks rushing across our old college court at Cambridge, white-aproned and white-capped. Yes, as a rule, woman is the cooking animal. Among the countless thousands of benefits and comforts coming to us from woman's presence in the world stands this—she cooks for us. And now for a little homily upon this subject of cooking.

I am sure it occupies too much thought and time, infinitely more than it did when our fathers were in our places. We are grown very heathens, and the first question practically asked in our houses is too often, "What shall we eat and what shall we drink?" with this commentary, let the most luxurious viands be prepared in the most luxurious way. If asked to give an example in proof of the extravagance of the age, I would point to the increase in cooks' wages. A good old body, cook in old days in a mansion well known to me, had but £14 a-year, and managed to save a fortune out of it. One of her successors had £40 per annum. Cooks now can get any wages, they are the only servants who can rapidly make money. As to governesses, why the cooks would not change places with those poor young ladies—of course not.

Then, look at the alteration in respect to the dinners. They used to be plain and good, roast and boiled, with a side dish or two. Now, in the same house are side dishes by the dozen. Hence it comes to pass—how intolerably long dinners last!—you sit down at half-past seven, and finish possibly at half-past nine, then dessert; and so the whole evening is consumed in gourmandising. People give dinner against dinner, side dish against side dish, vieing as to excess and richness of food; they talk of having had "such a feed at Mr. Plutocrat's." What animals! their horses would use the same words if they could but talk.

Now, from these lengthy dinners it follows there can be no intellectual games, such as Canning loved; little or no time for music or anything rational. I once heard of three maiden ladies whose evening entertainments were termed "bohea, prayers, and turn out." I would say that some modern dinners are, "cram, Guzzle, and turn out." People meet not so much for pleasant intercourse as for glutony. The world began to go wrong when dinners were later than six o'clock. England has been on the decline ever since.

The demand for cooks is something tremendous. Letters from friends continually have this—"P.S. Can you send me a good cook?" The moment one meets a friend, after hurried, very hurried, inquiries after one's health and family, out comes the all-important subject, that of a cook. I had an amusing instance of this cook-demand a little time since. I was at a railway station when a clerical acquaintance caught sight of me, his looks, his gestures, his rapid run across the line bespoke, so I deemed, his great regard for me. I thought, "Ah! the world is not heartless after all, here is a man I hardly know, so pleased to see me. Here he comes rushing foward to shake hands." Judge of my disappointment when, breathless and panting as he was, out came the old question. "Can you tell me of a good cook? Mrs. A. is distracted for want of one." Now-a-days it is not, "Oh, for a poet;" but "Oh, for a cook."

The son of a gentleman married his father's cook. Why did he do so, what could be his reason? She was not beautiful, she was not rich, though her pie-crust might be. At last a sensible matron, not unfrequently the troubled mistress of a cookless kitchen, suggested—"I think he did it to secure a cook; I can't secure one. The man was right, now he will be sure to keep his cook."

In olden times young ladies had a carving master as well as a music master, it was not a bad idea. Why should not our young ladies take lessons in cooking? Rely upon it, the best mistress is the one who knows how work is done. I would say, a lady who became a proficient in the art should have a medal or a certificate, and it should be shown to the gentlemen after dinner. I think it would be a kind of marriage qualification. Besides, if all the cooks in England should strike, as the London cabmen once did, and cooks have become very independent, then with lady cooks as a resource we should not starve.

Now, although I thus rightly, for so I think, rail against extravagant cooking, or too much cooking, yet as long as the world lasts there must be cooking, and cleanly wholesome cooking is ever to be praised, and he that helps me to eat health-giving food does me a favour. I would say then, every one ought to eat a good breakfast. If he does not he cannot do a good morning's work, and the morning is the best part of the day. Further, many have a poor appetite for the morning's meal and just nibble a bit of toast and drink off a cup of tea. This is not the breakfast to work upon, it only ends in faintness at ten o'clock, hunger at half-past ten, and a splitting headache the rest of the morning, besides, perhaps, a tendency to irritability the whole day. Now, the working man in order to work well with hand or pen in hand must make a good breakfast. If he has naturally a bad appetite it must be tempted, and nothing for this purpose is equal to bacon, more particularly and especially Wiltshire bacon.

Just in passing let me say that potted beef is, I find, a good tempter to a sickly appetite, and let me just drop a hint about its manufacture. It is often too dry and hard, rather resembling semi-conjoined pellets of tow out of a boy's popgun. Now, to remedy this, next time have beaten up with the beef a bit or two of boiled bacon, then you will have an improvement in flavour, and its consistency will be that of a nice smooth spreading paste to cover your toast with.

As to bacon I cure my own. I manage in this way. I buy a little pig in May; he is destined to die, weighing eight score, in October or November, according to the weather. This I call my summer pig. In August I buy a second, for I have two sties. Thus I have two pigs at the time of the year when there is an abundance of green stuff in the garden of no use but to throw over to the pigs. Hoofs and stomach do their work in producing plenty of manure for my garden. By the time the first pig is killed the second has become a strong fellow. N.B.—It is of no use to have a very little

pig during the winter, he cannot stand the cold, but by having him a good size before the winter he goes on bravely.

Well, I kill this pig in March, never if possible exceeding the eight score. If more, pigs are too fat and there is waste; if smaller, the bacon is too thin. Thus I go on year after year. I would say, that the country parson who does not keep a pig or two has a lesson to learn in economy. If I gain nothing—but I do gain—still the garden gains. Besides the flavour of pork depends upon the food on which the pig has been fed: hence, a wholesomely-fed pig is doubly valuable, into whose mouth has passed nothing but good vegetables, bran, meal, and sharps.

As to the curing, I manage that in a tray made of beech wood 4½ feet long by 2 feet wide, and half a foot deep. One particular precaution is, to have a hole made in one corner to let the brine run off, in that lies the secret of good bacon. At the end of six weeks take out your fitches, rub them with bran, and putting them in bags, hang them in your kitchen. Then begin on them, let rashers be cut very thin and be only just done, once made a dry frizzle and all is ruined—flavour, wholesomeness, relish, all gone.

I have said nothing of the grand killing day—the charms of pig's fry, griskin, spare-rib, chine, even hams must go unsung. Pigs have one great vocation in life, at least in death—viz., to make bacon, and those who like not rook-pie, yet like well rashers of bacon. How they grace the breakfast-table! How pleasant to say, "My own feeding I assure you, no fear, do take a piece;" and to get after a few minutes the words, "How very nice, what a breakfast I am eating!" As to myself, I rise with no fear of getting faint, nor of being irritable. I do a good morning's work, perhaps I even write a paper for "Our Journal." One last word upon the sort of pigs. I prefer the black Berkshire breed chiefly. I had once two at the same time, one black the other white, we called them "Gown and Surplice," but "Gown" fairly beat "Surplice," and so black became the established colour at Hilltop Rectory. My dog is black, my Bantams are black, and my pigs are black, the colour is consistent throughout.—WILTSHIRE RECTOR.

OUR LETTER BOX.

WEIGHT OF BUFF COCHIN COCK (C. S.).—As it weighs 8½ lbs. at twenty-two weeks, and, if it goes on at the same rate, it will weigh in December nearly 11 lbs. Quite large enough for exhibition.

POINTS IN NANKIN BANTAMS (A Poultry Fancier).—The hens should be buff coloured all over, save the tail feathers, and a darker shade on the hackle. The cocks should be red all over, except the tail; they should have blue legs, and be very small.

COLOUR OF BLACK-BREASTED GAME BANTAM'S LEGS (R. J. W.).—Any colour is admissible for the Bantam's legs. Willow are the most esteemed. The cocks should be dubbed as late as possible, but before they change feathers. If dubbed too early the comb grows, and a second operation is necessary. Say from five to six months. They cannot weigh too little.

BOOK ON FOWLS (Cornwall).—"The Poultry Book," by Wingfield and Johnson. It is out of print, but copies may be found occasionally at the dealers in second-hand books. It has superior coloured portraits of prize birds.

BRAHMA POOTRAS (Idem).—We are perfectly convinced that they are only a variety of the Shanghai, or a cross between that and the Malay.

BEES ROBBED BY BEES (S. M. C.).—The best mode of preventing further mischief is to elude the attacks by temporarily removing your bees to a distance of not less than a mile, or a mile and a half. In a few weeks' time they may be safely returned to their old positions. Narrowing the entrances, so as to admit of the passage of only a single bee, will enable the besieged colonies to offer a more stubborn resistance; but a short term of transportation is the most effectual remedy.

EARWIGS IN HIVES (A Lover of Bees).—Earwigs in hives are of course a nuisance, but we have often found them stray into really strong colonies, and never could perceive that they did any serious mischief. Messrs. Neighbour & Son, 149 Regent Street, and 127 Holborn, manufacture Payne's and every other description of bee-hive, and will state prices and furnish catalogues on application.

BEES FROM A DISTANCE (T. S., Surrey).—If the bees come safe to hand they had better be permitted to remain in their original hive until spring, and then be allowed to swarm naturally. In the event of a smash, which is far from improbable, the box and combs may yet have to be resorted to, but in this you must be guided by circumstances. A transfer so late in the year would at the best be very hazardous. With regard to the necessary supply of pollen much must depend on the character of the remaining months of autumn and the approaching winter.

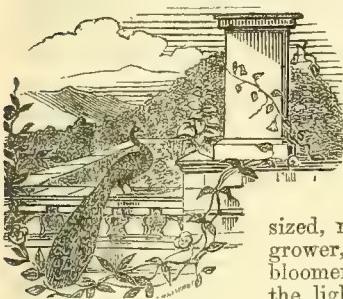

TOMATO SAUCE (G. J. N.).—Stew six tomatoes in an oven till quite soft take out the pulp with a teaspoon, and add cayenne and vinegar till of the consistence of thick cream. Italian.—Take five or six onions, slice and put them into a saucepan, with a little thyme, bay leaf, twelve or fifteen tomatoes, a bit of butter, salt, half a dozen berries of allspice, a little Indian saffron, and a glass of stock; set the whole on the fire, taking care to stir it frequently, as it is apt to stick. When you perceive the sauce is tolerably thick strain it like a purée.

WEEKLY CALENDAR.

Day of M'nth	Day of Week.	OCTOBER 25-31, 1864.	Average Temperature near London.	Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.
25	TU	Golden Plover appears.	Day. 55.9 Night. 38.9 Mean. 47.4	Days. 18 m. 44 af 6 h. 45 af 4	m. 15 h. 1	m. 32 h. 2	m. 25	m. 15 h. 53	299

30	SUN	23 SUNDAY AFTER TRINITY.	55.1 38.4 46.7	18 53 6 35 4	36 6 28 4	●	16 15	304			
31	M	Woodcock arrives.	53.9 38.3 46.1	20 54 6 33 4	43 7 1 5	1	16 17	305			

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 51.7°, and its night temperature 37.5°. The greatest heat was 67° on the 29th and 30th, 1833; 31st, 1834; and 23rd, 1860; and the lowest cold, 23°, on the 29th, 1843; and 26th, 1859. The greatest fall of rain was 1.06 inch.

WHITE ROSES.

HAVE read with interest the article of "D." at page 290. I agree with him that we want new pure white Roses. The best I know of are Madame Zoutman (summer Rose), full-sized, nearly white; a strong grower, and a great and good bloomer. It is the best of all the light summer Roses, just

as Paul Ricaut is the best of the coloured summer Roses. The best Roses of white tendency with good attributes are H.P. Madame Freeman, pure white and of excellent shape, and a good grower here; Bourbon Acidalie, and the two Tea Roses Devonensis and Sombreuil. The last is here a very healthy hardy plant on the Manetti stock. I never protect either of them more than I do Hybrid Perpetuals. The above five are the best, taking all points, and are suited to most soils. Madame Alfred de Rougemont, an excellent grower and a great bloomer, and Emotion, lovely, are both too small. Virgin requires a wall and very good soil. Louise Darzins and Louise Damaizin I do not possess. Louise Martgottin as exhibited in London appeared to be of a novel and lovely colour, not white but tender flesh, and not of sufficient substance in the petals—a matter too much overlooked.

We want Roses of pure white like Princess Clementine (a flower which soon falls), and of the substance of Acidalie and Madame Zoutman. Madame Freeman is the best I have seen lately. Mademoiselle Bonnaire is lovely, but it is not white nor a very good grower; it is white with a delicate rosy centre. Sœur des Anges is often cracky, but it is a full-sized Rose, rosy flesh in the centre, and occasionally magnificent. I have twelve plants of it together. It is a good grower. To prevent crackiness, perhaps it would be well to take up the plants every year and root-prune. By thinning the buds I obtained some magnificent specimens. If this does not succeed, probably destroying all the first buds would cause the plants to send up single buds, which, with abundant watering in sultry weather, would produce more perfect and free-blooming buds. I shall remove my plants in the spring and practise my suggestions.

As regards Madame Vidot and Madame Rivers, it is to be regretted that they are somewhat delicate and uncertain. The former, as a flower approaching white, has not yet been beaten. The finest Roses of light colour here are Souvenir de la Malmaison and Duchesse d'Orleans. They are both magnificent here, and good and abundant bloomers. The former is on its own roots and on the Manetti stock, against a south wall; the latter is on the Manetti only, and in the open. Taken at all points, for two seasons Duchesse d'Orleans

has beaten Sœur des Anges; still I have occasionally grown a bloom of the daughter that has eclipsed the beautiful mother. They are both more suited for autumnal blooming than to the early part of the year. That is the case with the following Roses in other colours—namely, Auguste Mie, Souvenir de la Reine de l'Angleterre and General Washington—all grand Roses. Such Roses are very useful after others have done their work.

I shall be very much obliged to "D." if he will give us further information. Can he tell us anything of Madame Macker? I see that the Roses of 1864, which I selected by prophecy, have turned out to be the best—viz., M. Victor Verdier, La Duchesse de Morny, Eugène Verdier, and Pierre Notting. The last I did not name, as nothing was said of its form. Alpaide de Rotalier is well spoken of. Of this and the first two I have nineteen nice plants. The best new Rose I have seen lately is Lord Macaulay. The best seedling, likely to be a very good Rose, is in my opinion Dr. Lindley. It is of great size, excellent substance, and very dark.

I saw at Mr. Keynes's lately an admirable bloom of Paul Desgrand, brilliant crimson, and globular. Laurent Descourt as an ornamental Rose will be a great favourite. I began with white and have ended with purple.

Rushton.

W. F. RADCLYFFE.

P.S.—The blooms of new Roses sent to me for inspection were Lord Herbert and Lord Macaulay. The best that I saw in London were Lord Clyde and Monte Christo, a delicate grower. The best of all was Charles Lefebvre.

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 2.

RETURNING to one of the midland counties with my book of dried impostors, I showed it one day to the late Mr. Bree (after whom the *Lastrea Fœniseii* is called "Bree's Fern"), bewailing to him the difficulty I had in naming truly the specimens I found, with no other help than that given by books.

Mr. Bree did not say, as he might have done, "It's your own ignorance," but in his own kind way he gave me a bit of advice that has helped me more in my searches than anything I have read in books. He said, "Yes, it is always a difficulty to beginners; but the best way is to make yourself thoroughly acquainted with the looks of the true Fern before you hunt for it, and in difficult varieties to try and get a frond, so that you may match it;" and, in order to help me further, Mr. Bree sent me a number of fronds, such as *Lastrea Fœniseii*, *L. cristata*, *L. rigida* (found by Mr. Bree at Ingleborough, in Yorkshire), *Polypodium phegopteris*, *P. calcareum*, &c., to take about with me till I had either found their fellows or learned the true notes of their speciality. Of *Polystichum lonchitis* there was only one true plant in my immediate neighbourhood, and this had but three fronds, so I had to make it a morning call and learn its features as best I could.

Furnished with my book of "patterns," a black tourist's bag, two trowels, one flat like a bricklayer's, to pick Ferns out of rock or wall, I set off on a Scotch tour. I was provided with all the requisite means of collecting the Ferns; but how was I to carry them about for two or three months in any quantities? I hit upon the following plan which answers so completely, that I think I may say I have hardly lost one specimen since I adopted it, and I have brought Ferns from the very heart of the Pyrenees.

I provided myself with a large tin box with padlock and key, and three or four yards of common brown calico. As I found the Ferns I wrapped them up in bits of calico with a little earth and drainage at the bottom, sewing them tight, like little mummies, leaving only the fronds and stalks uncovered. In this way the tin box held large quantities. At the inns I simply unlocked the box, and once in every few days sprinkled them with water. I have carried them in this way for two or three months. They are not half the trouble of a new bonnet, for they come out at the end of the journey as fresh as when they started, which I grieve to say a bonnet never does.

Our first halting place was Edinburgh, and early morning found me wending my way through old dingy streets, past houses of a dozen stories high, to Arthur's seat, where in some retired nook I was told I might find *Asplenium septentrionale*. Ever and anon, as I walked, I turned to gaze. Below me lay the fair Palace of Holyrood with its ruined graceful chapel and its thousand associations. There Rizzio was murdered. There the beautiful but hapless Queen Mary sinned and repented. There the Pretender slept—Pretender indeed! Instinctively I hummed the old Jacobite toast, ending—

"But which Pretender is, and which the King,
Why, bless us all, that's quite another thing!"

Away to the left in the old town is the Tolbooth, and a little further the Canongate, places that seem to come to you as scenes of your childhood, so familiar have the wondrous pages of Sir Walter Scott made them, and as one toils up the steep ascent to Arthur's seat a crowd of old memories rush in upon the mind, and the eyes become a little blind to the direct object of the walk. What wonder, then, if you return, as I did, Fernless, but with an appetite as keen as a hunter's from the pure air sweeping to you over the white-capped waters of the Firth of Forth?

My first personal acquaintance with *Dryopteris* (I must be allowed to use their Christian names!), in its wild state, was made between Haworthden and Roslin, in a lovely walk raised a little above the flowing rippling Esk. In the woods on either side it grows in great luxuriance, and many a root found its way into the black bag. It gave rise to a great argument, one of the party declared it to be *Calcareum*. In vain I said *Calcareum* had not as yet been found in Scotland; in vain I pointed out the true characters of *Dryopteris*, the pale green of the young fronds with their three little rolled-up balls, the flat compact forms of the larger fronds, descending meanwhile on the blue green of *Calcareum* with its larger more straggling fronds, its narrower pinnae, its sharper serrated pinnules. It would not do, and, doubtless, to this day the same Fern bears two distinct names in our respective ferneries.

Dryopteris is a little difficult to pack from its creeping roots; but I was unmerciful, cramming a whole heap of delicate little fronds and roots into one mummy case, and of all my transplanted Ferns *Dryopteris* stands second in its free growth and increasing habit; but it should be planted as a border to a fernery amongst the lowest stones, and never in the upper stages as it soon overgrows any Fern near it. It looks well in contrast with *Asplenium trichomanes*. I found *Dryopteris* very plentiful all over Scotland; but in Fern-hunting I make a rule always to take the first specimens I find. It is easy to change them for finer plants afterwards, but Ferns are usually very local, and an opportunity neglected is oftentimes an opportunity gone for ever.

My next acquaintance with *Dryopteris* took place at Callander, where a tourist is first allowed the privilege of saying he is in the highlands. Callander is a famous place for a few days' halt, for there are good fish in the river, and the country around abounds in wild flowers and Ferns. It is a pleasant little village of scattered white houses, backed by Fir-clothed rocks, while in the front and to the right are

undulating hills leading up to the foot of Ben-ledi, or the "Mountain of God," where shadows are always dwelling. I was told I should find *P. lonchitis* on Ben-ledi, but I searched there in vain.

Within a walk of Callander are the Falls of Brachlinn, to which we were guided by a shoeless intelligent child of the mountains, carrying our basket of provisions, which we ate on some scattered rocks within sight and sound of the merry leaping waters, which fell at our feet with a rushing mighty music. It was just the home for *Hymenophyllum tunbrigense*, and little Maggie and I jumped from boulder to boulder in fruitless search; but roving amongst the débris of leaves and moss I found a whole carpet of *Polypodium phlegopteris* and *dryopteris*.

I have noticed this peculiarity in *Phegopteris*—it chooses shade for its roots, but the fronds make their way through tangle and briar up to the light and sunshine; and to do this the wiry stalk is often half a yard in length, so that sometimes it is no easy matter to get at the roots, and I chose rather the plants where the fronds were less fine and the stipes shorter. These, usually, were near at hand on drier soil.

Phegopteris is not so happy-looking in cultivation as *Dryopteris*, and it is even more troublesome to pack. I took up a large surface of roots, sewed them in a flat package and put them at the bottom of the box with the other Ferns upon them. In this way the fronds were injured, but the roots themselves were unharmed. About Callander I found my first *Cystopteris fragilis*—that loveliest of all our English Ferns—so easy of cultivation, so delicately varied in form, and yet so tenacious of life that the smallest division of the bulbous-looking roots will grow. I do not think sufficient attention has yet been given to this Fern.

I have in my collection many true and constant varieties, for which I can find no name in books, one of these and the most beautiful in its diminutive grace is hardly 3 inches in length. The pinnae are nearly opposite each other, and are in the lower pinnules thrice-pinnate, the whole of the divisions are acute, and this separates it from *C. alpina*, as also from *dentata*. I have other varieties equally distinct, and coming up year after year true to their original form; but I did not find these at Callander, though all the old broken walls abounded in the usual form of *C. fragilis*, and I brought away dozens of plants in their compact mummy cases.

My first Scotch "Sabbath" was passed within the shadow of Ben-ledi. How different it was from an English Sunday, and still more from an Italian *jour de fête*. A deep solemnity seemed fallen on the world, the very mountains looked a shade more green, and the wild flowers as if they blushed at looking so pretty, and growing on this sober day. I went to the "established church," from which the "Free Kirk" has fallen away, just as the "Southerners" fall from the "North," which in like manner fell from its allegiance to England. The humble building was filled with a sober severe-looking congregation. The minister and Kirk session were in the vestry electing three "elders," of which notice was given to the congregation, and if any had objections to raise they were cited to appear and state them. Presently the minister came and gave out a psalm, which we all sang sitting down, then he made a little quiet prayer, all the congregation standing, then we sang again, after which there was a sermon with nothing particular in it, then another psalm, then the elders were addressed and vowed obedience to the "confession of faith." After this the congregation were addressed relative to their duties to the elders. A very onerous post these elders seemed to fill! Verily, if they did their duty and interfered with their sinful brethren as they were bidden to interfere, methinks the old-established Church of Scotland would deal in anathemas as freely as the Church of Rome.

Sober and stern the congregation looked, fitting descendants of the rude old Covenanters, who counted their lives as nothing compared with the faith they loved. I joined in the singing with a "good courage," remembering how the forefathers of these people had bought their freedom of worship with their blood; yet it was refreshing to be once more in the bright free air with the birds singing joyously overhead, and the glad sunshine glinting amidst the trees and making the flowing river like a pathway of silver adorn the happy fields.—*FILIX-FEMINA*.

VINES PLANTED INSIDE AND OUTSIDE A VINYERY.

I HAVE Vines (six in number), planted outside my cold vinery. Inside is a very good border about 2 feet deep. I have been thinking I could plant a few Vines here to fill up the vacancies between the present Vines. The borders are on lime rock and well drained. Do you think the difference of temperature in the borders would prevent their being grown together?—A YOUNG BEGINNER.

[Not at all. The Vines will not interfere with each other, though those planted inside may come a little earlier. You might plant so as to have all the Vines ultimately inside, with means for the roots to go out, and then if disposed you might cut out the outside ones as those inside filled the house; but planted in both positions the Vines will do well enough.]

BULBS FOR FLOWER GARDEN DECORATION.

(Continued from page 287.)

RANUNCULUS.

THESE are deserving of more extended cultivation. Being symmetrical in form, brilliant in colour, offering almost every hue found in flowers, and the petals converging to the exquisite moulding of the florist's hemispherical outline, the Ranunculus is unequalled by any of our much-vaunted bedding plants, and worthy of every care. If we wanted a proof that Ranunculus are something more than common, it is the attention demanded for their cultivation—not that they are difficult to grow, but they require something more than ordinary care.

The essentials to success are—first, a free, rich, deep soil; second, an open situation, but sheltered from cold cutting winds; third, though delighting in a moist soil, the Ranunculus is very impatient of those which are cold and un-drained; fourth, not to bury the roots too deeply in the soil, 1 to 1½ inch being sufficient in heavy ground, and 2 inches in light soils; fifth, copious supplies of water when the foliage is advancing and the bloom-buds or flower-knots forming, also when in flower; sixth, slight protection from frost.

The ground in which Ranunculus are to be planted should be dug deeply, 2 feet is not too deep, and at least 3 inches thick of well-rotted manure should be worked into the soil. If the ground is of a light nature cow or sheep dung, because cool, is to be preferred. If the soil where the bed is to be formed is not sufficiently deep, the under-stratum must be taken out to the above depth, and some good, sound, turf-loam put in its place, working the manure in along with the loam to a depth of 20 inches, and on this is laid 4 inches deep of soil in which the bulbs or roots are to be placed.

If the soil is of a very unsuitable character, the beds may be taken out to the depth of 2 feet, and filled up with a compost of hazelly turf-loam, formed of rotted turves a year old, mixed with one-third of well-decayed manure. The materials employed should be well exposed to the action of frost and air for some time, especially if the soil is heavy. In that case the bed will be prepared in autumn, and left rough, so that frost and exposure may do the work of pulverisation.

In soils of a not very wet nature it is preferable to plant in the autumn, though February and March are the usual periods. Autumn planting, however, is preferable on light soils, and not the less on account of the blooming being earlier, and I therefore plant in the beginning of November. On heavy, very damp soils, however, I have occasionally planted in February, but quite as much because the soil was not in a fit state for planting in autumn, as through any fears entertained as to the plants not doing well over winter. In fact, I find more deaths from spring than from autumn planting. The secret in growing Ranunculus is to plant them at such a time that their fibres may penetrate to a sufficient depth to be proof against the drought of spring, if not there will be a failure in the bloom, many not showing a single flower, or if they do they will not come to perfection, the blooms being small, ill-formed, and of short duration. If only the ground be drained effectually, I have no hesitation in saying that they will bloom earlier, quite

as well, and often better, if planted from November 1st to December 15th, as when planted in February or March.

I would recommend planting the Turban Ranunculus in November, and the Persian, too, if the soil be free of stagnant water, and not later than the first week in December, in drills 6 inches apart, and 2½ inches deep, placing the tubers with their claws downwards, firmly pressing them into the ground, and then covering with 2 inches of soil, but if the latter is wet an inch of sand should be put on first, and then the proper thickness of soil. A little before, or by Christmas, cover the bed with an inch of leaf mould about half decomposed, and during frost carefully look after the beds, pressing in gently with the fingers any roots that may be thrown up to the surface. Some cover the beds with a layer of protecting materials, as tan, litter, &c.; I have never found it necessary, and if put on at all, it should be removed before the foliage appears, otherwise it will in all probability prove their ruin. On the other hand, the inch of partly decomposed leaves is almost reduced to nothing by spring, and after acting in winter as a protection will serve in spring to retain moisture, and prevent the surface cracking.

In April and May, the Ranunculus owing to forming its roots near the surface is unable to withstand dryness of the soil: hence it is necessary to water twice a-week, or more or less frequently according to circumstances, a good bloom being dependant on maintaining a uniform degree of moisture in the soil in dry periods. After the flower-buds appear, and whilst in bloom, water between the rows every other day; but when the flowers fade discontinue watering; after the foliage turns yellow take up, dry, and store in a cool, dry place. In watering give a thorough soaking, surface waterings being worse than useless, for by keeping the surface moist under a broiling sun evaporation is excessive, and the temperature lessened, which cannot fail to weaken the plants. It is the fibres that want the moisture, and to reach these it must be given copiously. Dribblings are of no use. Cold, dry air is very injurious to the Ranunculus.

Of Turban Ranunculus, the best for grouping are—Romano, scarlet; Turban d'Or, scarlet and gold; Seraphique, yellow; Hercules, white; Souci Doré, spotted; Grandiflora, crimson; Merveilleuse, yellow; and Turban Noir, maroon.

Of Persian, choose Bella Donna, white, spotted purple; Mont Blanc, white; Nosegay, yellow, brown-spotted, and sweet-scented; Oeil Noir, black; Prince de Galitzin, yellow, brown-spotted; Fireball, bright red; and Commodore Napier, yellow, brown-edged.

ANEMONES.

Elegant in foliage, and brilliant in the varied hues of their flowers, these are adapted for producing splendid groups or masses in the flower garden. They delight in an open soil and situation, but will thrive in all soils free of stagnant water. The tubers intended to furnish an early bloom should be planted in October, the ground being previously dug, and a liberal dressing of leaf mould or thoroughly decomposed manure worked in. Plant if possible during dry weather, about 2 inches deep, and from 6 to 9 inches apart, gently pressing them, for the roots are fragile; and use a little care in placing the right end uppermost.

In January go over the beds, and after stopping up with dry soil all holes made by the foliage pushing through, or worms, place a couple of inches of half-decayed leaves over the beds, between the foliage, which will act as a protection to the crowns and also to the young foliage springing therefrom.

There is a difference as to the time of planting. Some prefer January to October, but I have found October the best time for planting to exhibit them in bloom in spring, so that they may make way for bedding plants at a later period; whereas, if they are planted in January or February the blooming is not past until far on in July, and it is then late for planting bedding plants. I therefore advise their being planted in October or at latest by the beginning of December. I do not say I would adopt this treatment with a choice collection; but, nevertheless, I think that Anemones do not like too long a period of rest, but rather the contrary, it being better to take up rather early to prevent that tendency to commence growth immediately after maturity. Nature is in favour of planting the Anemone in October, as that is the time when her influences are at work on the

Anemone root. I have had splendid beds without taking up the roots at all, by simply removing the decayed foliage and giving an annual dressing of partially decayed leaves in December. This treatment, however, will not do for beds, it being necessary to remove the tubers; and that should be done when the foliage turns yellow, drying and storing them away in a cool dry place until October, when they are to be planted.

Of double Anemones, the best for grouping are Lord Nelson, violet blue; Harold, purple blue; Prince Albert, deep violet; Preciosa, red; Richelieu, scarlet; Superbe (Scarlet Superb), scarlet; L'Eclair, scarlet, the best scarlet; Rose Mignonne, deep rose; Victoria Regina, velvety red; Hortensis, red; Josephine, scarlet; and L'Ornement de la Nature, blue.

Of single, the best is the Scarlet sometimes called Brilliant, and brilliant it is; in addition to which there are mixed colours which no one dare name for fear of being laughed at, and yet they make a great show in spring and early summer.

The blue Wood Anemone (*Anemone apennina*), is like the Wood Anemone, but the flowers are larger—about the size of a crown-piece, of a brilliant sky blue, and the foliage is even more handsome than that of the commoner species. Being a sheet of bloom in April, no plant will command more general admiration, and it will grow anywhere—either in the parterre, park, or grove, but calcareous soil is best. It should be planted at latest by the middle of October. A fitting companion for it is *Anemone hortensis*, or Star Anemone, from the mountains of Southern Europe, and perfectly hardy. The flowers are $1\frac{1}{2}$ inch across, of a ruby-scarlet or purple, and produced in April and May. Seedling plants of these vary much in colour, especially those of *A. apennina*, they being purple in different shades, and white.

A. pulsatilla, so fine in chalky pastures, with its violet flowers, must find its way into every garden; and so ought the yellowish Portuguese species, *A. palmata*. *A. fulgens*, a shining variety of the Peacock's-eye (*A. pavonina*), with the species and the double variety of the Wood Anemone (*A. nemorosa*), also the Garland, both single and double, (*A. coronaria*), from the Levant, must have a place provided for them in some shrubbery-border, which will be all the more frequently visited if gay with a few flowers.

IRIS.

Beautiful in its way, but not so much in beds. The English and Spanish grow well in the open ground in any light rich soil, flowering in June. They should be planted in the end of September or beginning of October in patches of six or more, and about 3 inches deep. The Spanish Iris blooms the earliest, followed closely by the English, which are larger.

IXIA, SPARAXIS, TRITONIA, AND BABIANA.

These are somewhat tender, the difference between hardy and not being due to the depth the roots are planted at. The best situation is a greenhouse border or south border, and the soil should be of a light sandy nature. If it is composed of sandy loam, leaf mould, and sandy peat in equal parts it could not be better. They should be planted from 4 to 6 inches deep, and must be protected by a covering of dry leaves when severe weather sets in, placing a little soil thereon to prevent the leaves being blown about by the wind, and removing it in spring. Grown in this way they bloom much better than in pots, and continue to bloom from May to August. The proper time of planting is October. They should not be moved except for the purpose of increase, as dryness of the root otherwise than in dry soil is more injurious than beneficial.

ALSTREMERIA.

Once grown in hothouses, but now found quite hardy when planted at a suitable depth. *A. chilensis* is suitable for grouping, attaining a height of from 2 to 3 feet, producing numerous racemes of elegantly shaded orange red, yellow, or rose flowers, diversified by lines on a lighter ground. *A. aurea*, orange red; *A. haemantha*, bright flamed red; and *A. psittacina*, red and green, form excellent groups in borders; whilst the smaller kinds, as *A. tricolor* and *A. pelegrina*, are rather more tender, yet form interesting groups when planted in sheltered borders, and do not attain a

height of more than 18 inches. The Alstroemerias retain their beauty as cut flowers in water longer than many plants, and I forget now whether they or the Gladiolus retained it the longer. They like a free rich soil, but will thrive in any good ground, only the subsoil must be well drained. They should be planted from 6 to 9 inches deep, with the bud-like crown uppermost. Once planted they are no further trouble, and it is not uncommon for them to seed and increase at a rapid rate. *A. acutifolia* is a climbing plant, a frame perennial as hardy as any of the others; and *A. argentea vittata* has beautiful variegated foliage, the best in the lot being a hybrid, *A. Ehrembaultii*, which is white-spotted, *A. versicolor* following closely with yellow-spotted flowers. Alstroemerias, however, bloom in August and onwards; and it was not those that I intended writing about on the present occasion.—G. ABBEY.

THE ROYAL HORTICULTURAL SOCIETY'S SHOW.—OCTOBER 19TH, 20TH, AND 21ST.

The objects in which competition was invited on this occasion were fruit and vegetables; and of the former there was a very good display, notwithstanding that no prizes were offered, certificates bearing a money value in proportion to their class and the amount of payments for admission being substituted. The receipts, however, must have been very small, at any rate the first day, for, though the weather was remarkably fine, the visitors not being either Fellows of the Society or exhibitors were few; nor could many be expected when the fashionable world is out of town.

The Grapes and dessert Apples and Pears were ranged on two tables in the conservatory, in one of which Messrs. Lane's pot Vines formed an appropriate centre, whilst the kitchen fruit, roots, and vegetables were placed in the arcade.

PINES.—Only four were shown. A Queen from Mr. Mobbs, gardener to W. B. Tyringham, Esq., Newport Pagnell, had a second-class certificate; and a large and fine Cayenne from Mr. T. Ingram, gardener to Her Majesty at Frogmore, was first, and a Black Jamaica of 6 lbs. 9 ozs., but not in good condition, second in the Any variety class.

GRAPES.—Numerous and excellent bunches were shown both of Black and White kinds. In the latter three bunches of Muscat of Alexandria from Mr. Meads, gardener to Raikes Currie, Esq., Farnborough, were the finest we have seen this season, being large and compact in bunch, large in berry, and beautifully ripened—very different from Muscats as usually seen earlier in the season. The three bunches weighed 11 lbs. 13 ozs. Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading, was second with excellent bunches of the same kind; and Mr. Pottle third with large bunches.

In Black Grapes Messrs. Lane, Berkhamstead, were first with Muscat Hamburgh, very large and well ripened; and second-class certificates were awarded to Mr. Meads for the same kind, weighing, the three bunches, 8 lbs. 3 ozs.; and to Mr. Potts, gardener to Mark Phillips, Esq., Stratford-on-Avon, for Barbarossa, 12 $\frac{1}{2}$ lbs. Three bunches of Black Hamburgh from Mr. Meads, weighing 8 lbs. 11 ozs., large in berry but not highly coloured, received a third-class certificate.

From Messrs. Lane came a fine collection of Grapes, including handsome well-ripened bunches, the berries being also large, of Esperine, Lady Downes', Muscat Hamburgh, Black Hamburgh, Dutch Hamburgh, Bowood Muscat, Golden Hamburgh, and Buckland Sweetwater. This collection added much to the interest of the Show, and well deserved the first-class certificate which was awarded to it; and Messrs. Lane received a similar distinction for the fine collection of Vines, Pears, and Oranges in pots, the former loaded with excellent bunches. Still more interesting was the collection of Grapes grown in the conservatory at Chiswick, and consisting of thirty varieties. Among them were two bunches of Barbarossa, the one a very large bunch weighing 6 lbs. 13 ozs., produced by a Vine on its own roots; and the other borne by a Vine grafted on the Black Hamburgh, which though only weighing 3 lbs. 13 ozs., was very compact and handsome, more regular in the size of the berries, and much better coloured. The two Vines were grown under precisely the same circumstances, and the

difference in their respective productions can therefore only be attributed to the influence of the stock upon the graft. The other Black Grapes were also well represented in Frankenthal and other Hamburg kinds, Muscat Hamburg, Lady Downes', Oldaker's West's St. Peter's, Burchardt's Prince (another first-rate late kind), Black Monukka (which is seedless), Muscat Noir de Jura, Siderites Smyrna, Black Prince, Black Morocco, Esperione, and Morocco Prince. Of White kinds there were Canon Hall, Muscat of Alexandria (well-coloured), Raisin de Calabre (a good late-hanging kind), Blussard Blanc, Golden Hamburg, Royal Muscadine, White Nice, White Frontignan, Royal Muscadine, and Reeves' Muscadine. Of Reds there were only three—viz., Ahbee, pale yellow, with a higher tinge of rose than usual, very beautiful but not very good; Chasselas de Falloux, purplish red, and Tokay des Jardins. Two excellent bunches with good-sized berries cut from the large Vine at Cumberland Lodge, and exhibited by Mr. Ingram, completed the list of notabilities in the Grape classes.

APPLES, both for dessert and kitchen use, were well and numerously shown, but owing to the peculiar character of the season many of the varieties of these, as well as of Pears, were much out of character. For six dishes of dessert Apples, Mr. Ford, gardener to W. E. Hubbard, Esq., Horsham, was first with Cornish Gilliflower, which is known to be at once one of the best and in general one of the ugliest of Apples, but in this case large and well coloured; Adams's Pearmain very fine, Red Pearmain, Scarlet Pearmain, Blenheim and Ribston Pippins, all of which were large and well coloured. Messrs. G. & J. Lane, St. Mary's Cray, and Mr. T. Ingram were second, the former with excellent examples of Ribston and Blenheim Pippins, Bull's Golden Reinette, Cornish Gilliflower, Summer Nonpareil, and King of the Pippins; the latter with Cox's Orange Pippin, Court-Pendu-Plat very highly coloured, Scarlet Nonpareil, Fearn's Pippin, and two seedlings. One of them called Ingram's Frogmore Nonpareil is stated to be an excellent long-keeping Apple, in use from October to March; in shape it is roundish, rather flattened; in colour greenish yellow, with russet markings. The other, Gipsy King, is much more attractive in appearance, resembling Court-Pendu-Plat in size and colour, and having an eye like the Blenheim. It has, we are informed, a firm yellow flesh, and will keep till June. Mr. Buster, Goring, near Worthing, was third.

In three dishes Mr. Ford was first with remarkably large and fine fruit of King of the Pippins, Golden Reinette (?), and Blenheim Pippin; Mr. Hall, gardener to Capt. Tyrrell, R.N., Ealing, second with Blenheim and Cox's Orange, both very fine, and Ribston Pippin. Gravestone, from Mr. Lee, Clevedon, was large and fine; and Fearn's Pippin, from Mr. Kaille, large and very highly coloured.

Kitchen Apples, though not generally so large as we have seen them, were large for the season. Mr. Scrymger, Reading, stood first with Emperor Alexander, splendid, Blenheim and Yorkshire Greening, both very large and fine. Next came Mr. Lee, gardener to Viscount Combermere, Whitchurch, with Mère de Ménage, of a fine red all over, the six weighing 6 lbs. 10 ozs., Blenheim, and Flower of Kent; and Messrs. Lane, St. Mary's Cray, with Waltham Abbey Seedling, Blenheim, and Gloria Mundi. Third-class certificates were awarded to Messrs. Moffat and Sayers.

In addition to several collections of Apples for competition from Messrs. Potts, Bentley, Drewett, Beasley, Hall, Mobbs, Tivey, and others, there was a rich and varied display of 122 sorts from the Society's Garden at Chiswick.

PEARS were likewise numerously shown. The best six dishes were those from Mr. T. Ingram, gardener to Her Majesty, consisting of Beurré Diel, Beurré Clairgeau highly coloured, Glou Morceau, Van Mons Léon le Clerc, and Chau montel, the whole of which were very fine; and British Queen, a richly-flavoured cinnamon-coloured Pear of his own raising, and which has been already described in these pages as being of first-rate excellence. Mr. Scrymger was second with Glou Morceau, Marie Louise, Beurré Diel, Beurré Rance, Vicar of Winkfield, and Beurré Bosc; and Mr. A. Ingram, also of Reading, third with the first three kinds, Duchesse d'Angoulême, Van Mons Léon le Clerc, and Beurré Bosc.

In three dishes Mr. Sage, gardener to Earl Brownlow, Ashridge, was first with Beurré Rance, Glou Morceau, and Duchesse d'Angoulême; Mr. Ford second with Glou Mor-

ceau, Thompson's, and Marie Louise; Mr. Lee and Mr. Willcocks third.

Kitchen Pears chiefly consisted of Uvedale's St. Germain, Catillac, and Beurré Rance, but none of them were remarkable for size. The first-prize lot from Mr. Bentley, gardener to Lord St. Leonards, Thames Ditton, consisted of the last two and Beurré Langlier. A collection of seventy-two dishes of Pears, comprising many interesting kinds, came from the Chiswick Gardens.

MISCELLANEOUS.—From Mr. Ingram, Frogmore, and Mr. Ward, Headington Hill, came excellent Salway Peaches, the former taking the first place; and of Plums, Coe's Golden Drop, and Ickworth Impératrice, were shown by Mr. Mobbs, and Mr. Sayers. Raby Castle Currants from Mr. Tivey, the Hyde, St. Albans, were remarkably fine, even at this late season; and White Dutch from the same, and Mr. Ford, were also very good. Mr. Williams, gardener to the Hon. Mrs. Ives, showed good Morello Cherries, Dutch Medlars, and a basket of well-grown Citrons; Mr. Potts, a fine basket of Oranges and good Morellos; Mr. A. Ingram, Eugenia Ugni; Mr. Mobbs, Black Prince Strawberry, very good for the second crop; Mr. Ford, Quinces; and Mr. Whiting, the Deepdene, Meredith's Hybrid Melon. For the above objects numerous certificates were awarded, for which we must refer to the prize list.

VEGETABLES AND ROOTS.—The exhibition of these was meagre, with the exception of the Potatoes, of which a collection of fifty-six was sent from the Society's Garden at Chiswick, and to these we may take occasion to refer hereafter. The only exhibitor of Kidney Potatoes was Mr. A. Moffatt, who had Imperial, an excellent kind, Royal Ashleaf, Pink Fluke, Flesh-skin Kidney, Prince of Wales, and Lemon Kidney, a large and clean tuber, all of which were free from disease, and otherwise excellent. The same may be said of the Round kinds exhibited by Mr. Moffat, among which were Daintree's, very sound and clean. Fortyfolds and Regents were shown in good condition by Mr. Ford; and a seedling called Hands' Freedom, said to be very good and productive, by Mr. Hands, Newcastle-on-Tyne; Chardon, a large knobby continental variety, stated to be very productive and useful for feeding cattle, by Mr. Veitch, Chelsea; and Lemon Kidneys, large and fine, by Mr. Bentley. Good Onions, Carrots, Beet, Incomparable Celery, Scorzonera, and Walcheren Broccoli, beautifully white and close in the curl, were shown by Mr. Whiting; White Belgian Carrots, Batavian and Curled Endive, by Mr. Veitch; excellent Salsafy, Scorzonera, Beet, and Turnips, by Mr. Drewett; Mushrooms, Beet, a Mammoth Gourd, weighing 123 lbs., and Dwarf Curled Savoys, by Mr. Young, Highgate; and White Stone Turnips, Endive, Early York Cabbages, and Walcheren Broccoli, by Mr. Ford. Tomatoes came from Mr. Morris, and Mr. Salter, those from the latter being called the Cherry kind, but in reality Pear-shaped; Aubergines from Mr. Potts; excellent Endive from Mr. Masters; Mushrooms from Mr. Rogerson; Peas from Mr. Tivey; and Brussels Sprouts, closely set with large sprouts, from Mr. Scrymger. For the certificates awarded, we must again refer our readers to the official list.

THE ABERDEEN STRAWBERRY TRADE.—As most people who are acquainted with our city know, the Aberdeen market-gardeners have for long been highly successful cultivators of the Strawberry. In respect to bulk and flavour the varieties of this excellent fruit grown by them will hardly be exceeded. Few people, however, we believe, have any very tangible notions of the actual extent to which the cultivation of the Strawberry has grown. We usually think of Strawberries in pints or quarts, not in hundredweights and tons; yet Strawberries by the ton have become an actual item of export, and during the present season the quantity brought into the market and sent southward, chiefly to London, to be manufactured into preserves, amounted to about 35 tons. This is independent of considerable quantities used at home for the manufacture of preserves on the wholesale principle, and for ordinary domestic use, &c., which must have brought up the total quantity to something like 50 tons; and if we take into account that a ton of Strawberries is worth from £25 to £30 (probably only smaller

quantities reaching the latter rate), it will be seen that this has become no unimportant branch of market-gardening. It is a branch, moreover, that promises to extend. It is only a few years since Strawberries began to be exported southward at all; but the demand is, we understand, very keen, and even beyond the supply, and contracts to the extent of 30 tons have been already entered into for next season, while some of the principal growers are considerably extending the breadth they have under cultivation. Of the Strawberries preserved by wholesale "curers" no inconsiderable part are exported to the Continent, and some even to India.—(Aberdeen Free Press.)

ZONALE GERANIUMS AT LINTON PARK.

(Continued from page 306.)

CLASS 4.—*Geraniums with flowers of a cherry, ruby, or salmon colour; foliage plain or horseshoe-marked.*

Rubens.—This old favourite is still deserving of cultivation, as its habit of growth, free blooming, and general adaptability to most situations give it a place in most collections. It is slightly horseshoe-marked, the foliage at the same time being downy.

Carulea.—Foliage, medium horseshoe marking; habit rather upright; flower-truss very good and well formed. It possesses a brightness about it of which most of the others in its class are deficient, and whether in a flower-bed or a pot it may be pronounced one of the best Geraniums grown.

Countess.—Somewhat like the last, but the individual flowers are less perfectly formed, and less bright; in habit of growth and freedom of flowering there is little to wish for in it.

Madame l'Abbe.—Strong grower; slight horseshoe marking; flower approaching somewhat to a rose. With me, however, it flowered late, but it may have been prevented doing so earlier from other causes than its own disinclination to flower.

Hector.—Habit good; dark horseshoe marking; flowers produced freely, of a pretty rosy salmon colour. Not being sufficiently tried I cannot say more than that it promises well.

Rose Perfection.—This scarcely belongs to this class, its flower being a sort of happy medium between rose and pink. It is one of the very strongest of all growers, and in the past season bloomed remarkably well. The habit is upright, and the foliage only faintly marked with the horseshoe.

Conqueror of Europe.—Foliage with a darkly-marked horseshoe; flowers a sort of cherry salmon, of good form and habit. The plant is promising, but receiving it late in the season I cannot speak positively as to its merits.

Ratazzi.—Nosegay. Slightly marked with a horseshoe. Like most of its class it flowers freely, and will no doubt answer well as a bedder.

CLASS 5.—*Flowers scarlet; foliage either plain or but slightly marked with the horseshoe.*

Punch.—Foliage slightly downy; habit strong and erect rather than spreading; flower-spikes well elevated above the foliage. A well-known variety, much grown and appreciated; it is much taller than Tom Thumb and others of that class, although much less than the next variety.

Mrs. Mayler.—A very strong grower, with immense trusses of bloom on long and stout flower-stems. It is of the same class as used formerly to be known as the Giant, Smith's Emperor, Sol, and I believe other names. It is better adapted for growing against a wall than for a bed, although a few plants of this surrounded by dwarfer ones answer very well, its very strong stems rushing up to a great height when they are protected.

Sutton's Perfection, called also, I believe, Attraction, is a somewhat strong grower, though much less so than those previously mentioned. It is one of the very best bloomers, and the trusses are large and fine; but with me this past season it was late—a fault I never before had to find with it, and for which I cannot account. Most growers admire it, and it is equally at home in a pot under glass.

Tom Thumb.—Notwithstanding all that has been said in favour of others, this is still unquestionably the most popular Geranium of the day. I am, however, convinced that there are more varieties than one cultivated under the name of

Tom Thumb, and where the spurious or inferior one exists it is quite possible other kinds may excel it. The foliage of Tom Thumb approaches nearly to what I have on more than one occasion stated to be what I want in a bedding Geranium—*i.e.*, a clear bright green, free from horseshoe markings, and also from that downiness which gives a dull colour to the foliage, and which in some respects detracts from the merit of Christine and other varieties.

Royal Dwarf.—Somewhat like the last, but a less abundant bloomer, and instead of being dwarfer than Tom Thumb it is a more robust grower. It is, however, not by any means of a gross habit, but blooms and flowers well, and deserves a place with those who delight in a multitude of names.

Little David.—Dwarfer than Tom Thumb, very free bloomer, and well adapted for vases. It is of the same habit as Tom Thumb, and, like it, deserving of better treatment than some of the shy bloomers. Little David deserves a place in the most limited collection.

Crystal Palace Scarlet.—This, which I had also under the name of Trentham Scarlet, is of the Tom Thumb class, the foliage being a bright green; perhaps, however, the plant is a little more upright-growing, but this is a questionable qualification; and some growers of this variety insist that it is identical with what they have grown for years as Tom Thumb. The difference here is not sufficiently marked for me to say with certainty that it is distinct from that well-known variety, which I have had nearly twenty years. I would, however, advise all growers to try Crystal Palace Scarlet, and ascertain whether it is really distinct from and an improvement on Tom Thumb.

CLASS 6.—*Flowers scarlet; foliage more or less marked with the horseshoe.*

Queen of England.—Marking very dark; strong grower, somewhat upright; fine truss. Better for pots than for bedding-out, excepting for the centre of beds, or where a tall upright plant is wanted.

Compactum.—Marking very dark. This old kind seems to be eclipsed by others of its class, therefore I cannot recommend it, as I intend discontinuing its use after the present year.

Marvel.—Horseshoe marking only slightly shown; habit of plant good; flowers pale scarlet; petals large and fine. Standing the sun tolerably well, and being of a distinct tint from the bulk of our Scarlets, it promises to be a favourite.

Scarlet Globe.—Foliage slightly marked with horseshoe; habit strong and pretty good; flowers with a white eye, but in general they are small for so vigorous a plant, and not being remarkable as a pot plant, it may be discarded.

Blazer.—This is one of the Zonale class, having the markings composed of two or more colours, a class at one time expected to become fashionable; but having failed to produce a good effect in the flower garden, and those hitherto presented to us being somewhat leggy and ungainly for pot culture, they have latterly ceased to be noticed. Another feature they present seems also to be no particular qualification, the flower-stem is often white and semi-transparent. The flowers of this variety have a white eye, and as a scarlet are not without merit; but the irregular growth of the plant disqualifies it for all symmetrical work in flower-beds.

British Flag.—Fellow to the last-named, perhaps a little more robust, and the trusses of bloom a shade darker.

Adonis.—Dark horseshoe marking; flowers pretty good, light scarlet, somewhat like Marvel; habit good. It promises well, but not having many plants I cannot speak with certainty as to its merits.

Vivid.—I am somewhat uncertain whether the variety which we have under this name is true, it having a slight horseshoe marking. The habit is strong and somewhat upright; flowers in a large truss, bright, fine, and good.

Prince Imperial.—Of more dwarf habit than most of this class, and consequently better adapted both for beds and potting; flower-truss good, bright scarlet. One of the best of this section.

Stella.—This popular variety is more of a crimson than a scarlet, but is nevertheless often planted as one of the latter, and as such may be classed here. Of its merits it is needless to speak, as it shone pre-eminent in most of the public gardens around London, when it was put in competition

with other Geraniums; to those not acquainted with it I may say it is a sort of half Nosegay; habit spreading; foliage nearly plain green; flowers in fine trusses, and most abundantly. It is one of the memorials our late lamented fellow labourer Mr. Beaton bequeathed to the gardening world. Stella is very good as a potted plant, but thrives best when planted in a mass in a flower-bed.

Cybister.—I fear this is a still further departure from the scarlet, but I hardly know under what section to class it. I must in the first instance, however, say that my acquaintance with it is limited. Not having grown it until the present year, and that but sparingly, I cannot speak confidently on its merits, but may say it is more of the Nosegay breed than the last, the flowers being also more crimson. Many growers, however, speak well of it.

CLASS 7.—Flowers rose colour.

Trentham Rose.—This popular variety needs no comment, the plant being all that can be required in habit, and the flowers individually are as good as those of the majority of recently introduced varieties, and better than many of them; but it must be acknowledged that, viewed at a distance, the flowers have not the attractive colouring of Stella and some of the Scarlets—they are more for effect close to the eye. In habit the plant is spreading, and the foliage scarcely shows any horseshoe marking.

Paul l'Abbé.—A more robust grower than the last, with foliage distinctly marked with horseshoe. Flower-truss very large, and plant more upright-growing. For the centre of a bed this is a desirable variety, while its immense trusses of bloom are of themselves sources of much attraction.

Beauty of Mildoise.—This so much resembles Trentham Rose, that I am far from certain that they are not synonymous. More need not therefore be said about it.

Cerise Unique.—Having all but thrown this old variety away, I only mention its name as one of this class having a more upright growth, foliage marked with horseshoe in two colours, and the flower-stem white.

CLASS 8.—Flowers purple, or approaching that colour.

Magenta.—Slightly horseshoe-marked; strong grower, but spreading; half Nosegay; truss large and fine, and of the lovely colour implied by its name. Next to Stella, it is the most telling Geranium that can be planted, being of a colour hitherto not approached by any Geranium.

Imperial Crimson.—Nosegay; foliage small and plain green; habit dwarf; flowers good purple, and very abundant. A good plant for edgings or for a single line in a ribbon, the compactness of its habit fitting it admirably for that purpose.

Woodwardiana.—I am somewhat doubtful whether this be the correct name: if so, it is somewhat like the last in colour of flower, but more robust in growth. It is also a Nosegay, not altered by hybridising with the broader-petaled class.

Lucidum.—This old variety of the Nosegay class, the first I was acquainted with, excepting Harkaway, seems to degenerate, or other kinds have surpassed it in beauty and general qualifications. I shall discard it.

Purple Nosegay.—This once-popular variety becomes so leggy and bare of foliage that it no longer deserves cultivation, and compared with Magenta it is worthless.

Lord Palmerston.—Foliage nearly plain; flowers partaking of the Nosegay class, more of a crimson than purple; habit good and promising. Not having seen much of it, I must leave its properties to be commented on by others. It promises well.—J. ROBSON.

CULTIVATION OF SOME RARE WILD FLOWERS.

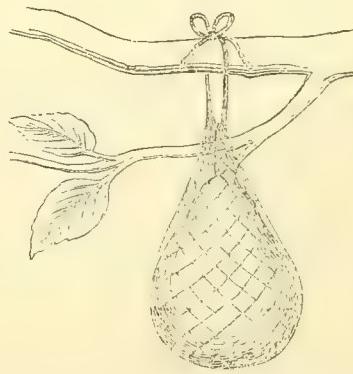

PRIMULA FARINOSA.

TOURISTS who visit the upper parts of Aire and Wharfedales during the months of May and June, are often charmed with the beautiful flowers of *Primula farinosa* (Bird's-eye Primrose), and bring back plants which they have collected in the moorland pastures. These are planted in the gardens at home, where they grow, and for a time all is well. If we

afterwards inquire after them we are told that the roots are dead and thrown away. Not so, the leaves were dead, but the roots were alive, though dormant, peeping out of the soil like a little bud, ready for growth early in spring to flower and please the collector who gathered them, and to serve as a memento of a visit to a wild but charming district.

This flower is one of my favourites, and was some years since gathered for me by a friend in the Craven district, where it grows very plentifully, and Baines in his "Flora of Yorkshire," informs us that it may be found varying from the purest white flowers to the deepest crimson. It is of very easy culture, growing in almost any kind of soil, and seems to do best in that collected from the sides of roads repaired with dross or slag from the iron works in our neighbourhood; but it will grow and do well in common garden soil. The best time to increase it is in spring as soon as the plants commence growing; if we then take up a root we find it composed of a number of little buds clustering round the family hearth. These are easily divided with the fingers, taking care that a small root is with every bud, and the small buds will flower the same year. If allowed to flower, and then divided, the roots are tough, and do not easily part, and few plants are obtained; these, if the weather be dry, seldom do well.—RUSTIC ROBIN.

PREVENTING THE FALL OF SPECIMEN PEARS.

I HAVE sent you a little box of Pears merely to show you an idea which struck me in the summer, as answering to keep large Pears from being blown down by the wind. I have before had a good many King Edward's Pears, but they were nearly always blown down before they were much more than half grown. Tying them does not answer, and I thought small net bags would do, and they have answered admirably. The bag should fit moderately close, as the Pear is not suspended by the bag so well if the bag is too large. I tie the string to the same branch unless the fruit is on the end of it, and then I tie it to an adjoining branch, so that the weight of the Pear is in the bag.—GEORGE LEE, Clevedon.

TODMORDEN BOTANICAL SOCIETY.

MEETING OCTOBER 3RD.

THE President in the chair. The President exhibited fronds of a most beautifully-crested form of *Athyrium Filix-femina*, lately gathered by him near Hapton. Mr. J. Sim, of Perth, sent a specimen of *Rosa alpina*, L., recently discovered on Kinnoul Hill, near Perth, by Dr. White, jun., of that city. This Rose is said to be new to Britain, and Dr. White may be congratulated on making so important an addition to our flora. Mr. Aitkin, of Bacup, exhibited specimens of *Alisma natans*, from the Vale of Llangollen. Mr. Halstead, of Bacup, a most indefatigable Fern-hunter, brought various interesting forms of *Blechnum spicant*, recently collected by him in the neighbourhood of Rossendale: one of these forms the President pronounced to be new. Mr. Halstead also exhibited fronds of *Scolopendrium*

vulgare crista-galli, a very fine variety, lately gathered in Sheddin Clough, and a curious dwarf *Polystichum* from the same prolific locality.

The Society's late excursion to the Isle of Man, of which the Secretary gave an interesting outline, was not nearly so well attended as we had been led to anticipate; the lateness of the season, and the miserably wet weather combined having apparently damped the ardour of most of the intending excursionists.

List of Plants Gathered on the Isle of Man Excursion:—

PHÆNOGAMS.—*Arenaria maritima*, *Anagallis tenella*, *Brassica monensis*, *Crambe maritima*, *Cochlearia danica*, *Hypericum androsaemum*, *Draba hirta*, *Saponaria officinalis*, *Lepidium Smithii*, *Pinguicula lusitanica* (very plentiful at the bottom of Growdale), *Pyrethrum maritimum*, *Conium maculatum*, &c.

CRYPTOGAMS.—*Osmunda regalis* very abundant and fine, *Adiantum capillus-Veneris* (in great abundance on rocks and in caves close to the sea to the north of Glen Mea), *Asplenium adiantum-nigrum*, *A. trichomanes*, *A. ruta-muraria*, *Allotropa crispa*, *Blechnum spicant anomalam*, *B. spicant multifurcatum*, *Lastrea Filix-mas producta*, *Polystichum angulare paleaceum*, *P. angulare triplinatum*, *P. angulare subtripinnatum*, *Polypodium vulgare semilacerum* (very abundant and fine at the waterfall, Glen Mea), &c.

PRESERVING WALNUTS.

REMOVE the husk and wash the nuts thoroughly in clean water. Now throw them into a saline solution made thus—water one gallon, common salt $\frac{1}{2}$ lb., nitre 1 oz. The nuts are not to be kept in the solution longer than is required to put them into it and take them out again. Place them upon a sieve to drain, then wipe them with a rough cloth. Now pack them, where you will, with cocoa-nut refuse, or with broken charcoal. When required for table they should be washed and dried. Walnuts thus treated will rarely become mouldy; nevertheless, like all things of this earth, they ought to be "looked to" now and then, for one rotten Apple will spoil a bushel.

As a general rule cellars are not the places to keep Walnuts, because there are therein always the sporules and germs of mould-forming plants.—SEPTIMUS PIESSE, Chiswick

FOUNTAINS.

"A SUBSCRIBER" wishes to know what kind of fountain would look well in a moderate-sized garden. It is to be placed in the centre, where four gravel walks meet at right angles. One of the walks extends 180 feet long, and the fountain will be about 90 feet from the drawing-room windows. The gravel walks are 8 feet wide, and it is intended for the walk round the fountain to be about 5 feet wide. The fountain, including the basin, must not be more than 11 feet in diameter. Which is thought better, iron or composition of stone? and what height should it be?

[The question of fountains is one chiefly of taste, position, and the supply of water, and the information you give us is too scanty to enable us to advise you as we would wish to do. There is a difference between a mere basin and a fountain. The one is merely a receptacle of water, giving little or no indication as to how the water is to be supplied; a fountain, on the other hand, indicates more or less the outburst of water from a jet, and which presupposes a natural or artificial reservoir of water at a much higher level than the fountain. Such a fountain is always best placed in a valley, because then the surrounding heights will always give the idea of its being natural. A fountain on elevated ground always shows that if that fountain is to play it must be through means of water raised mechanically to a still greater elevation. The command of this water ought to regulate the size of the fountain or basin, and the height which it appears above the ground level. For a fountain 11 feet in diameter of basin, if the basin is 2 feet or 18 inches above the ground level, we think it would be enough; and a raised figure in the centre in the shape of a mermaid or triton, or even several smaller basins, one above the other, the water coming out of the uppermost, or even out of them all, would

look very well. The height above the basin may be from 3 to 10 or more feet, according to the supply of water. Iron, we believe, would be best for such decorative fountains, to be painted and sanded when wet. Perhaps one of the best ways would be to build the tank or basin with brick and cement, and have an iron coping dipping down some 15 inches into the water. Such fountains should either be empty or covered up in winter. The best plan is to empty all the supply piping at any rate. Composition will be apt to trouble you after severe winters. We incline to the iron, but both are good when no water is left to freeze. Even stone will crack if left wholly exposed with water in it in winter. We cannot recommend makers, nor is there need, as there is no lack of them.]

ENTOMOLOGICAL SOCIETY'S MEETING.

THE October meeting of the Entomological Society was held on the 3rd inst., Francis Pascoe, Esq., F.L.S., President, in the chair.

A case of insects of various orders containing many rare species, especially of the genera *Bolboceras*, *Hesperia*, and *Mantis*, collected in India by Lieut. R. C. Beavan, was presented to the Society by that gentleman.

Three minute species of Beetles belonging to the family of the Rove Beetles, *Staphylinidae*, were exhibited by Mr. Sharpe, as new to the British lists, and which had been collected by that gentleman in Scotland.

A box of insects collected on the coast of Brazil, from Rio Janeiro to Monte Video, by Mr. T. Pullinger, R.N., was exhibited by Mr. Ianson.

The President exhibited two remarkable species of Beetles recently received by him from Australia, belonging to the genera *Atractocerey* and *Cyphagogus*.

Mr. Wallace stated that he had captured several species belonging to the former of these two genera during his residence in the Eastern Archipelago, and that they were wood-feeders in their economy.

Mr. Doran exhibited the rare British Moth, *Botys asinalis*, which he had captured during the month of August last near Lyme Regis.

Major F. Parry exhibited a box of insects collected at Gibraltar by one of his sons, also a *Curculio* from Brazil, from the body of which a number of elongated vegetable filaments had been produced, belonging apparently to the genus *Sphaeria*.

Professor Westwood stated that he had illustrated and described several similar examples of these vegetable parasites in an early volume of the Society's "Transactions," and that there appeared to be several very distinct, and probably undescribed, species of fungi which attacked insects preserved in cabinets. One of these is remarkable as being composed of very fine threads of such great tenacity, that in cleaning the insects from the mould the tarsi of the specimens were often pulled off. The subject was very deserving of the attention of microscopic botanists.

A memoir by Mr. Baly, containing descriptions of new exotic species of Plant-feeding Beetles (*Phytophaga*) was read.

Mr. F. Bond stated that he had found that several partridges which he had lately shot, had fed upon the larvae of *Agrotis segetum*, which had this summer and autumn proved so destructive to the root crops throughout the kingdom.

CULTIVATORS OF THE SOIL IN ILLINOIS.

In this prairie State are some of the largest farmers of their own lands in the world, many of their corn fields containing 500 to 1000 acres, where the reaping machine has ample room and verge enough to display its powers. Without this great saver of labour, in a country rife with fever and ague, the crops must otherwise be lost from want of hands in harvest time.

Among the great farmers of the State are Messrs. Jacob Straun, Ike and Jemi Funch (brothers,) and others holding several thousand acres, the landlord and tenant system being unknown. Mr. Straun held about 30,000 acres, almost rivaling Job in the number of his quadrupeds. He used to supply

by contract all the butchers of St. Louis, a city then having 120,000 beef-eaters, the prices being fixed once a-year. Beef falling in price, the butchers thought they should throw up a bad bargain, and refused taking his cattle. Mr. Straun sent his men through the neighbouring district buying up all the fat cattle and selling them at Cincinnati and other towns, or sending them east, so that for a month the citizens of St. Louis were without a roasting joint, when the butchers had to "cave in," or surrender at discretion.

This monarch of quadrupeds riding along and seeing a young lady milking a cow asked for a drink, which the milk Hebe gave him. He then inquired if she knew who he was, to which there was a yes, when he popped the question of marriage, to which another yes was given. Returning the same way a few days after, he called at the farmer's house, where they were at dinner, and not recognising his sweetheart among half a dozen of sisters, he requested the young lady who accepted his offer to stand up, which was done, and they were soon after man and wife.

The Messrs. Funch may at present be the largest farmers in that great State; one brother owning and working 32,000, and the other 17,000 acres of prairie—the former annually selling in Chicago £12,000 worth of cattle and hogs, the produce of his own fields. They were among the first pioneers of the State; one of them on marrying trading a hat with the clergyman performing the service, and getting back a pig in exchange. In these early days the Western farmers were addicted to euker and poker, as well as whiskey drinking, though now very temperate, and on an occasion when one of these gentlemen found his neighbour card-sharpening, he pulled the leg from the table and cracked the cheater's pate. Greater punishment has often been inflicted in the Mississippi steamers on the gamblers by nailing their hands to the table with the bowie knife, which is only withdrawn with the false card.

An amusing incident took place at the American Hotel, Springfield (where President Lincoln practised as an attorney and counsellor at law, with a monster sign-board over his door). Several large farmers, in wet weather, put up at the hotel, turning into the sheets with their mud boots on and discolouring blankets, bed, sheets, and quilt. A short time after they again called, but were refused admittance or lodgings, when they put an advertisement in the papers through the States calling on their brother farmers not to stop at the American; but a counter one was inserted by the landlord, giving his reasons for turning the gentlemen out of doors, and no doubt most of our readers will consider them conclusive. Neither Messrs. Funch nor Straun were on the printed list, but it comprised the names of some of the wealthiest and largest farmers in the West.

Fat salt pork and beans form the chief food of the Western farmers, who might live like princes on the barn-door fowl (if they would only feed them) and prairie chickens (grown) and quail, as well as other game, and fish when in season. Vegetables they never think of, though the prairies would produce them in abundance. As to tea, it is "cisalpine," uninjured by a sea voyage, being chiefly manufactured in Philadelphia and Boston—one-third of that used in the West being "Bogus." In one wholesale house in the western metropolis, where the stock was 2700 chests, over 900 were home-made. The farmers must have tea at 1s. per lb. The country store-keepers must have it at 9d. per lb., to supply the farmers, and the wholesale merchant must have it at 6d. per lb., to give him a fair profit; the Philadelphian or Boston "wooden nutmeg" tea-maker getting 6d. per lb. for drying and colouring leaves.

A SUGGESTED COMPROMISE.

A MEDICAL friend, who has combined the study of natural history with that of surgery for many years, on hearing my bitter complaints of the destruction of the buds of my Gooseberry bushes by the birds in winter and early spring, recommended to me as a certain antidote to sow a few patches of Barley and white Clover in the neighbourhood of the trees. The birds, he says, must have green food at that season of the year; and so long as they can procure the tender blade of the Barley, and their still more favourite leaf of the white Clover, they will not condescend to meddle

with the coarser production of the Gooseberry. The trial will be simple and inexpensive, and is certainly worth making.—T. S.

LATIMERS.

This delightful residence of the Right Hon. Lord Chesham is beautifully situated on a commanding eminence two miles from Chesham, three from Amersham, and six from Rickmansworth, the latter being the nearest place by which at present access can be had by train. By the latter we took our route, and after passing some finely undulated scenery, and the pretty village of Cheneys, and its church with its elevated spire, more than a mile distant from Latimers, we ere long crossed a rustic bridge, attended by a noisy waterfall of the Colne, and, after climbing a steep hill, arrived at the commodious and picturesque cottage of our friend Mr. Donaldson. The more proper entrance, we presume, would have been by the farm at the southern side of the lake, from which a nice approach, after passing over a bridge with a fine view of a deep cascade, winds up to the mansion, the building being as a matter of necessity amid the swells and undulations of this part of the Chiltern Hills. Just opposite the roadway from Mr. Donaldson's premises is a splendid Elm, with a seat placed round its bottom, on which those tired with the ascent may "rest," and thus far "be thankful," the Elm dividing upwards into five large stems, and its main circumference at some 4 feet from the ground being fully 18½ feet. From this position the approach soon forks, one part going westward to the stables and onwards, passing the north side of the kitchen garden, and the other going south-west to the offices and mansion.

The mansion is a noble Elizabethan building, with the carriage entrance on the east side, the flower garden on the west, and a terrace garden of gravel and grass on the south front. Westward of the mansion, and on both sides of the river, the park scenery is continued; and north of the flower garden the principal part of the pleasure grounds are situated, containing many nice specimens of the best young Conifers, Hollies, Yews, &c.

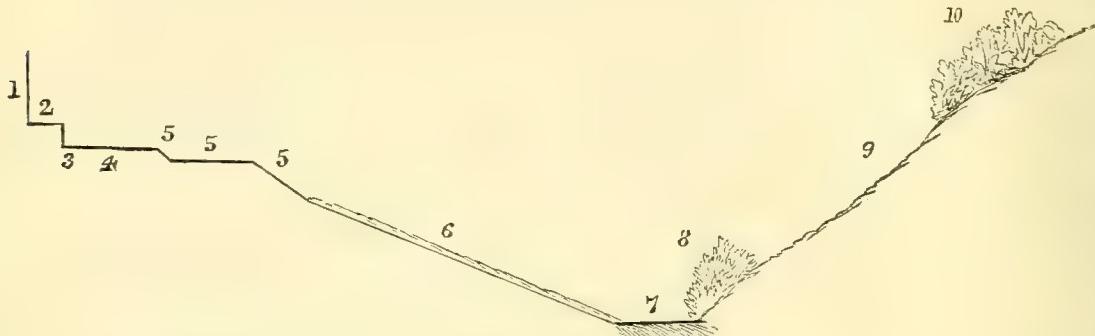

Having satisfied ourselves with the beauty of the east front, and the picturesque outline of shrubs and trees by which the gravel was surrounded, we entered on the south terrace, and the beautiful prospect far more than counterbalanced the trouble of climbing up and descending the undulating hills. We will just for the present leave details, and take you with us, whilst we stand together on the gravel in front of the terrace wall (see section of ground from memory). There, right before you is the beautiful turf with its slopes and levels, and the pasture ground down to the lake almost as fresh and green; the lake itself clear as a mirror, and only needing the dash and the spray of the cascade to be seen to enhance its beauty; the fine trees here fringing its farther bank; the bold sweep of the sheep walk beyond, which could only be more beautiful if more extended, bounded by plantations farther to the south, and forming the sky outline. To the westward the vale, with its undulating banks on each side of the river, opens up broader and wider, and the trees are grouped, and the plantations fringed and curved with rare picturesque effect. Eastward, after the eye has wandered over diversified scenery, it seems to linger on the top of the spire of Cheneys church, the church itself, as well as the village, being concealed by the surrounding woods, and the whole forming a panorama of the beautiful not soon to be forgotten.

Amid all this beauty there was just a trifle that seemed to jar on the unity of the scene, and we feel glad we noticed it, because the explanation was so satisfactory and honourable to all the parties concerned. Just opposite the mansion the boundary of the farther woods (10) stands out almost in a straight line, contrasting unfavourably with the bold massive scenery to the eastward, and the picturesque outlines to the west. This led to our being informed of what otherwise we should never have guessed—that the wood with the straight line, as well as the land up to Cheneys on that side of the river, belonged to the Duke of Bedford; and that though the Duke had let the land to Lord Chesham, and given him full powers to do with the trees as he liked, there might be a little delicacy in meddling even with the young woods. One thing is certain, that the removal of a

few young trees, so as in this one part to take away the stiff outline, would be a great improvement.

When cottagers, as well as squires and noblemen, are apt to quarrel and be very conservative as to their landmarks, it is pleasing to find our highest aristocracy, instead of making these landmarks conspicuous, showing rather their anxiety that their property, if possible, should be made to contribute to the interest and the beauty of the residences of their neighbours. We were here reminded of what, if time and circumstances had permitted, we should have mentioned long ago, the great-heartedness in similar circumstances of the Earl of Derby and Lord Sefton, whose rides and drives so meet and continue on their separate demesnes, that a stranger would have no means of knowing, without being informed, on which nobleman's grounds he was passing.

Though, therefore, part of the scenery to the south-east may not absolutely belong to the proprietors of Latimers, they may well rejoice in and enjoy its beauty. Here we have been reminded of a striking passage in the first volume of "What Will He Do with It," by the great novelist and statesman, Sir Edward Lytton Bulwer Lytton, where alluding to diversity of scenery, "The new villas, or old manor houses on lawny uplands, knitting as it were together England's feudal memories with England's free-born hopes; the old land with its young people; for England is so old, and the English are so young;" and he goes on to tell us how, in their wanderings, "the grey cripple and the bright-haired child often paused and gazed upon the homes and demesnes of owners whose lots were cast in such pleasant places. But there was no grudging envy in their gaze, and therefore,

SECTION OF GROUND IN FRONT OF THE MANSION.

1. Front of mansion.
2. Narrow terrace.
3. Strong terrace wall, continuing westward as far as the flower garden extends.
4. Broad walk extending still farther westward into the pleasure-ground and park.

5. Level and slopes of kept grass.
6. Slope of pasture to the lake.
7. Lake formed by damming up, by means of a cascade, the river Colne.
8. Fine groups of trees on south side of the lake, and mostly concealing farmhouse and buildings.
9. Sheep walls on opposite hill.
10. Picturesque banks of trees, terminating the sky outline.

they could enjoy and possess every banquet of the eye; for at least the beauty of what we see is ours for the moment, on the simple condition that we do not covet the thing that gives our eyes that beauty. As the measureless sky and unnumbered stars are equally granted to king and beggar, and in our wildest ambition we do not sigh for a monopoly of the empyrean, or the fee simple of the planets; so the earth too with all its fenced gardens and embattled walls, all its landmarks of stern property and churlish ownership, is ours too by right of eye. Ours to gaze on the fair possessions with such delight as the gaze can give, grudging to the unseen owner his other, and it may be more troubled rights, as little as we grudge an astral proprietor his acres in Capricorn. Benignant is the law that saith, "*Thou shalt not covet.*" Ah! a grand thing it is for us working men, *this right of eye.*

Coming to the details, we may mention that the upper terrace of grass, marked 2 in the section, seemed narrow for the size of the house. It was level with the top of the wall 3, which is a very substantial affair, and built of square blocks of light stone, alternating with one seemingly of flint or various coloured granite. This gave a variety to the look of the wall, and on the whole we think made it more interesting than if it had been all of one colour, as both of these lozenges contrasted with the red colour of the mansion.

This wall extends as far as the flower garden does. There is no balustrade separating the upper terrace from the lower terrace, but large, massive, sculptured stone vases were set all along at regular distances, and were well filled with Scarlet Geraniums, &c. This answers very well just now, as we do not consider the flower garden quite finished; but when it is, either a low balustrade would be required, or an increase in the number of vases.

Beautiful as the grass terraces looked, still there is an appearance of baldness in the beauty, owing to the south front, with the exception of the vases on the top of the terrace wall, having no shrub or tree to distract the attention from the lawn, lake, &c. We think the baldness would be best remedied by some elegant tubs with Portugal

Laurels being placed along the south side of the walk, the tubs being a mere make-believe for artistic effect, the roots being chiefly in the ground, as Mr. Henderson managed them at Trentham. Irish Yews every 30 feet or so would also have a good effect. Vases with flowers would add richness but do much to neutralise the unity of the scene, as with the exception of these vases on the terrace-wall, we have yet seen no flowers, nothing to distract the mind from the green turf and the picturesque scenery. These nicely-trained Laurels, &c., would add the artistic to the picturesque, the artistic where it should be seen near such an elegant mansion, and that without interfering with the distinct unity of expression in this south front, which the introduction of floral ornaments would be sure to do.

No doubt many of our artists would like to lay down a parterre on the wide space of lawn between the first slope, and no doubt it would look beautiful and be quite in its place, were there no other flower garden. But let it not be forgotten, that one of the chief charms of Latimers is the distinct interest associated with each of these three fronts of the mansion. Break up the fine breadth of lawn here and this diversified interest is gone. We hope the south front will remain as it is, a standing rebuke to the growing practice of sticking flower-beds here, there, and everywhere, to the destruction of everything like repose, rest, and breadth of view. The poet has sung of

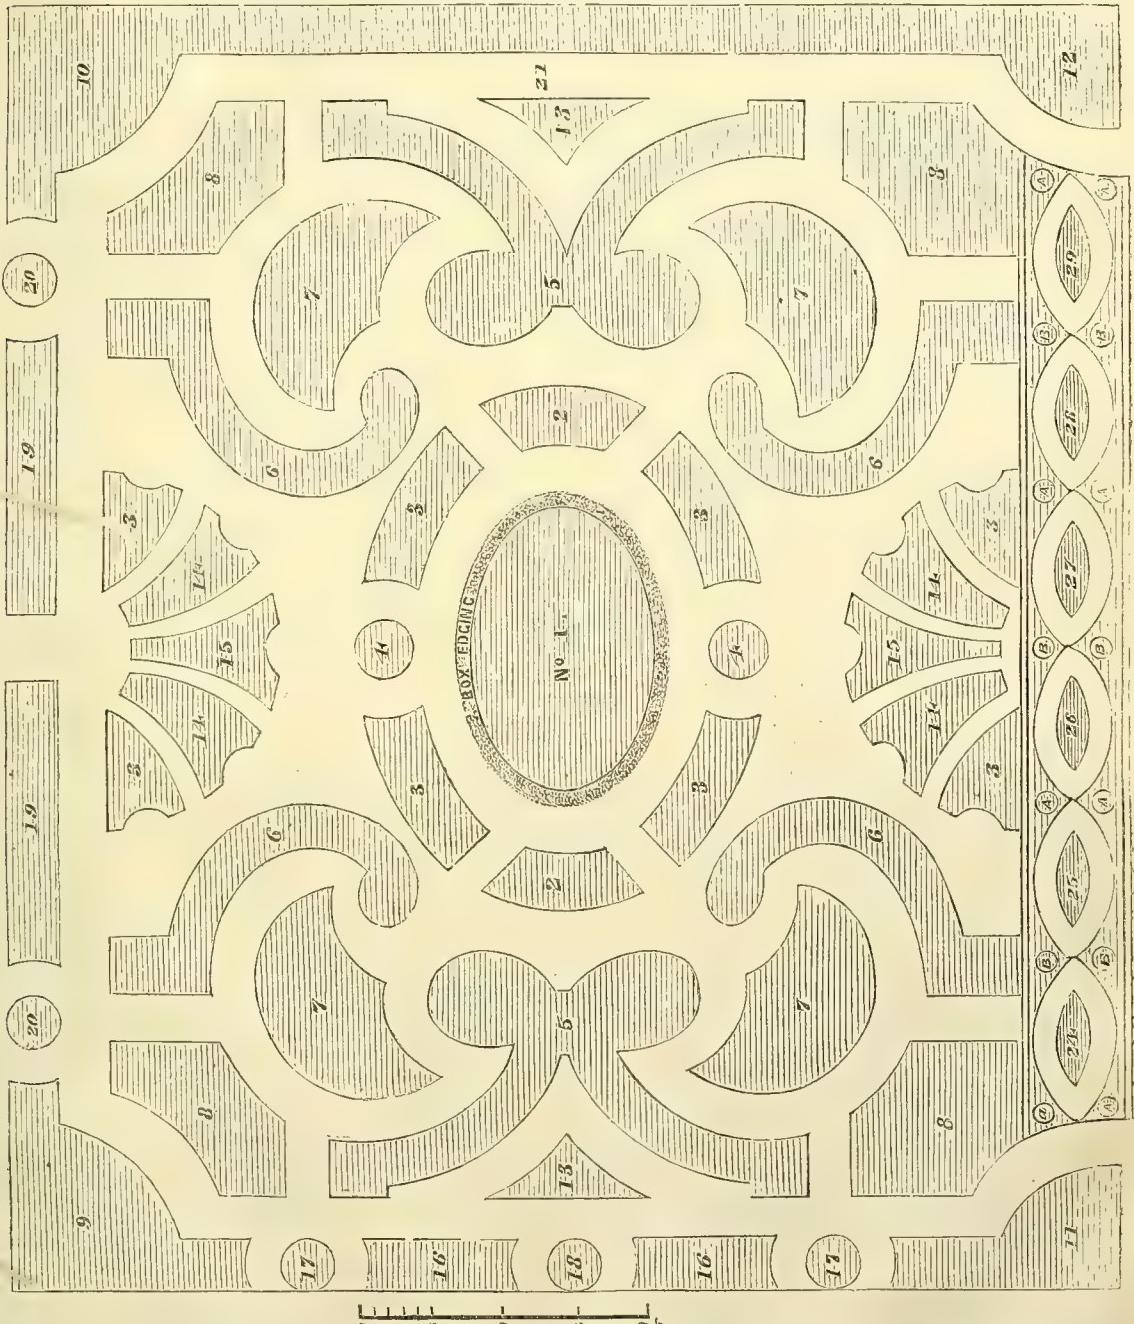

"Water, water, everywhere,
And not a drop to drink."

If we go on as we are doing, we will want another poet to sing of "Flowers, flowers, everywhere, and not a bit of green grass on which to stand and see them."

We now, however, leave this terrace and mount the steps to the flower garden on the west side of the mansion, this garden being on the same level as the upper terrace (2) on its south side. We had heard of this flower garden, and formed high expectations of it, as some of our readers may recollect what we said of the beauty of the flower garden at the Hyde when under Mr. Donaldson's management. The arrangement and the blending of colours were everything

1. Alma Geranium and blue Lobelia in rings alternately.
2. Stella Geranium.
3. Purple King Verbena.
4. Helen Lindsay Geranium, Boes.
5. St. Clair Geranium, edged with Christine.
6. Perle Geranium, edged with Cloth of Gold Geranium.
7. Frogmore Improved Scarlet Geranium, edged with Brilliant Geranium.
8. Aurea floribunda Calceolaria, edged with blue Lobelia.
9. Bijou Geranium centre, all round Attraction Geranium, next row Colets Verschaffelti, outside row Cineraria maritima.
10. Bijou Geranium, Trentham Rose, Amarantus melanocephalus, edged with Alyssum variegatum.
11. Bijou Geranium, Attraction, Colets Verschaffelti, edged with Centaurea transsylvanica.
12. Bijou Geranium, Comte de Morin, edged with Amanthus, outside row Alyssum.
13. Atrosto Improved Verbena.
14. Tropaeolum Eclipse (scarlet).
15. White Ivy-leaved Geranium.
16. Herald of Spring Geranium.
17. Madame Vaucler Geranium.
18. Magenta Geranium.
19. Rubens Geranium.
20. Mrs. Ferguson Petunia.
21. Ribbon — back row Anemones, middle row Countess of Warwick Geranium, front row Lobelia.
22. Fine Ivy-leaved Geranium.
- a, Cloth of Gold Geranium.
- b, Single plants.
- b, Colets Verschaffelti. Single plants.
26. Mimulus cyprius.
27. Verbena Duc d'Alençon.
28. Lobelia Paxtoni.
29. Fine Ultra (pink).
30. Heliotrope Etoile de Marquise.
31. Mimulus cyprius.
32. Lobelia Paxtoni.
33. Fine Ivy-leaved Geranium.
- a, Cloth of Gold Geranium.
- b, Single plants.
- b, Colets Verschaffelti. Single plants.

NORTH-WALL OF ROSES.

EAST-SIDE NEXT HOUSE.

that could be desired. The broad band of Box round the central oval told remarkably well. Did we wish to be hypercritical it would be to say that the small circles in the chain

pattern would have looked as well if all had been planted with the same thing. The four twists of Perilla were just high enough, but half an hour's nipping would have made

them perfect. A few days before the end of September most likely they were the right height, and most probably were so by the 1st of October. It was easy to see that heights were studied carefully, as well as colours, a matter of great importance in a symmetrical arrangement.

Being a distinct garden for flowers, what we have said above of breadth of view does not at all apply, as it forms of itself a separate feature of interest. Beautiful as it looked, however, and well as it was managed, two changes seemed to be necessary to render it complete. The garden is more a parallelogram than a square, being something like 38 yards by 34 yards. The whole plan is beautifully balanced and harmonious, with the exception of the four outsides, all of which are different. The two opposite sides should be the same. There need be no difficulty with the north and the south side. To make a handsome chain-border on the west side, as well as next the mansion, would require a little more encroaching on the lawn. To do this would necessitate the removal of a Horse-Chestnut tree at the north-west corner, more valued than its appearance would indicate—more especially as there are better and more interesting trees in the background; and also the taking away of a Beech tree or two at the south-west corner. The removal of these would also be an advantage to the high-keeping of the garden, as the leaves of the Chestnut soon begin to fall, and every yellow leaf in that garden would mar its beauty. Then, secondly, to secure the idea of completeness the garden should be distinctly bounded. This is done now on the south side by the terrace wall and vases; on the east side by the mansion, fronted by the broad walk of gravel, there being room for a similar walk between the garden and wall on the south side. On the north side there is the wall for Roses, the top of which meets the steep sloping bank of turf northward; but on the west side there is no boundary—no background to reflect and concentrate the brightness of colouring. A few yards of balustrading on the top of the north wall, close to the mansion, and in character with it, furnish the key note as to what is required. Continue that balustrading all along that north wall, a similar balustrading, but on a lower level, on the west side, and either continue it along the south terrace wall, or multiply the vases there by placing smaller ones between the rich stone sculptured ones.

(To be continued.)

R. FISH.

WORK FOR THE WEEK.

KITCHEN GARDEN.

MAKE it a rule never to allow the haulm, leaves, &c., of plants to remain on the ground when the crop is gathered, a convenient place outside the garden should be appropriated for the garden refuse; and before the leaves, &c., are wheeled to the heap, let a sprinkling of ashes or charred refuse be placed over each layer, by which a heap of valuable manure will be formed. While the ground is dry, proceed with digging up vacant spaces, throwing it into ridges that the land may be more effectually exposed to the influence of frosts. It should be a rule to double-spit or trench land every alternate year at least; but when two crops are taken off the same place yearly, trenching should alternate with digging each time the ground is cropped. *Cauliflowers*, as they are easily damaged by frost go over them frequently, and tie the leaves over the advancing heads. A portion of the less forward may be removed to spare pits or frames to succeed, or laid in deeply in a sheltered place, with their heads inclining towards the north, to be protected with straw or mats from frost. Cauliflowers under glasses or in frames may during the mild weather have air very freely. *Carrots*, having finished their growth should be taken up, and stored away for use. *Potatoes*, those that have been taken up and stored should be looked over and sorted; one rotten Potato will infect half a dozen. Others not yet taken up may now be dug. *Spinach*, go over the winter Spinach with the hoe, and follow with a dressing of soot. This useful winter vegetable requires strong stimulating manures to have it in perfection.

FRUIT GARDEN.

The planting of fruit trees either in the open quarters or against walls may be commenced as soon as we have a good

soaking rain. In planting odd trees between old-established ones against walls, a hole of considerable size should be made for the young tree, and refilled with fresh compost. In preparing new soil for planting fruit trees endeavour to keep it as dry as possible, and choose a dry day for planting that the soil may be in a favourable state for the growth of fresh roots during the autumn. The present time, after rain, is likewise the most favourable for relifting and root-pruning such trees as are too luxuriant and require checking, to induce a fruitful habit. We prefer lifting the trees entirely, unless they are very large, to cutting off the roots as they stand. After shortening the roots proportionately to the strength of the tree, spread them out near the surface, and fill in with compost, on which a mulching of half-rotten dung should be spread to prevent frost from penetrating the ground. Though the above is often necessary with existing trees planted in too rich or too deep borders, it should be borne in mind that it is only a palliative measure, and in the course of a few years will require repeating, unless measures are at the same time taken to make the border shallower or poorer, as the case may be. We are of opinion that wall trees would be more fruitful were their roots confined to borders of very limited extent compared with what is generally the case, and by which the balance between the roots and branches could be adjusted without the trouble and expense of root-pruning. Clear off the remaining leaves from wall trees to give the wood the advantage of sun and air to assist its ripening.

FLOWER GARDEN.

Before the flower-beds and borders have received the first shock from the approaching winter, the final remarks for the season should be made as to any re-arrangement of height, colour, or kind in the ensuing spring. This is more especially necessary when alterations of any kind in the design of the garden are intended. When the beds are cleared of decayed matter, a quantity of such biennials as the dark Wallflower, Sweet Williams, &c., may be planted, or bulbs for a late display. Let Dahlias, Carnations, and tender plants of all kinds be looked to, it may be necessary to pot some things for spring propagation. Ornamental climbers on trellises, arcades, &c., in blossom, should have protection on nights of a frosty character. Much valuable blossom may sometimes be insured by very simple means, as it not unfrequently happens that after one or two severe nights the weather becomes mild for weeks.

CONSERVATORY AND GREENHOUSE.

As the beauty of out-door scenery passes away before the storms of autumn, the conservatory should be made as attractive as possible, as it will now become in some measure the only place where flowering plants can be seen with comfort in unfavourable weather. To assist, let the requisite arrangements, both as regards watering and changing the plants, take place early in the day that the effects of the watering may be removed, and an agreeable dryness pervade the house before it is visited by the family. No pains must likewise be spared to keep the house gay, by introducing plants in succession as they come into bloom, including a portion of the stove plants which have been grown expressly for this purpose. A little gentle forcing will bring the different varieties of Epiphyllum into bloom, and with the addition of Chrysanthemums, late Fuchsias and Pelargoniums, Pancratiums, Amaryllis, Mignonette, Neapolitan Violets, &c., a tolerably gay appearance may be maintained until the time when forced plants will be more generally available.

STOVE.

The weather has been most favourable for ripening the succulent shoots of free-growing plants. When opportunity offers, therefore, do all you can to ripen the young wood, for it is in this way only that you can expect to get well through the winter. The temperature of the stove may now decline by night to 65°.

FORCING-PIT.

Keep the temperature of this structure by night at 60°, and increase it by day, if necessary by fire heat, 15° above the night temperature. This will assist Nature in flowering the few plants and bulbs which bloom in anything like perfection during dark November.

PITS AND FRAMES.

Everything should be finally arranged here as soon as

possible. See that the Mignonette has a very light situation, and is plunged close to the glass and free from drip. Store Verbenas growing freely should have their tops pinched, as also Petunias and other ordinary mass flowers. Give all the air possible. Intermediate Stocks intended for next year should be kept dry. Neapolitan Violets to have as much air as possible.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

PLENTY of rumours of rain, but none has fallen here. Watered Cauliflowers, Lettuces, Cabbages with sewage water. Tied and earthed up Celery. Gave also a little water to Scarlet Runners still fruiting beautifully. Covered and tied Endive. A capital plan where no glass protection can be given is to grow in rows from 2 to $2\frac{1}{2}$ feet apart, render it large by good treatment, tie up when dry, and then earth up, leaving only the top exposed. If in rainy weather a board is laid along the top the damp will be kept out. For common purposes nothing answers better for early work than giving the plants of the Large Curly a rough tie, and then placing slates, boards, or tiles along them. We generally, for all the flat-growing kinds, merely cover with boards, or place a few inches of dry tree leaves over them.

Hoed among young Onions, Spinach, Strawberries, Lettuces, &c., as the rougher and opener the surface the better will they stand all changes of wet or cold that may ere long be anticipated. As soon as we have time we will take up the most forward Carrots, Salsafy, Scorzonera, Beetroot, &c., as they keep so much better when taken up dry. Laid broken leaves over Cauliflowers, alike to keep them white and prevent frost from affecting them.

Mushrooms.—Had a piece more put in the Mushroom-house. Our beds under the thatched shed have done wonders, and are still producing profusely. We examined the bricks we made for spawn, and find it is running very slowly, and therefore made up a little bed of litter, and packed it on the bed to give it a speedier action. Much good spawn is spoiled by over-heat and over-wetness; but no good can be done without good spawn, unless we treat a bed so as to make it become a bed of spawn naturally, and to do that requires more time than we can spare in general.

We had an instance of this the other day. We generally put our Calceolaria cuttings into a low brick pit, the inside being considerably below the outside surface. But for this we would have done nothing inside; yet fearing that under the circumstances we might have too much damp, we placed about a foot deep of rather dry litter in the bottom of the pit, on which we placed the compost for the Calceolarias. When the Calceolarias were transplanted about March other things more tender were transplanted into that pit, and then after May the same place was used for plants in pots, low enough to stand under the glass, neither the litter beneath nor the soil being removed. Several times lately we noticed our man with armsful of nice Mushrooms from among the flower-pots, which would have been valuable if we had not the supply from the thatched sheds. On removing the surface soil almost the whole bed was a mass of run spawn. No doubt there had been a few droppings in the long litter, leaves, and stubble that formed the understratum, and most likely it contained spawn or spores; and here these had been extending ever since the end of October, 1863, and only began to produce Mushrooms freely a few weeks before we were under the necessity of clearing the bed out. That bed, covered with glass and protected from frost, we have no doubt would have produced heavily all the winter. Such masses of spawn are very good for placing anywhere, to obtain a little heat and moisture, and they will then produce well when slightly covered with earth. Such spawn is generally too far run to be useful for running in a fresh bed; but lots of Mushrooms may be obtained from it in an emergency by the above process, when it generally soon exhausts itself.

Tomatoes.—Gathered the last of these, which have been quite at home this season. A number of years ago we made some excellent sauce in a very simple way, simpler than any we have seen in the books, and we believe the recipe was in the Journal, but we have now forgotten it and cannot

find it. We knew there were a few bits of Capsicum, Horse Radish—a very little bit cut fine, and some Shallots, with pepper and salt to taste. Will some kind friend give a simple recipe, which without much trouble will give us a sauce that will stand over the most of the next summer?

FRUIT GARDEN.

The wind being very boisterous, and our friends the birds having commenced pecking our best Pears, we have gathered the greater portion of our fruit. Looked over, also, that previously gathered, and as we will want more room in pits and frames, have been wheeling out rotten dung ready to go between the rows of Strawberries, &c. As time permits, we will go on pruning a little, as it is more pleasant doing it now than in the depth of winter.

Orchard-house.—We intended shifting a few trees that are in smaller pots, but have not been able to touch them yet. We rather think we must wait for a wet day, when out-door work must be given up. As stated the other week, trees in pots from 13 to 16 inches in diameter, will want potting but seldom. We have had heavy crops of fine Pears in pots not more than 9 inches in diameter, and, of course, if to be continued these would require more room. For the larger size of pots, we are quite sure that the mode described by Mr. Rivers last week is the best—namely, good top-dressing. Our half or three-quarters plunging our pots was chiefly owing to deficiency of water, and to save so much watering. We are well aware that trees with pots exposed under glass, do not suffer from sun heat in summer so much as those exposed out of doors. Except some Cherries and Plums, few of the roots of our trees had gone above an inch or two from the pots. Not only did we thus plunge to keep the trees alive, but for a month or six weeks we covered the pots altogether with litter.

There is one little matter we would like to notice here. In the orchard-house, the latest one, we had some beautiful Ribston Pippins in September, flavour pronounced to be delicious; Plums, &c., the same. Then and since we have had fine-looking Pears, but we think the look was the best of them. They were not so high-flavoured and juicy as similar kinds grown out of doors, and ripened on the shelf of the fruit-room. Such, where grown in quantity, we would half plunge out of doors in a warm sheltered place after the middle of June. What do our practical men say? We also intended taking out our fine plants of Cherries in pots, but time went on, and there they are, and we begin to think from their appearance, and as we do not mean to force them, they are just as well where they are.

ORNAMENTAL DEPARTMENT.

Proceeded with securing greenhouse plants, hardening off stove plants, giving both all the air they could stand, and as soon as possible will remove Fuchsias, Begonias, &c., from the greenhouse, and rearrange for the winter. Examine bulbs to see that mice have not attacked them. Give all the air possible to hardwooded Cape and New Holland plants, but keep them secure from drenching rains, which the state of the barometer would indicate to be not far distant. General work, as to potting, cleaning, &c., much the same as in the last two weeks. We fear the high winds will sweep off the most of our tree leaves, which are falling freely, and when they go careering off into other people's lands, it is a great loss to us, and helps to keep us back for the next season. Were it not for these leaves the flower garden would still be fine, but to keep it free of leaves now would be like washing the skin of an Ethiopian to make it white. A month or five weeks ago, we noticed some men with brooms hunting stray leaves over a lawn, getting some half a dozen to lie down friendly together to be picked up by a barrow afterwards. Long before the barrow came, the leaves would dissolve partnership, and be trying to establish a fresh resting place on their own account. Such stray leaves as these would disfigure the nice lawn, and they might have been picked up individually and put in the gatherer's pocket at once, or in an apron or bag, sooner than half a dozen could have done it by the do-and-the-undo policy. Of course, when the leaves lie thick, sweeping and heaps must be resorted to; but in the great majority of cases, the making of heaps, to come and clear them up afterwards, is a mistake.

Calceolarias.—Our chief work of the week has been prepar-

ing for and inserting a great number of Calceolaria cuttings, to the preparation of which we have already alluded. We put in the bottom of the pit as much dryish litter as when well trodden would be a foot or 14 inches deep, then a couple of inches of half rotten leaves, also well trodden, then an inch of leaf mould, as we thought free of worms, mixed with the riddlings of the soil, then $2\frac{1}{2}$ inches of sandy loam, and a quarter of an inch of drift sand on the surface. Before the sand was put on the whole was again trodden, levelled, and slightly watered, as the material was rather dry; the sand was firmly beaten down, and the planting began. This season we plant them in rows 1 inch apart, and the rows are nearly 10 inches from each other. We like little short cuttings, about 2 inches long, taken off from the older stem with a heel; but you cannot always depend on getting them all with such qualities. It requires more time to take the cuttings off, and the lads will rather prefer having more time in the shed in making, than at the bed in taking them off. All amateurs who do most of the work themselves, we advise to spend time in the selection of their cuttings. There is little time afterwards required in making them, and though longer pieces, necessarily shortened, will often do well, they require more trouble and looking after than these short stubby pieces from 2 to $2\frac{1}{2}$ and 3 inches long. Cleaning the bottom, removing a leaf or two, and shortening one or two more are all that they require. When planted we water to fix them well, and for a long time a skiff from the syringe in a hot day, the glasses close, and air at night when not frosty will be all that they will require, as we would be best pleased if they rooted little until after Christmas.—R. F.

COVENT GARDEN MARKET.—OCTOBER 22.

Supplies of fruit continue heavy, with the exception of Pines, which are rather scarce, and of Peaches, which will soon be over. The principal dessert Apples are King of the Pippins, Ribston Pippins, which are very abundant, and Cox's Orange Pippin, of which there are excellent specimens to be had. Besides these there is great plenty of nameless Apples, such as are hawked about the streets. Pears for dessert purposes consist of Marie Louise, Crassane, Duchesse d'Angoulême, from the continent, and Beurre d'Anjou, a handsome new kind. The supply of Cobs is short this week, owing to holders keeping back; and vegetables are not so plentiful as they have been in former weeks. The Potato market remains unchanged.

TRADE CATALOGUES RECEIVED.

James Veitch, Royal Exotic Nursery, King's Road, Chelsea, and Coombe Wood, Kingston Hill.—*Plant Catalogue; Catalogue of Hardy Trees, Shrubs, Coniferae, American Plants, &c.; Catalogue of Select Roses.*

Charles Turner, Royal Nurseries, Slough and Salt Hill.—*Catalogue of Roses, Fruit Trees, Coniferae, Hardy Trees and Shrubs, &c.; Select List of Pelargoniums.*

TO CORRESPONDENTS.

. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

GUAVA (G. S.).—We believe yours to be the Psidium Cattleyanum. The purple fruit you enclosed was too bruised to judge of its exact shape, but the perfume and Strawberry flavour were that of the species we have named, *P. ferrugineum* we never heard of before.

FRUIT (C. W., Boston).—Write to Messrs. Webber & Co., Covent Garden Market.

PEAR LEAVES (C. E. L.).—They are attacked by a parasitical fungus. If you could collect all the affected leaves now and burn them, and do so when the fungus appears next year, you would extirpate the plague. It injures, but will not kill your trees.

MUSHROOMS (Silas Fixings).—Sowing salt over grass land early in autumn might prevent the occurrence of Mushrooms. We do not know the Elms in the Close of Salisbury.

HENSLOW'S DICTIONARY (Marfordie).—You can have it free by post for fifty-two stamps. The flowers were destroyed by the post-office punches.

ROSEY (A Lover of Roses).—It is, as you say, often spelt with an *a*, but having an English termination, we think the *e* is more correct. If the word had a Latin termination then it would be otherwise, as in *rosarium*. It is desirable also to have the spelling distinct from *rosary*, the name for the Roman Catholic string of beads.

DWARF APPLE TREES (E. M. W.).—Your overgrown dwarf Apple trees are doubtless grafted on the crab stock. No pruning will arrest their growth. The only method of doing so would be to take them up carefully in November, and reduce all their shoots to half their length, making their heads symmetrical. If they commence to make vigorous growth, say in 1866, they may in the autumn of that year again be taken up and replanted.

BOWLING GREEN (G. B.).—Our correspondent asks whether a bowling green should not rise 6 inches in the centre? We have always considered that a perfect level was the most desirable. It is so stated in *Rees's Cyclopaedia*, where there are very full directions for making a bowling green.

HEATING A CONSERVATORY (T. E. B.).—We have no doubt that Muzzett's plan would answer, and that of any other tradesman who advertises in our columns. Candidly, we take with the usual drawbacks all systems of hot water that are to do so much work at so small a cost. In all the plans we have worked we never found very great difference when continuously worked. A tall, conical, or tubular boiler would suit you and so would a flue along the centre of the house. We do not know the mode of laying out your $3\frac{1}{2}$ by 22 feet wide house, and whether span-roofed or not; but we have no doubt that the cheapest and most economical plan for merely keeping out frost would be a brick Arnott's stove inside the house. (*Stanley Hall*).—Much the same answer as to the preceding. Any of those tradesmen who advertise in our columns would do the work for you, or, if preferred, any blacksmith or plumber that has been used to it in your neighbourhood. We have no preference for systems, after having seen and tried most at work, except like the simplest best. A middle-sized saddle-back, or conical, or tubular-boiler will suit your purpose, and if your house is lofty, span-roofed and you wish to keep a temperature of from 55° to 60° in winter, you would require three pipes all round. If the house is a lean-to and you do not want so high a temperature, two pipes at the ends and front will be ample.

INARCHED VINE (Watton).—If you want to give due strength to the inarched Muscats you must cut away the head of the original stock. If you cannot well do this at once, take away a good portion of it, and the whole of it next year. As the Muscat shoot is so weak, cut that down to a couple of buds or so. The more strength of the stock you give it the better will it do. The flower was too faded and injured to be identified.

ARABIS LUCIDA VARIEGATA.—James Hoade, Addlestone, Surrey, wishes to know where he can obtain a supply of this plant.

EMIGRATING TO NEW ZEALAND.—"J. C." wishes to know if Strawberry plants can be packed so as to be taken out; whether tools should be taken; whether Quick thrives there; what kinds of seed should be taken; and whether settlers there grow their own grass seed? Answers to these queries, and any other information, will be acceptable.

VINES NOT BREAKING WELL (Finery).—We fear you have allowed too much fruit to remain on your Vines, which as you say are very young, and supposing you did the same last year, and then started to force early the past spring, the evil you complain of was very likely to happen. We fear we cannot give you any better advice than to cut them down below the blank caused by the buds not breaking, or even lower; but if plenty of canes exist you might let some of them remain as they are in order to produce some fruit next year. Buds that have missed breaking the past season will not break next, although most old wood is furnished with sets of embryo buds which only burst forth into leaf on being urged by some extraordinary cause—as the heading-down of the plant or other similar ordeal. We certainly caution you against allowing the Vines to bear so heavily another season.

DIRECTION (S. B.).—The direction is Stanley Bridge, King's Road, Chelsea.

INSECTS (G. W. H.).—Send us specimens in a quill or box, so that they cannot be crushed by the post-office stamps, and we will endeavour to tell you the names.

ADVICE (J. A.).—You appear to see the difficulties so thoroughly yourself as to stand in little need of advice. As to the vineries, we think it almost a pity to meddle with them; but dividing the range into three, instead of two, would enable you to have an early house next the boiler, with less consumption of fuel than you would need for a larger house. Secondly, As the range of vineries is only 61 feet, we think that taking out part of the glass in the centre, and forming a span-roof there from north to south, would involve considerable labour and expense, and do much to impair the usefulness of the vineries, and also to mar the symmetry which your employer values so much. Thirdly, On the west side of the vineries there is an open space, with a pit in front of it in line with the outside Vine-border, and west of the open space is an orchard-house, and we certainly would recommend you to have a house in that open space if it were not so wide as the orchard-house. This would be much better than interfering with the general outline of the vineries, such as having a span-roof in the centre of them, as we have frequently proved that putting up a new house is often an easier and less expensive affair than cutting, changing, and altering the appearance of an old one. Fourth, This plan would give you symmetry, as the pit you now have, with the new house behind it, would form the centre, the orchard-houses the west wing, and the vineries the east wing. Fifth, If you choose to increase your houses eastward, we do not see that, though the ground and the wall drop there, the new houses, being on a different level, would do away with symmetry. If so disposed on this lower level, making the vineries the centre, you might have the pit and house behind it, and an orchard-house as on the west side. Sixth, We question if you will heat much cheaper by one boiler, unless you choose to alter the position of the boiler—that is, on the supposition that you do not go farther eastward, and also on the supposition that the new house, pit, and vineries, are on a similar level. If so, if the late viney were changed into an early one, you could easily heat it and the pit from a boiler placed at the back of the viney, and without heating any other part, unless you liked. If the piping in the pit is on a much lower level, then, but for the unsightliness of the present stokehole in the path, that would be the best place for your one boiler. But, seventhly, If you contemplate having a house or a pit at the east end of a viney, and perhaps a house without heat farther east still, then it would be desirable to have the houses needing most heat at that end, and to place your boiler at the lowest part; and the simplest plan then would be to take a flow and return from the boiler to the farthest point you wished to heat, and then take flow and return from these to every house you wished to heat separately. By this means you would always have a little heat from the pipes in all the houses, but the flow and return need not be more than 3 inches, and when you did not want the heat you could give a little more air. This would be the simplest plan. If you increased the number of houses, however, you would require to have two boilers near together, in case you should have an accident with one. With eight or nine places it is a risk to depend entirely on one boiler. For such work we would prefer upright tubular or conical boilers. The lowering of the top lights of the viney, and making a hip instead, would so far lessen the length of the rafters. We see no advantage in doing so. We do not see how you could have the lights now at top, for what would you form the hip with? Surely not with an opaque hip—that would be worse still. We are obliged by your experience of Cloth of Gold. It has varied much this season. Perhaps Golden Chain has never done better than this year.

THORN HEDGES THIN AT THE BOTTOM (A Five-years Subscriber).—If they are too thin for a fence to prevent the intrusion of cattle, and you can dispense with them as such for a year or two, you may cut them down to 1 foot from the ground, and this any time from that at which the quicks are leafless to the middle of March, but the earlier the better. If the fences cannot be dispensed with for a year or two it would be preferable to lay the Thorns, cutting each stem 9 inches from the ground about three-parts through, and bringing the top down in an oblique direction, so that a fence 2 feet 6 inches or 3 feet high may be formed, crossing the smaller branches, so as to secure them in the position in which they are placed. In this way the hedge will become close at the bottom by the production of shoots below the cut part; but if the top be taken clean off a much better fence will be the result. There is no fear of frost injuring the quicks if they be cut in autumn.

MOVING COMMON HARDY FERNS (Rusticus).—If it be the common Bracken (*Pteris aquilina*), it is rather difficult of transplantation. To succeed at all with it select that which is growing the least, and dig it up in patches now, or from this time up to the appearance of young growths in spring, going so deep as to secure the underground creeping stems, taking up with the earth entire about them, and planting in the places desired. All other kinds of common Ferns may be taken up now with a ball of earth to them, or it may be deferred until March. If care be taken not to stab them up, but to preserve a nice ball to each plant, they will move safely and make quite a show in the first year, especially if they be planted in a little leaf mould, and have a good watering after planting if the weather be dry. If planted now they will not require watering.

HOYA CARNOSA CULTURE—PRUNING CLIMBING ROSES (Hoya).—The Hoya does well in a compost of turfy light loam, leaf mould, and peat, in equal parts, with about one-sixth of broken potsherds, or pieces of charcoal or other sharp sand. The drainage should be perfect, and occupy at least one-third the depth of the pot. It requires but little water in winter, and at other times about half the quantity given to ordinary greenhouse plants, as Fuchsias, &c. If an ornamental-foliated climber is wanted, there is nothing handsomer than the well-known *Cissus discolor*, and it likes a little shade; but if there is no shade from plants overhead, *Passiflora Decaisneana*, or *Stephanotis floribunda*, are quick-growing and fine climbers. Your management of the climbing Roses is quite right, and we cannot improve on your practice, except it be that if the old shoots are worn out they would be better displaced by younger shoots. In that case the strong shoots springing from the base of the trees should be allowed to grow trained in to the wall, and the old shoots cut away to make room for them, and eventually entirely removed. Our "Garden Manual" contains directions for the cultivation of the plants named, and may be had from our office free by post for twenty stamps.

PEACHES (Persica).—For late varieties procure Walburton Admirable and Gregory's Late. We believe that Mr. Osborne, nurseryman, Fulham, has Rust's Thames Bank Peach.

TRITONIA AUREA IN A POT DONE BLOOMING (J. L.).—Pot it now, and cut down the foliage to the surface when it decays. Keep dry, but not dust dry, during the winter, and shelter in a pit or cold greenhouse, from which frost is barely excluded.

SEEDLING PANSY (An Old Subscriber).—It is quite equal to many other varieties, but far inferior to the best now in our florists' lists.

MOVING HOLLIES—PLANTS UNDER YEW TREES (N.).—Hollies which have not been transplanted frequently will not move safely at any season, and we fear a worse time could not be selected than the present. Wet showery weather in April and May is the most suitable time. We know of no tree or plants that will grow under the shade of a Yew tree, except the different varieties of Vinca or Periwinkle, both green and variegated.

CONSTRUCTING A VINEY (A Novice).—You had better have the back wall 18 or 20 feet in height, as the front is 2½ feet. On that space of ground, 50 feet wide and 160 feet long, you could have about four houses, or five, according to the height. Thus supposing the first at the north end to be 18 feet in height, 20 feet in front of that you might have one 14 or 15 feet in height at back, and as you decrease the height you lessen the shade from the one in front. Your best plan is to erect poles of the proposed height of back and front, with a diagonal line representing the glass between them, and place these in a line from north to south, and see how the one does shade or not the slopes or glass of the house behind it. We could calculate this very nicely for you, and at much trouble might show how the house would be influenced by the shade in the different months of the year, but the sticks will show you all you want, and it is part of our system not to do for our friends what they can better do for themselves. Be assured that what the nurseryman told you is all nonsense. Of course, it is not to be understood that you are to force the vines the first season; but the glass will warm the soil as well as the atmosphere, and provided you give enough of air, plant with the glass on by all means, as it will help not only to give you better growth, but to ripen that growth sufficiently.

CLARKE'S GAS AND HOT-WATER APPARATUS (Yorkshire).—The manufacturer is Mr. T. C. Clarke, Eagle Iron Foundry, 25, Seel Street, Liverpool.

DWARF PLUM TREES (An Amateur Horticulturist).—Plum trees may be grown successfully as bushes; but, as no dwarfing stock like the quince for the Pear, or the paradise apple for the Apple, has been discovered for Plums, they are apt to grow too vigorously, even when their young shoots are pinched in to three or four leaves all the summer. This may, however, be remedied by taking up the trees biennially in November and replanting them. The central branches of your Apple trees may be shortened to half their length without injuring the trees. No injury can result from rain to the cut surface. The month of February is, on the whole, the best month for winter pruning fruit trees.

PLANTING VINE FROM A POT (B. T. E.).—The Vine turned out from a pot into a "curate's viney" will do very well, but it depends upon the growth it has made this season whether it will produce a crop next year.

BUDDED ROSES (J. P., Ellington).—Remove the bandages. Early in next spring cut off the shoot at two joints above the inserted bud, and when the shoot from this bud is about 4 inches long stop it. During May the two joints of the stock shoot may be pruned off close to the inserted bud.

BOOK (Read. J. M. F.).—McIntosh's "Greenhouse, Hothouse, and Stove" may suit you, but we believe the "Cottage Gardeners' Dictionary" is more easy for reference.

NAMES OF FRUIT (J. J. T.).—**Pears.**—1, Uvedale's St. Germain; 4, Ne Plus Meuris; 5, Beurré d'Aremberg; 6, Beurré de Rance; 7, Beurré d'Aremberg; 8, Beurré de Capianmont; 9, Easter Beurré; 10, Swan's Egg; Apples.—2, Warner's King; 3, Dutch Codlin; 4, Ribston Pippin; 5, Rotten; 6, Golden Winter Pearmain; 7, 8, and 9, Ribston Pippin; 10, Lewis's Incomparable; 13, Dutche Codlin; 16, Herefordshire Pearmain; 18, Lincolnshire Reinette; 19, Yorkshire Greening; 33, White Costin. Others not recognised. It is really unconscionable to send so many. (M. H. J.)—2, Fearn's Pippin; 3, Trumpington; 5, Devonshire Quarrendon; 6, Manks Codlin; 7, Yellow Inglistone; 11, Golden Harvey; 14, Passe Colmar; 15, Doyenne Boussois; 16, Besi Vast; 18, Brown Beurré; 19, Rotten; 20, Belle Apres Noel; 22, Forelle; 23, Beurré Diel; 24, Bergamotte Cadette. Others not recognised. (C. R.)—1, Beurré Diel; 2, Beurré de Rance; 3, Duchesse d'Angoulême. (Old Subscriber).—3, Hacon's Incomparable; 4, Beurré Diel; 5, Ne Plus Meuris; 7, Beurré de Rance; 8, Suffolk Thorn; 9, Gendesheim; 11, Emperor Alexander; 12, Api Rose; 13, Golden Nonpareil; 14, Franklin's Golden Pippin; 15, Golden Knob; 16, Tower of Glamis; 17, Gloria Mundii; 18, Dumetow's Seedling; 19, Borovitski. Others not recognised. The specimens were very fine. (G. H.)—1, Chaumont; 2, Flemish Beauty; 3, Chaumont; 4, Beurré de Rance; 5, Beurré d'Aremberg; 7, Ne Plus Meuris; 8, Beurré Diel. (W. G.)—2, Adams's Pearmain; 4, Golden Reinette; 5, Gravenstein; 8, Wyken Pippin; 11, Hughes' Golden Pippin; 13, Fearn's Pippin; 14, Reinette du Canada. The Pear is Doyenne Blanc. Others not recognised. (W. O. R.)—1, Trebbiano; 2, Prolific Sweetwater. The first requires more heat than the Black Hamburg.

NAMES OF PLANTS (A Nairnshire Subscriber).—It is *Stenocarpus Cunninghamii*. Its flowers are most beautiful, in candelabrum-like umbels, clothed with most vivid orange scarlet down. It does not bloom until it has attained a height of 15 or more feet; requires a greenhouse and abundance of light; is evergreen, and a native of Moreton Bay. (Constant Reader).—Your lemon-scented plant is *Dictamnus fraxinella*. (Stockport).—1, Hieracium crocatum; 2, Jasione montana; 3, Too young to be named; 4, Thrinia hirta. (R. H.)—1, Sericographis Ghiesbreghtiana; 2, Cannot be named as sent; 3, Dædalanthus nervosus; 4, Peristrophe speciosa. (A. L. Melville)—Agapanthus umbellatus, var. foliis variegatis, sometimes called Agapanthus variegatus in gardens.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS IN THE SOUTH.

We recollect the building of the Burlington Arcade. As it approached completion there were crowds at each end, and among them men of all callings, admiring and condemning, as the case might be. A butcher heard all that was said, and at once declared it was fit for one thing only—it would make a first-rate butchers' market. He saw it only as connected with his trade. We are apt to view all

places, when on our poultry-hobby, with an eye to their fitness for runs or shows.

We cannot tell the reason, but shows do not prosper in the south or south-west. During the winter the north has its weekly shows, which are well supported. They increase yearly; but in the south, and even in the south-west, they die a natural death. They had no lack of support; but, we believe, they were a sort of poultry "Do-as-you-likes" of the first category (see Kingsley's "Water-babies"), and so they went out, and, like them, have disappeared. People left off poultry in those parts, and descended to horses and dogs. Extremes meet; and so we suppose, as there are none now, they will be numerous by-and-by. We must wait, but, like Sancho's island, they are a long time coming. It is strange how people differ, and how supine the Anglo-Saxon, so enterprising in some things, is in others. He will compass the elements and surpass the labours of Hercules to do some great thing, but little things slip quietly by, and are unnoticed. Were it not that a certain per-cent-age of mankind is born fond of everything that breathes, and must find an outlet for a gushing sympathy for animal life, we do not think Englishmen would care for any fowl but a Game cock; nor do they care for breeding the lower order of quadrupeds, except as pets, or fancy things. In that little hive of a country, Belgium, Rabbits are reared as an article of food. In the suburbs of the towns, and in the towns themselves, there is no such thing as a stray or wasted cabbage-leaf or bad potato. The Rabbit-keepers collect all, and the result, as shown by recent statistics, is that 80,000 Rabbits, weighing above 200,000 lbs. of delicate food, are sometimes consumed in a week. This is a notable amount, and calculated for the year, gives large figures. All pains are taken to increase the size of these Rabbits; and the garden of one of the breeders of them shows every cabbage plant trimmed up like the elms in the hedges of some counties. It also shows a goodly heap of manure, the return for the waste vegetables consumed by the Rabbits.

The same care and painstaking presides over the poultry management. Every fowl is selected according to its fitness for the place where it is to live, and for the purposes to which it is applied. Being a Catholic country, there is a great demand for eggs. This, added to the fact that much of the soil is unfitted for rearing chickens, causes many of the non-sitters to be kept.

Attention to such details would enable many to have a paying hobby, would provide many a delicate Sunday dinner, and would add to the food produced in the country.

As a great lover of poultry, and a constant reader of your Journal, I feel surprised at your remarks on the Tunbridge Wells Poultry Show. I allude to the barndoors fowl, that "abomination of all abominations." This neighbourhood (I mean within a circle of ten or fifteen miles) is a great poultry county, and, I believe, sends more fowls to the London market than any other part of Sussex. From our railway station alone, some thousands are sent every week, and there is often a sum of £600 sent in one week from the Newgate and Leadenhall salesmen to pay for the fowls collected by one van. Of course, these fowls are bred in the neighbourhood, and yet not one farmer or cottager in a hundred keeps a pure-bred fowl. Some breeders say the more breeds are mixed the better and the hardier the chickens are. I have walked ten miles out and home in the earlier part of my "poultry mania," to see a place where only Spanish were kept. Pure-bred Dorkings are better known, and I have been pleased to see of late a growing liking for them amongst those who breed for profit only. As for Brahma, I look back with regret to the hours I have wasted in explaining to friends and poultry breeders what a Brahma fowl is. In fact, I finally gave up the breed in despair of ever meeting with any sympathy in this neighbourhood. There were two or three pens at Brighton Show last year, but no class for them, I believe, although I see there is to be one this year. I consider the scarcity of Polands and Spanish at the Tunbridge Wells Show is chiefly owing to the Show being but little known, as this is only its second year; also, the difficulty in reaching it from any point south of Tunbridge Wells. There are now many breeders of Spanish and other non-sitters near Brighton, and between

there and Hastings, who have no show within easy access, except the one at Brighton.

Your correspondent, Mr. B. P. Brent, would sweep all the beautiful varieties of Hamburghs into one class, with the euphonious title of everlasting layers, while with (no doubt his favourite fowl) Dorkings he would have no less than five classes, even dividing Silver Grey, Cuckoo, and Speckled. I agree with him that Dorkings must have the greatest number of classes in order to make southern shows a success; but the chief reason why there are not more of the non-sitters kept in the south, is the fact of hundreds of thousands of eggs being weekly, nay, almost daily received in the southern ports from the coast of France. These being sold very cheap, are, of course, disseminated in all the large towns in the south, and so quickly are they now brought over by steamers, that they are commonly sold in our watering places as "new laid." Until we cultivate and encourage the breed of "everlasting layers" more, I fear we shall not be able to compete with the French for eggs, if we do for chickens.—A THOROUGHBEED SPANISH, Uckfield, Sussex, October 19th, 1864.

I AM glad to see that the comparative dearth of poultry shows in the south, which I lately noticed, is attracting the attention of your correspondents. I should like very much to hear any suggestion from "Y. B. A. Z." whose letters I always read with pleasure.

One of your correspondents last week alluded to the absence of Brahma from the Show at Tunbridge Wells. If the authorities there and at Maidstone would only give Brahma breeders a chance of knowing when their Shows were to come off by an advertisement in your columns, I feel confident, from the experience of other Shows, that they would have a goodly muster of Brahma. The popularity of the breed is by no means confined to the great towns of the north, for at Islington, of the eighteen exhibitors who showed Brahma, fourteen belonged to the southern half of the kingdom.

Mr. Brent's suggestion that the Dorkings should be subdivided, and the number of Hamburgh classes diminished, seems justifiable from the experience of recent Shows; but the same test proves that in popularity the Brahma are surpassed only by the Dorkings, and when the relative encouragement given to the two breeds at many Shows is taken into account, it is found that the Brahma stand second to none. Spanish fowl certainly do not seem to be growing in favour; nor can I think that many, if any, poultry exhibitors desire with Mr. Brent the subdivision of the Spanish into Black, White, and Blue. The people at Dorking last year held a Show at which no fowls were admissible except Dorkings; but I cannot conceive that such complete subservience to the *genus loci* is deserving of imitation at other Shows.—BRAHMA POOTRA.

FROME POULTRY SHOW.

THIS was an exhibition of poultry held in connection with the Frome Agricultural Association in the private grounds of John Sinkins, Esq., close to the railway station, and though not large, contained some very good specimens. We hear that it is the intention of the managers to offer a more extended and attractive prize list next year; and we are quite sure they will meet with the success they deserve in so doing, for nothing could exceed their anxiety to please both exhibitors and the public. This was evident in all the arrangements; and especial credit is due to Mr. Charles Harding, the indefatigable Hon. Secretary.

The day was fine on the whole, and the numerous visitors must have helped to swell the exchequer, which offers promise of greater liberality and success on a future occasion.

DORKINGS (Any colour).—First, Mr. S. Lang, Redland, Bristol. Second, E. Baily, Calne. Commended, R. Elling, Sutton Parva.

SPANISH (Any colour).—First, A. Heath, Calne. Second, R. Elling. COCHINS (Any colour).—First, Miss J. Milward, Newton St. Loe. Second, J. Gardner, Bristol.

HAMBURGH (Pencilled, any variety).—First, G. Bendell, Wallbridge. Second, Rev. C. W. Edgell, Styles Hill House. Highly Commended, G. Bendell.

GAME (Any variety).—First, R. Elling, Sutton Parva. Second, Miss A. Elling, Sutton Parva. Commended, H. B. Festing, Maiden Bradley.

ANY OTHER DISTINCT BREED.—First, T. P. Edwards, Lyndhurst, Hants

(White-crested Polands). Second, J. Hinton, Hinton, near Bath (Brahmas). Highly Commended, J. Hinton (Brahmas). Commended, W. Miller, Sherbourne (Silver-spangled Hamburgs).

DUCKS (Any variety).—First, E. Ponting, Whatley (Rouens). Second, Marchioness of Bath, Longleat (Black East Indian). Highly Commended, E. Ponting, Whatley (Rouens). Commended Capt. Edgell, Boad (White Call). Commended, Marquis of Bath, Longleat (Aylesbury); T. Smith, Westbury (Rouen).

GEES.—First, Marquis of Bath, Longleat. Second, E. Jeffrys, Rye Hill. Commended, Miss K. Ashley, Sharpshaw Farm.

TURKEYS.—First, Miss J. Milward, Newton St. Loe. Second, T. Ashby, jun., Hazlett Hill Farm. Commended, Marchioness of Bath, Longleat.

EXTRA PRIZE.—Highly Commended, Capt. Ludlow, Heywood, Westbury (Chinese Silkie).

The Judge was Charles Ballance, Esq., of Taunton, Somerset, and the awards, we are told, gave entire satisfaction.

MONMOUTH FARMERS' CLUB POULTRY SHOW.

THIS was held on the 12th inst. Mr. R. H. Nicholas, of Malpas, a well-known and successful poultry exhibitor, consented to act as Judge.

SPANISH (Any age).—First, E. Shaw, Oswestry. Second, J. Pearce, Wyesham.

DORKINGS (Coloured).—First and Second, J. Skinner, Maindee. Highly Commended, E. Shaw, Oswestry. Commended, Miss A. Jones, Priory.

COCHIN-CHINA (Any variety).—First, Mrs. E. Everett, Gibraltar Cottage (White). Second, E. Jones, Newport. Commended, Mrs. E. Everett (Buff).

HAMBURGS (Gold or Silver-spangled).—First, T. Davies, Belmont Cottage, Newport (Silver). Second and Highly Commended, J. Skinner, Maindee (Silver-edged and Silver).

HAMBURGS (Gold and Silver-pencilled).—First, J. Skinner (Silver). Second, J. F. Clifford-Butler, Llanthilio (Gold).

POLANDS (Any variety).—First and Second, J. Skianer, Maindee (Golden).

GAME (Any age).—First, T. Davies, Newport. Second and Highly Commended, G. Pritchard, Llanvihangel.

ANY OTHER VARIETY NOT BEFORE MENTIONED (Any age).—First and Second, T. Davies, Newport (Minorcas).

BANTAMS (Any variety).—First, T. Davies, Newport (Black). Second, Miss G. Everett, Gibraltar Cottage (Silver-laced). Third, Mrs. E. Everett, Gibraltar Cottage (Game). Highly Commended, T. Davies (Black).

TURKEYS (Any age).—First, E. Bullock, Hadnock. Second, W. James, Lydard. Highly Commended, W. Williams, Filton. Commended, Mrs. E. Everett (White).

GEES.—First, R. Rees, Abergavenny. Second, Miss A. Jones, Priory (White). Highly Commended, Miss A. Jones; R. Rees.

DUCKS (Aylesbury).—First, R. Rees. Second, J. Skinner. Highly Commended, E. Shaw, Oswestry.

DUCKS (Rouen).—First, J. Skinner. Second, I. Theyer, Walford Court. Highly Commended, J. White, St. Weonards. Commended, Mrs. Elliott, Trete.

GUINEA FOWLS.—Prize, W. Philipotts, Trelersdee.

ISLINGTON POULTRY SHOW.

DEVOUTLY do I respond to the first part of your note to my remarks that we may meet at some future Islington Show, but I fear there is no such luck. I must simply dream of the many wrinkles I might learn from an hour's stroll amongst our pets in such company, and hope on. In my remarks I did not mean to say that I considered the schedule perfection. We ought not to forget that Islington is young, very young, but its growth has been very rapid, and in some respects she has set an example to her elders—in Brahmans, for instance. I do not think that Silver-Grey and White Dorkings at a Show of that calibre should compete in the same class; but you yourself have, I think, in by-gone Numbers, especially, if my recollection serves me, in your remarks on Birmingham in 1863, said that you saw no necessity for Silver-Greys having a class to themselves. However, I myself should not object to their having three classes; but am disposed to think that even in the southern counties five classes, as suggested by Mr. B. P. Brent, would in many cases form sorry exhibitions. Is your talented correspondent quite correct in writing as if the Dorking were peculiarly a southern-county bird? My skimmings of prize lists would induce me to say that the prizes very often go northwards—not unfrequently out of England—to wit, Mrs. F. Blair, Mr. J. Anderson, and others. It has always seemed to me but right that the Committee of really grand Shows should make up their minds to a loss on many classes, in order that they may obtain a variety—a collection, in fact—of the various breeds of poultry. Less Shows, such, in fact, as are held northwards, are usually tacked on to agricultural exhibitions, and generally prove the most attractive portion. This is their right place, and they generally succeed; but we southerners miss the manufacturing population, who

take the show-day as their holiday, who pay their shilling willingly, and whose payments fill the coffers of the Association, and make the speculation successful. Take Lord Tredegar's Show as an example even in the southern counties. I recollect the infancy of the poultry department—four pens of Cochins, shown by some gentleman at Chepstow; this was about twelve years ago. They created great excitement; there was no prize offered for them. The following year some prizes were offered, and some thirty or forty pens exhibited. These numbers gradually increased, although it was necessarily a local Show, as the Committee did not undertake the charge of the fowls. Well, what has it grown to now? A two-days show, with three or four hundred entries, and exhibitors from all parts of the country, many of our best breeders exhibiting. But here, as in the north, "the hills" furnish a large manufacturing population, and the speculation is, I imagine, a success: at any rate, the classes are yearly increased.

To Mr. B. P. Brent's further suggestion, that Spanish should have Black, White, and Blue classes, I say, Yes, by all means, when, like the Brahmans, they have fought the same upright fight, and proved that they will support such classes; but the experience of Islington seems rather against any increase of classes. Why, in the "pair of pullets" class, there were four entries only, and the second prize then withheld!

There are additions which I hope Islington will recollect—certainly a class for Malays, even though it be necessary, as our friend "WILTSHIRE RECTOR" says, to hide them that those only interested in the "uglies" may see them. I think I could show him some that would make him alter his ideas. Polands, any variety, is another mistake, certainly; but it must be borne in mind that it has been brought about by the supineness of Poland fanciers. Until they come forward more I could not advise a division into more than "White-crested Black" and "Silver and Gold."

Again: with great advantage to all parties, Geese and Turkeys might there be exhibited in pairs. Mr. G. W. Rawwell, certainly, has great cause for complaint; but if "prizes were thickly distributed to the members," there was one very glaring instance in the second-prize pen of Brahmans of a member not getting his deserts.

I have myself nothing to do with the Poultry Club—nay, as your columns prove, I have written against book-judging: therefore I am rather against the Club than for it; but if by their influence they can get up such a prize schedule and such a Show as Islington seems to have been, then I say we southern counties ought to be grateful to them.—Y. B. A. Z.

HACKLE OF SILVER-PENCILLED HAMBURGS —ROUEN DUCK'S LEGS.

I SHALL feel obliged by your informing me if there are any printed rules or book of the requisites for exhibiting poultry besides "Baily on Fowls," as I was yesterday at the Worcester Poultry Show, and saw the first prize given to Silver-pencilled Hamburgs, one hen having spotted hackles, and in another case a Rouen Duck with yellow feet, like a drake. I always considered, and Baily and all other books state, that the Silver Hamburg hackles must be pure white, and the Rouen Duck's feet black. I really shall feel obliged by knowing what are the rules and how to be obtained, as it seems hard on exhibitors if it is left to the whim or fancy of the Judge.—L. J. GILBY.

[Very rarely do we ask of a Judge a reason for his decisions, and when we forwarded Mr. Gilby's letter to Mr. Hewitt we told the latter gentleman we did not do so for the sake of enabling him to defend his awards, but to have his opinion about the hackle and the legs. His reply, however, enters fully into all the topics, and with his permission we publish it.

"I beg at once to assure your correspondent I was at the time of making the awards at Worcester quite as cognizant of the 'spotted hackle' in one of the Silver-pencilled hens as he himself was, and at the time regretted it; though I believe in the hands of a less scrupulous owner she would have been so 'improved' before sending out that she might have passed muster without any one observing it. I am perfectly aware that it was a failing; but there are many

other points equally important to success as the hackle in the Silver-pencilled Hamburghs, all which have equally strong claims on the attention of an arbitrator.

"I myself very rarely expect to find positive perfection even in a first-prize pen of birds if comprising three specimens. The awards, it should always be borne in mind, are made rather to the least defective than as an arbitrator's guarantee of absolute faultlessness."

"As to the statement that a Rouen Duck's feet should be *black*, I never before heard it propounded as indispensable or a desideratum. The true type of the Rouen Duck, of either sex, is admitted to be the Mallard and Wild Duck; size only always excepted. I myself never saw a Wild Duck nor yet a purely-bred Rouen with *black* feet. At first, as young ducklings, both breeds have dusky legs and feet, but on the attainment of the second feather they always assume a colour very closely resembling that of a Seville orange, sooty on the webs; and this hue they afterwards retain for life, subject, as in all birds, whether aquatic or otherwise, to becoming much lighter coloured during moulting time, and after long laying. Again: the intensity of colour in all waterfowls' legs and feet is greatly dependant on whether they enjoy free access to water, or the contrary. No adult purely-bred Wild Duck has black feet, nor am I aware of any domesticated variety of Duck with black legs and feet, except the East Indian, though several of the smaller wild waterfowls are very closely approaching to it; but not so the true Wild Duck.

"Your correspondent has a considerable variety of books on poultry to choose from. The original 'Poultry Book' is expensive; then comes 'Dixon on Poultry,' and 'Nolan on Poultry,' and a very cheap little work named 'Poultry Book for the Many,' published at your office, and any of the others can be obtained through a general bookseller.—EDWARD HEWITT."

COWS ROBBED OF THEIR MILK.

IN reply to your correspondent "J. J. T." and your answer to his query, I beg your insertion of the following fact. About eight years since I had a cow who somewhat suddenly ceased to give more than the smallest quantity of milk. After nights and days of watching, we found she was regularly milked by two strong pigs, whose wonderful condition at the time was a mystery to us. I do not know anything about hedgehogs milking cows, and never heard of such a thing.—TRENT.

UNITING QUEENS TO STOCKS—UNITING BEES.

I HAVE much pleasure in submitting to the aparian readers of THE JOURNAL OF HORTICULTURE the following letter from the esteemed correspondent whose failure with a Ligurian queen was related in page 225, and to whom I sent a second queen in place of the one which met so untimely an end.—A DEVONSHIRE BEE-KEEPER.

"DEAR SIR,—I am glad to say that the queen and bees arrived quite safely at Albrighton yesterday (October 10), at 3.27, and also that I successfully united them to the stock which had been previously prepared for their reception.

"When the box arrived I noticed that it smelt strongly of what seemed to me to be heather honey, and I feared that the peculiar smell might render the strangers obnoxious or distinguishable to my bees. So having removed the lid I substituted a piece of perforated zinc, and after bringing the queenless stock into the house inverted the small box over the aperture in the crown-board, and allowed them to remain in this position all night. In the morning I placed the Italian queen with two only of her own subjects under a small bell-glass, and admitted one bee from the stock. It appeared not to take much notice of the queen, but having just touched her a little with its antennæ, left her alone. A second bee was then admitted, which, marching up to her majesty, at once seized her by the root of the wing. I instantly interfered, and crushed the hostile bee, still adhering tenaciously to the queen. I then thought I would try the effect of peppermint-scented syrup; and having taken the hive to its accustomed stand, blew a few whiffs of tobacco smoke underneath the crown-board, and sprinkled the bees bountifully with the scented syrup, and, replacing the crown-

board, allowed them ten minutes to lick up the syrup and settle themselves. At first I thought of sprinkling the Italians also with the syrup, and then slowly admitting the bees from the stock to the queen and bees altogether; but on consideration, thinking it would then be difficult to see what the disposition of my bees might be towards the person of the queen, I determined to make a second attempt as before. The result was most satisfactory. The bees at once acknowledged the queen (whom I also had daubed with scented syrup), so that in about one hour I felt justified in allowing the queen to descend into the hive. Subsequently I sprinkled the Italian workers, and allowed them to enter at the doorway of the hive. No fighting ensued, but a perfectly harmonious union was effected. I have just united the discarded hybrid queen to a stock of black bees. Had the second bee used its sting instead of its teeth a repetition of the previous tragedy would have occurred.

"I think sprinkling bees with scented syrup is a good preparation both for uniting queens and bees to strange stocks, and for this mode of proceeding I am indebted entirely to you. I have effected many unions with bees in this way with invariable success, no fighting taking place in the hive; but a little (not much), has sometimes occurred on the following day, owing to the hesitation with which the strangers alight at the entrance. If adjoining hives are united, and the conjoined bees are placed between the original sites, both being equally puzzled, fighting has not ensued.—J. E. B."

VARIATION IN LIGURIAN BEES.

I HAVE a hive of Ligurian bees, the queen of which is breeding differently-coloured workers. Some of them are brilliantly marked, while others are quite dark, the orange-coloured stripes being scarcely visible. Will you tell me whether this is a common occurrence, or the result of a cross with a black drone?—A. N. B.

[The queen of your Ligurian stock has been hybridised by a black drone, which is no very unusual occurrence. You have yourself accurately described the mongrel breed, which results from the cross between the two varieties.]

BEES CARNIVOROUS.

"I AM very jealous," Dr. Cumming observes, "for my bees," and so am I, sir, and I do n't relish the idea of their being flesh-eaters, any more than that of my honey having been brought home in the same "sac" with horse beef. Alas! for our old-fashioned notions; how they go one after another, as the world grows wiser! Why, I should have fancied, sir, that the turkey drum-stick which "RUBY" saw inside a hive covered with bees, was undergoing the process of mandible-scraping as a sanitary precaution; or that it might be destined, like the "Bee-master's" snail, to receive propolitan sepulture.

Before I saw the article on this subject in your Journal, I would as soon have believed in a hybrid between a wasp and a bee, as in the carnivorous propensities of the latter. I wonder, by-the-by, whether "RUBY's" bees had any peculiarity either in the cut or colour of their coats, which would at all countenance the notion that there might be a dash of vespan taint in that hive. Since reading the article alluded to, I have tried my own bees with flesh, and some that were hungry, too, but they turned away from it with disgust. I took care to have it dressed with the "gravy in," and no salt, but they recoiled from it, with, as I thought, surprise and annoyance. Mutton, beef, rabbit, hare, it matters not, they will not even touch it. One or two old fellows made a rush at it, at first, and after giving it a few raps with their antennæ, turned round and eyed me full in the face, as if in contemplation of an "odd fish," for which I suspect they took me for my pains. However, if they do not know the value of "fibrin" in imparting strength to the constitution, I mean to teach them, and I mean, sir, to adopt this system, at least, I offer it as a suggestion, subject to your approval. I shall make some strong beef tea, thickened with calves' feet jelly, and flavoured with "Scotch ale."

The idea of a patent food for bees has crossed my mind

once or twice, and if I had or could obtain a great name and high sanction, perhaps I might make a venture which would raise my humble blush to a par with Thorley or De Jongh. By-the-by, I wonder what became of the propolitan mausoleum in which Dr. Cumming's snail was interred, what kind of snail it was, and what it did during the somewhat slow process of living sepulture? Truly it must have been a snail of wonderful patience, and the bees must have worked even with more than apian alacrity.—RUBY BLUSH.

FOUL BROOD.

In again taking notice of foul brood, let it be distinctly understood that it is not for the purpose of resuming a discussion on it, but simply to state what I have observed since my last communication. Let others do the same, and then we may hope to find out its cause and cure. I trust that what I have to say, though it partly relates to what I have seen in my neighbour's apiary, will not be deemed the less interesting on that account.

1st. When the bees arrived from the heather last autumn and it was found that all his hives contained foul brood more or less, he drove the bees out of three hives (uniting them at the same time), cut out all the combs, except in the three hives, and carefully selecting all those which had no foul brood, put them in a clean straw top or super. He supported them with sticks, and placed the super on the top of an eke of empty combs, but containing a good swarm of bees which I had given him, and which had been always free from foul brood. In the spring of this year when we examined it there was a considerable quantity of foul brood both in the super and eke. We also observed a few drone cells diseased. This was the first occasion on which we had ever observed drone brood affected. We then drove all the bees into a clean empty hive, which was taken to the heather with the others.

2nd. The three united swarms alluded to he kept for ten days in an empty hive, and then put them into a hive of empty combs which I gave him, but quite free from disease. The two when examined in the spring after the bees had swarmed and all the young brood was out, were found to contain a quantity of foul brood. The bees were driven into a clean empty hive, as in the former case, and sent to the hills. Since they came from the heather they have been examined as well as his other hives, nine in all, and I am glad to state that not a single foul-brood cell has been seen in any of them. This is the more remarkable, as his hives had it more or less every year for ten or fourteen years. Those bees were fed with honey from diseased combs.

I have now to report what has occurred among my own hives. It will be remembered that last year foul brood made its appearance for the first time in one of my hives, a Neighbour's, and when seen it was at once destroyed, bees and everything. The disease again made its appearance in three of my hives this spring, but in none of the others, and, strange to say, it was in those bars I had taken out of the hive which contained the queen I had received from Mr. Woodbury last summer. The bars were taken out and put into hives containing black bees for the purpose of raising Ligurian queens. One of the bars had fifteen cells on each side diseased, the others not so many. I removed the bars at once, but allowed the bees to take the honey they contained on the outside of the hive. I have examined every bar I possess since they returned from the heather, but could not find a single diseased cell in the whole stock.

Could it be the queen I had from Mr. Woodbury that had brought foul brood all the way from Exeter, and so polluted my apiary? or is it some weakness or defect in the stocks wherein it appeared? But why speculate? I confess its cause is still as mysterious to me as ever.

In my neighbour's two cases one had clean bees put among combs taken from where the disease was, though those combs were free of foul brood, and it was even carried down to the eke of clean combs. In the other case the bees though taken from among foul combs had been kept in a clean empty hive for ten days, then put among clean combs, and were still diseased. In my own case could a single queen bee be the means of conveying this disease? Who can say? To ascertain what effect a sudden reduction of temperature

would have on a hive full of young brood, from a common cottage-hive containing a good swarm, and the bees lying out as if about to swarm, I drove out all the bees, caught the queen, put her back among the combs along with a few bees, certainly not more than five hundred, placed them about 40 yards from their old stance, and put in a bar of eggs from a Ligurian queen among the driven bees, placing it on the old stance that they might rear another queen. I had left so few bees along with the queen and young brood that for ten days seldom a bee was to be seen issuing from the hive, and though I gave them food they did not take it for ten days or more. While the hive was in this state I had a delicate thermometer made with a long bulb, and the tube 6 inches in length beneath the scale, and inserted the tube between two combs in the centre of the hive, 6 inches down. It happened at the time that the weather was extremely cold for the season, the external temperature being as low as 48° at night, while the thermometer inside the hive indicated 63°, seldom rising above 75° for fourteen days, I certainly expected nothing else but a mass of corruption, but after two weeks the bees began to go out and in, and had wonderfully recovered before they were sent to the hills; so much so that I put on a super, but previous to doing so I turned the hive up, and found that all the brood had been hatched. I could see no foul brood. When the hive came from the hills I took off the super containing 15 lbs. of honeycomb, having made 19 lbs. in all while at the heather. The hive is still free from foul brood.

In February of this year, I had thermometers, the same as the one above, placed in three Woodbury-hives, just when breeding commenced. The bulbs were inserted between the bars where the brood was, and the temperature was frequently as low as 48°. On the 15th of February one thermometer indicated 45°. The temperature gradually rose during the summer, though not rising and falling quite so much as out of doors. The thermometers remained long at 95°, and when they rose to 97°, the bees lay out. I never observed the temperature above 97°, unless the bees were disturbed, when it would rise to 120° or more.

I was asked by an old bee-keeper who had kept bees for more than fifty years in the old straw hives, to look at one of his which was not thriving. On turning it up I found it a mass of disease. I observed what I never did before, the young grubs unsealed-up, some of them nearly black, others streaked with black lines as if with pen and ink. There were also numerous drone grubs in the same state, and but few bees, which seemed not to be able to seal-up the brood, as it was seen in all stages diseased. It was the worst case I ever saw. The queen appeared to be active and healthy. The whole was destroyed.

I may also state that foul brood has made its appearance this year in the hive of a neighbour, who has been always free of it hitherto. It was only a few cells. I know of only one person in all this neighbourhood whose hives have not suffered more or less, and great numbers have entirely lost their stocks; but I hope a better day is coming for all. This season has been so good that the spirits of bee-keepers are again reviving, and should we have such another season next year, I doubt not but many who have managed to bring their stocks through the crisis, will be rewarded for all their perseverance and discouragements by a demand for stocks. To show the great decrease in the number of hives in this locality, in one place on the hills where I have counted 450 hives in former years, this year there were only 37.

I had fourteen hives at the heather this year, and they gathered 353 lbs. of honey, being on an average 25 lbs. each. The highest made 37 lbs., and the least 15 lbs. The fourteen hives contained 689 lbs. of honey, bees, and comb. The heaviest hive weighed 104 lbs. The like result has not been obtained in this quarter for a number of years.—ALEX. SHEARER, *Yester Gardens.*

THOSE among the readers of THE JOURNAL OF HORTICULTURE who have perused my communications on "Foul Brood, and Those who have Written about It," will be aware that the illustrious Schirach considered that this disease might arise from the queen depositing her eggs in a reversed position, so that the young bees, unable to extricate themselves from their prison, die and putrefy. In this opinion he was followed by the Abbé della Rocca, Huish,

and more recently by the aparian writer in "Chambers's Information for the People." The notion of young bees finding themselves with "their heads where their tails should be," appeared to me so whimsical, that although I certainly discovered a defunct young queen in this position in a royal cell in a foul-breeding hive, I paid little attention to the circumstance until reminded of it by "A RENFREWSHIRE BEE-KEEPER," and assured by him, that he had found diseased pupae in this extraordinary predicament. Since that time I have only once had the opportunity of examining perfect pupae in a diseased state, and in this case they were unquestionably inverted, their heads being in contact with the bases of the cells. On advertizing to this circumstance in my correspondence with that accurate observer, "R. S.," I find, however, that he is unable to affirm it, and as I hope to have no further opportunity of investigating the point, I mention it in THE JOURNAL OF HORTICULTURE, on the chance of Mr. Shearer or some other correspondent being able to throw light upon it.

Whilst on the subject of foul brood, I wish to express my acknowledgements to Mr. Tegetmeier for directing my attention to Bonner's quaint and interesting description of this disease which appeared in page 303. I quite agree in the opinion privately expressed to me by an esteemed friend, that "it is creditable to British apiarists, that a disease so prevalent as foul brood appears to be, has not altogether escaped their attention."—A DEVONSHIRE BEE-KEEPER.

WINTER FEEDING.

Is brown sugar moistened with a little water, or rum and water, and pressed firmly into basins and turned over the top of the hive, a good plan for feeding bees in the winter? —M. F.

[We never before heard of, and of course have never tried, this plan of feeding bees, but cannot say that we are very favourably impressed with it. We believe winter feeding to be a mistake, and consider that the necessary supply of food should always be administered in the autumn.]

THE SQUIRREL IN CONFINEMENT.

WHEN a youth, this pretty little animal was a great favourite with me, and after some failures I succeeded in keeping one five years in the best of health. The most wholesome food I found to be a piece of bread, the size of a large walnut, steeped for about two minutes in milk, in such condition that he can hold it in his hands; "pap" I found invariably gave squirrels the rot, and they never survived long on such diet. In addition to the bread I kept in his cage a small pan of hempseed which he was very fond of, and allowed him to drink from a pan of water as much as he liked once daily. Nuts, fruit, and green buds he had as a treat occasionally. I have had squirrels so tame that they have lived in my pocket, and have gone with me wherever I went, and the pretty little fellows have had many a ramble in the fields and on trees, always returning at the shaking of a few nuts. Like most tame favourites, however, a violent death was generally their fate, so I was induced to restrict their liberty, and latterly confined them mostly in a cage. It is generally considered that a revolving cage is torture to a squirrel, I must differ entirely from this. On the contrary, it is a source of great delight and exercise. If the wheel by any means was stopped, the distress of the squirrel was extreme, and a gleam of pleasure could be plainly seen in his large bright eyes when it started again. There are two facts which struck me as contrary to the generally-received habits of the squirrel—the first was the extreme reluctance of the animal to jump; even half a yard in any direction but downwards required a very strong temptation, and nothing would induce a squirrel to jump where he could climb. I have noticed this peculiarity both in confinement and when at liberty. The other point is, no squirrel that I ever was acquainted with would eat acorns; they would seize them eagerly, nibble them, and drop them in disgust.—JOHN HUNTER, New Malden, Surrey.

NEW ENGLAND APPLE-SAUCE.—Make your cider of good, sound, ripe apples, and immediately on its running from the

press, and before it has an opportunity to "work" or ferment in the least degree, put it into good, clean, brass, kettles (they must be scoured and cleaned perfectly bright inside, the old verdigris and rust is poison), and boil it four barrels into one. Take good, ripe, sweet apples—(Tollman Sweetings are the kind I used), of the late fall or winter varieties—pare, quarter, and core them; then take a pan-full and put into your kettle of boiling cider, and let them cook through but not soft, so that the quarters retain their shape and size, and skim them out with the skimmer, and put them into the barrel, or whatever the sauce is to remain in—which, by the way, must be perfectly clean and sweet, or free from acid. When the apples are all cooked, the cider in the kettle will be somewhat reduced in strength, and must be boiled down to the state to keep well, and then poured into the cask with the apples, in sufficient quantity to cover them well and to have plenty of juice in the sauce when used.

In making true New England apple-sauce and boiled cider, much depends on having the cider boiled instantly on its running from the press, as it begins to ferment the moment the apples are mashed; and the warmer the weather, the more haste should be made, and also the stronger the cider should be boiled down, even six to one. In boiling the cider, if it should be necessary to defer boiling a part of it overnight, for want of time to accomplish it all in one day, it should not be allowed to remain in the kettle overnight, nor to stand in it when not boiling for any length of time, as it will attain a poisonous acrid taste. Care should also be taken not to boil so as to burn or scorch the cider on the sides of the kettles. When boiling the cider, all impurities should be skimmed off, especially just as it arrives at the boiling-point. The proportion of apples to cider must be to your own taste, whether thick with apple or thin with cider. If too thick with apple, more cider may be added at any time after; and also if the cider is boiled down too thick which cannot well be done in this warm climate, it can be reduced with water as used.—(Prairie Farmer.)

OUR LETTER BOX.

ISLINGTON PRIZE LIST.—We are informed that the Silver Cup for the best pen of Game was awarded to Mr. E. Aykroyd's first-prize Duckwing chickens.

WEAKNESS IN A DOBBING COCK (A. N. B.).—Give him bread steeped in strong ale every morning and evening. Feed him on ground oats in the middle of the day. The most certain restorative is to give him the yolks of raw eggs, three or four every day, but it is a dangerous taste to encourage.

UNFERTILE EGGS (*Subscriber*).—You probably have too many hens to the cocks. The eggs you mention are unimpregnated.

DEPRAVED APPETITE IN FOWLS (*Guernsey-Blue*).—It is not an unusual thing at this time of year, during the moulting season, for fowls to peck off each other's feathers and eat them. It arises from a fevered state of body, and a craving after unnatural food. They seek to eat the bleeding stub of the feather. The fowl appears well, and we are always advocates for leaving a bird alone; but if you wish to cure him of his cough, we think a dose or two of castor oil will do it. Lettuces are very good for heated systems.

DIET OF POULTRY (*Poultry Fancier*).—Our theory has always been the same, and it has stood the test of many years of breeding. It is, during the period of growth to feed as well as possible, in order to supply the means of increase. Although in most instances pullets cease to grow when they begin to lay, that is only as regards the scaffolding; but the furnishing of plumage, and the filling-out of frame then begins, and although growth ceases, there is a constant increase of weight. Many amateurs consider spare feeding that which we should call luxurious. Scantily-fed chickens cannot make large hens.

DISTINGUISHING GANDERS FROM GEESE (W. X.).—Examination is the certain test of sex in Geese. There is sometimes difficulty even in this. You should ask the Judge who disqualifies your pen. He will tell you his grounds, perhaps.

BOLTON GREYS (*Bolsover*).—This is the local name for the Silver-pencilled Hamburghs. They are a distinct variety and come true to colour. They will bear confinement in a small space. They are one of our best egg-producers, but seldom are broody.

WOODBURY AND STEWARTON-HIVES (*Cornwall*).—Messrs. Neighbour and Sons, 149, Regent Street, and 127, Holborn, and Mr. R. Eaglesham, Stewarton, manufacture, and will on application state prices of Woodbury and Stewarton-hives respectively. We can recommend no others in preference to these. We are unacquainted with the hive you mention, and shall be glad of a description of it.

LONDON MARKETS.—OCTOBER 22. POULTRY.

Trade is very dull at market. The supply is ample.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 53.2°, and its night temperature 37.5°. The greatest heat was 64° on the 2nd, 1857; and the lowest cold, 19°, on the 3rd, 1861. The greatest fall of rain was 1.62 inch.

DECORATION OF THE FLOWER GARDEN
IN WINTER AND SPRING.

(Continued from page 308.)

FLOWERING SHRUBS.

F these the most suitable are evergreen, but some of the finer kinds of early flowering deciduous shrubs are very desirable. Few exceed the splendid *Berberis Darwinii*; its foliage is handsome; it blooms freely in April (earlier against a wall and in warm situations), and its fine racemes of golden drop-like flowers render it one of the finest shrubs we have. A bed of it is unsurpassed by any yellow-flowering plant or shrub at that season. But the loveliest of all yellow beds is that formed by the tiny-foliaged, yet dense, dwarf, *Berberis empetrifolia*; and not less beautiful is the gorgeous *Mahonia aquifolium*, which has handsome foliage and fine heads of yellow blossoms. The Berberries are easily cultivated in pots, and do well in a compost of light loam and leaf mould in equal parts. The first-named forms a fine bed of from 1 to 3 feet high, the *Berberis empetrifolia* one of from 1 to 1½ foot high, and the *Mahonia aquifolium* beds of from 2 to 3 feet.

The early-flowering kinds of *Erica* or hardy Heaths form admirable beds. The best low rose-coloured bed that it is possible to have for spring-blooming is one of *E. carnea*, and that known as *E. herbacea*, a flesh-coloured kind, little differing from the preceding. Then there is *E. mediterranea*, with pink flowers, which is handsome in habit, and makes a fine bed from 1 foot 6 inches to 3 feet high. The above, though doing best in peat soil, will thrive in ordinary ground, and, forming close balls, will move freely twice a-year—to the beds in October, and to summer quarters in the last week in May, only they must be kept well supplied with water after removal.

Kalmia glauca, a free-flowering dwarf shrub, with reddish blooms appearing in April and May, makes a nice bed. It likes peat, and so do all the American plants, and these are admirably adapted for planting in groups, the foliage being as effective as the flowers, which, as is well known, are amongst the handsomest we have. They all form close balls, and on this account may be transplanted with as much certainty in May or June, immediately after flowering, as at any other period of the year, it being desirable at that time to plant them in prepared beds of peat soil; but in autumn they may be removed to the flower-beds with as much soil adhering to the roots as possible, and planted in their winter quarters in ordinary soil, where they will bloom nearly (I think quite), as well without as with peat soil. They certainly are grown more safely in pots in sandy peat soil. *Ledum thymifolium* and *L. buxifolium* are dwarf and dense in habit, and form admirable edgings. They

are very pretty when in bloom, the blossoms being pink in bud, and expanding of a clear white. The variegated form of *L. thymifolium* makes a handsome edging, little more than 6 inches high. *L. latifolium* is a fine shrub from 1½ to 2 feet high, and its balls of white bloom are remarkably pretty in April and May.

Andromeda floribunda is by far the best of the Andromeda family, producing its pretty, wax-like, delicately-scented blossoms in great profusion in March and April. It is one of the best plants we possess, and is both handsome in foliage and habit. The flowers are white. A nice match-bed for this lovely shrub may be formed of *Pernettya mucronata*, which has handsome foliage, and rather small, drop-like, white flowers. Some of the early-flowering *Rhododendrons* might also be employed. *R. caucasicum album* blooming early, and being of dwarf habit is admirably adapted for the purpose. *Rhododendron Nobleanum* and *R. atrovirens* are also very suitable. *Rhododendron ponticum variegatum* also makes a nice bed on account of its foliage. *Coronilla glauca*, with fine yellow flowers borne in great profusion, though usually found in greenhouses, is hardy enough to do well in sheltered situations, where it makes a bed of the loveliest description, and its variegated form (*C. glauca variegata*), is indeed fine. They will, however, only do in some localities. What is more curious and effective in its way than a bed of *Ruscus hypoglossum* or Double-leaved Butcher's Broom? Examine its bloom, and though the flowers are green, it is both singular and attractive; then, for forming a really gorgeous golden bed, *Ulex europaea* (Furze), single and double, will compete with anything of the same colour. They should be grown in pots in rather poor sandy soil.

For the beauty, as well as fragrance of their flowers, *Daphnes* may be planted, and of these any of the following are suitable:—*Pontica rubra*; and the striped form of the species (*variegata*), *D. cneorum*, with pink flowers, and its variegated form, which has pink flowers in addition to variegated foliage. The Daphnes should be grown in pots of sandy loam and peat, in equal parts, with free drainage. To these may be added several *Cotoneasters*, as *Simmondsi*, with the finest of scarlet berries in autumn and winter, and *C. microphylla*, by no means despicable as a plant for surfacing beds, and for edging others, affording berries in winter and flowers in spring; as standards on four-feet stems they are also ornamental. *C. rotundifolia* or *C. buxifolia* (I could never see any difference between the two), is suitable for a bed, and a standard or two will look well if judiciously placed. *Laurustinus* (*Viburnum tinus*), is another evergreen flowering plant that must not be overlooked, a bed or two of it will have a handsome appearance.

After these come deciduous-flowering shrubs, and when we have *Jasminum nudiflorum*, which is sure to flower at Christmas before the leaves are produced, and give a golden mass for some time, we have a fitting companion for the Christmas Rose, which I will note ere long. This Jasmine succeeds admirably in a pot of loam and leaf

mould in equal parts, and will flower as well on a wall with a north aspect as in the sunniest situation. *Rhodora canadensis*, with purplish blossoms in April, and which likes a pot and peat soil, and *Forsythia viridissima* and *suspensa* with their yellow trumpets, tell well. *Magnolia conspicua*, though attaining the dimensions of a tree, is not out of the way as a bush or pyramid pinched in like Apple or Pear trees, it being well supported by M. Soulangiana, and finely contrasted with M. *purpurea*, or *obovata* of some. *Ribes sanguineum*, *aureum*, and the white variety tell effectively when in a mass, and they grow so well in pots, and bloom so freely, even when small, that it is a marvel that they should have escaped being employed so long when there are so many empty spaces for them. *Moutan Paeonia*, too, in endless variety, bloom so much earlier when grown in pots as to be eligible for spring decoration. *Anemone botryapinum*, treated as a bush Apple, is a sheet of snowy white in April or May; and managed on the same principle, the *Amygdalus persica flore pleno* and *flore albo*, *camelliaeflora*, *coryophylliflora*, *rosea*, and *versicolor*, double rose, blush, pink, and white, are all fine. They require the pot-treatment of the Peach. And what is handsomer than the gorgeous scarlet of *Pyrus japonica*? It and the white-flowering kind, also the double, are all destined to occupy a prominent position in the flower garden in spring. I do not know whether they are common shrubs or not, but it is rare that we see any of the Buckthorns, but most of them flower from April to June, and though the flowers are only greenish yellow, yet these shrubs are very fine. They may be grown as dwarfs, and pinched-in like some Pear trees. The only one that has white flowers is *Rhamnus frangula*. Why should we not also have *Chimonanthus fragrans*? which is most fragrant and likes peat soil; and we ought not to say our beds must remain empty for want of something to put in them until we have taken the last plant of *Chamaelodon procumbens* from off the Scotch mountains. It is a trailing Azalea, not more than 6 or 9 inches high, with pink flowers in April and May. It requires a sandy peat soil.

Most of the foregoing are best grown in pots in the compost recommended for each, and where none is mentioned, it is to be taken for granted that they will grow in ordinary soil. All plants in pots require good drainage. This should, therefore, be provided, and water furnished before the want of it is indicated by the foliage. Under rather than over-potting is desirable to induce flowering more than growth. Evergreens in pots will need little water from November to March, and deciduous shrubs none during that period. At other times they should not be allowed to suffer from want of attention to watering, and it must be borne in mind, that the bloom of any plant will last longer when a plentiful supply of water is afforded.

G. ABBEY.

(To be continued).

THE NEW ROSES.

As usual, from all quarters the question is asked of me, "What do you think of the new batch of Roses? what would you advise me to have?" and as usual I feel how very difficult the office of a prophet is. I cannot look back with much satisfaction to the manner in which I fulfilled that office last year; for on referring to THE JOURNAL OF HORTICULTURE, where I ventured to give my opinion as to the Roses of the future, I find that out of the eleven which I fixed upon as likely to contain the best, three only promise now to be among the first rank. Less fortunate in this respect than Mr. Radclyffe, I may indeed perhaps this year hope to be a little more successful, for I happened to be in Paris at a better season; but even this is not much of a boon. Any one who has gone over in the hope of seeing the French seedling Roses knows how difficult it is to effect this. Either you are too early or too late, or, *malheurement*, the nursery is so far off that you obtain very little information. Then the raisers of Roses are so scattered that it would require a long time to go through them all, and thus even those who go to far more trouble and expense than I did are disappointed in their researches.

I am still strongly of opinion that we must trust rather to the character of the raisers than to the glowing descriptions of the French lists. With that pardonable love for one's own children which leads many an English raiser of

florists' flowers to overestimate the beauty of his seedlings, they can see nothing but the most brilliant! remarkable!! splendid!!! magnificent!!!! varieties in their productions; and many of them, I am afraid, if they contrive to sell them, do not much concern themselves about our disappointment, or rather not ours, but those of the growers for sale. Amateurs rarely purchase until the second year, and then they have had the opportunity of seeing or hearing something about the kinds with their own eyes and ears; and by the autumn following their *début* a tolerably fair winnowing of the inferior ones has taken place. Following as nearly as I can the plan that I adopted last year of classing them under their respective growers, I shall, omitting the wonderful and in some cases incomprehensible descriptions of them given in the French lists, briefly sketch their characters, and say where I have seen or heard such reports as give one good reason to hope favourably; and first, then, with the Paris raisers.

CHARLES VERDIER.

So far as I can ascertain, there are only two Roses to be let out by M. C. Verdier this year, and one of these I know to be good.

1. *Duchesse de Caylus*.—A very well formed globular Rose, of crimson scarlet colour, and of vigorous habit. I am very much mistaken if this will not be found to be amongst the best Roses of the year.

2. *Duc de Wellington*.—A brilliant velvety red, darkly shaded; centre of the flower lively red.

EUGÈNE VERDIER FILS AÎNÉ.

When I was in Paris M. Verdier very politely brought me his seedling Roses to see at the hotel where I was staying. It was after that tremendous storm of the 18th of June had burst over Paris, deluging everything and beating down the heads of the poor Roses; and besides, several of them were only under numbers. There were these, however, which I selected, and they are likely to be valuable acquisitions. I may add, too, that I went through part of his seedling ground, and saw there many hundred varieties rejected which a year or two ago would have been thought superexcellent.

3. *Rushton Radclyffe*.—An odd combination of terms, unless we are to style our reverend brother as the Scotch do, the Radclyffe of that ilk, or drop the name and call him Rushton, like "Lochiel" or "Islay." Well, the Rose is a fine one, of the style of Madame Victor Verdier, very full and clear, with no shading, and I shall be very much surprised if it do not take a leading position.

4. *Auguste Rivière*.—Lovely carmine red; reverse of petals paler; edge of petals light.

5. *Comtesse de Paris*.—Lovely currant red; full.

6. *Docteur Andry*.—Beautifully imbricated; lovely carmine red. Very good.

7. *Général d'Hautpoul*.—Flowers in clusters; lovely scarlet red. I think this is the one that I had marked as next in merit to Rushton Radclyffe. If so, it is likely to be a valuable flower.

8. *Madame Verschaffelt*.—Plant almost thornless (I do not know that this is any particular merit); well-formed flower, beautiful tender rose.

9. *Souvenir de William Wood*.—A flower said to bear a likeness to Prince Camille de Rohan, only darker. If this be a correct description I did not see it; but one that is said to be an improvement on that fine variety must indeed be desirable.

MARCOTTIN.

10. *Charles Margottin*.—I see that my excellent friend only announces two flowers this season, and of these I have only seen the present Rose. It is a very large, brilliant, and showy flower, one of the very brightest I have seen, and I should think likely to be a valuable Rose.

11. *Mademoiselle Amélie Helphin*.—Lively carmine rose, well formed, and large.

MAREST.

12. *Duchesse de Medina Celi*.—Some two or three years ago, before Marest removed to his present nursery, driven out by the increase of buildings in Paris, he told Mr. Stan-dish and myself that he had a grand Rose to let out: if this be the one it will, no doubt, be one of the best of the year. At any rate he has raised two Roses which ought to give him credit—Prince Léon and Comtesse Cecile de Chabriant, and

only these, as far as I can recollect. I think that we may then hope that the Duchesse, which is described as shaded blood-red purple, may be one of our best Roses.

LEVEQUE ET FILS.

13. *John Veitch*.—A very lively red; well formed; the plant very vigorous.

14. *Madame Eliza Vilmorin*.—Very free flowering. A curious Rose, somewhat puckered on the edges. I saw these Roses at Paris in the summer, but I cannot say that I was greatly prepossessed with them. And now for some of the Lyons Roses.

LACHARME.

An honest good raiser, who has every year sent us over something good, and whose judgment as to a Rose we may consider to be tolerably good.

15. *Madame Charles Verdier*.—A beautiful vermillion Rose, described as being between Baronne Prévost and Duchess of Sutherland; and if so, likely to be a very great acquisition. We want Roses of this character, and if Lacharme says that it is good, we may well give him credit for it.

16. *Xavier Olibo* (which I have no doubt will come to be called "Holybones").—This is described as a large, well-formed, velvety black Rose, amaranth shaded; and I dare say it will be amongst some of the foremost Roses of the season.

GUILLOT, PÈRE,

Another raiser, to whom we are indebted for many good flowers, has this year some which promise well.

17. *Capitaine Rognat*.—A cupped, very full Rose; brilliant red.

18. *Madame Portier*.—Tender rose. Not very large flower.

19. *Monsieur Moreau*.—Beautiful purple Rose; flowers globular.

20. *Triomphe de la Terre des Roses*.—A beautiful violet Rose, very fragrant. Let us hope its name will be significant of its beauty.

It is difficult to say what these colours are, for I find the same colour oftentimes most differently described, or to what flowers they bear any analogy. They sound well, and 17 and 20 especially so. Let us hope they will sustain M. Guillot's character. I find I must defer further criticisms till next week.

A word, however, first as to Mr. Radclyffe's communication. I did not enter into the subject of white and light Roses generally, but only as I was asked, those of the Hybrid Perpetual class, or I should certainly have referred to those which he has mentioned. Madame Macker is an unknown flower to me, so I can give no information concerning it. I am more than ever convinced that we must, in speaking of Roses, especially as to their hardiness or otherwise, make our observations conditional. Thus, Mr. Radclyffe says Virginal requires a wall; but it does not do so with me—it blooms and grows very well in the open border; while, strange to say, I have had Madame Rivers half a dozen times from various growers, and yet have always lost it, although I have in most places seen it growing in great vigour.—D., Deal.

LATIMERS.

(Concluded from page 336.)

In concluding our notice last week we left off at a bank, passing over which, and by the nice specimens it bears of *Pinus*, *Wellingtonia*, *Cypress*, *Abies pinsapo*, *Hollies*, and *Yews*, mingled with older deciduous trees, we reach a flower garden on the north side of the offices and mansion, and concealed from them by a dense thicket of *Yews*, *Hemlock Spruce*, *Hollies*, &c. This garden has a large fountain in the centre, with large flower-beds round it, and might have been a very pretty spot before the surrounding trees threw over it so much shade. Mr. Donaldson spoke of its being transformed into a fernery, and there are plenty of nice young *Yews* to continue the boundary all round, so that the place would not be seen until you entered it through an arch of *Yew* or *Ivy*. Roots and puddingstones were being collected for the purpose, and a few *Pineuses* on the higher points that will be thrown up, in addition to the surrounding boundary, will give a nice shade to the Ferns. A few *Alpines* and fine-foliaged plants among the Ferns will add

to the effect of the latter, and thus another distinct feature of interest will be formed within a few minutes' walk of the mansion. From the reservoir of water, forced up from the lake, water might grace this fernery as well as the elegant flower garden.

Passing hence through the pleasure-grounds, we reach the stables and the kitchen garden, the former a fine block of suitable buildings, but which there is some idea of removing farther eastward, so that the present road to them may be shut up or made strictly private. The kitchen garden, of about 3½ acres in extent, has the outside walls here covered with masses of *Laurels*, and, if the contemplated change take place, Mr. Donaldson expects to cover these walls with fruit trees. Under present circumstances the effect is very good.

Of the kitchen garden we must say little, as our critical gossip has been rather lengthy—gossip which, if it yield little pleasure, will, we trust, be equally powerless to give any offence. Notwithstanding the dry season, we found fine quarters of vegetables for present and for winter use, and among them a new curled *Bérecole* from Mr. Veitch, which seemed to be an improvement on the Scotch Cabbaging Kale.

Among the fruit trees we noticed some nice trellises of strained wire, about 3½ feet in height, for *Gooseberries* and *Currants*, the trees in both cases being clustered with fruit-buds. We know of no plan so suitable for small gardens, a great amount of fruit of the best quality being thus obtained, whilst the ground between may be cropped with low vegetables. Such trellises, too, are easily protected from birds and wasps. Mr. Donaldson also assured us of a striking fact, that though the wasps attacked without mercy the *Gooseberries* grown as bushes, they did not at all interfere with those grown upright on the trellis. All the Apples and Pears by the side of the main central walk were root-pruned last season, the Apples to be kept down as low dwarf bushes, and the Pears to be grown in the pyramidal form, and all were bristling with buds and short-jointed wood. The trees against the walls had either been renovated, or taken up and replanted, or root-pruned with good effect. There were whole quarters of *Strawberries* in pots, most of them in 24's, each pot standing on an inverted saucer, with free space all round, and the plants were the finest and strongest we have seen for years—in our opinion just too strong; but no doubt they will produce fine masses of fruit. Of other sorts, Mr. Donaldson, for the main supply, prefers President, which he considers like Keens' Seedling, but greatly superior to it under glass.

There were a small Fig-house or two, a small and a large Peach-house, a span-roofed viney in which the roots had been lifted, a Paxton-house for the million for various purposes, but with an upright glass front as far as we recollect, and the flap or cap between each two sashes capable of being raised at pleasure for the half or the whole of the length by a simple lever. The back wall of this house had several broad shelves, so that by these, in addition to the platforms, a great number of things may be stored. The main range of vineries is divided into three or four houses of good size—one pruned, one in which the wood was ripe, one planted with *Muscats* doing well, and one filled with fine *Hamburgs*. These, fine as they were, did not satisfy Mr. Donaldson; and he had cut out several Vines at one end, hanging the fruit in the fruit-room, and planted fresh ones, after having made a fresh border for them. He can draw some of the old stems over this part next season, and thus by degrees he will renovate this fine house and never lose a crop. These vineries are 17 feet wide, 17 feet in height at back, and about 1½ foot in front. The borders outside rise pretty well to the water spout, and by the end of September were all covered with strong wooden covers, tarred or painted, to keep heat in and cold and wet out.

Among flowers, not to speak of pits, frames, small houses, &c., we found a nice greenhouse and stove. But we must mention only one thing about the plants, and that is, that the greenhouse was rendered more beautiful by a number of pots of *Convolvulus* or *Ipomæas* of almost every shade of colour, and tint, and stripe, the plants being allowed to twine about a branch or the top of a young tree fixed in the pot. These climbers in pots made a most attractive feature.

Out of doors we found fine plants of *Chrysanthemums*.

The dry weather and the grub had spoiled a border of China Aster, in the culture of which Mr. Donaldson used to excel; but as a consolation to us we noticed a nice border of herbaceous and bedding plants, and were informed that this border belonged to Lady Chesham, whence she could gather flowers without interfering with the beauty of the rich parterre near the mansion. Something of this kind should always be provided where cut flowers in quantity are a daily desideratum. Nothing will so thoroughly paralyse energy and effort, as finding a first-rate ted of yesterday transformed into little better than a wreck to-day, through this person and that being permitted to gather flowers from it at pleasure.

One other fact, and we finish the account of our morning's inspection of this interesting place. On walking up the bank from the pleasure ground we observed cast metal pipes in trenches not yet filled (the joints, we think, closed with lead), for transmitting water from the reservoir in a higher position to the stables, garden, mansion, offices, clergyman's house, &c. This water of the reservoir is brought up the hill from the lake by the action of a water-wheel. We did not see the wheel as the place was locked, but we saw Mr. Metcalfe, the able superintendent of the farm, and his water-wheel was going, and helping to thresh, cut, grind, saw timber, &c. The water to turn this wheel is brought across through the wood by a wooden culvert from the lake, and over what is called the old stream, which acts as the tail course to the farm wheel. Mr. Metcalfe would like more power, but the cascade is only high enough to give him a breast instead of an overshot wheel. The wheel that drives the machinery for the supply of water to the mansion is entirely in a chamber beneath the ground level, and the tail water comes out beneath the cascade. If the water is too low to drive this wheel a horse can be employed to work the machinery. The cascade is a fine feature with the water foaming and frothing over it, but it is apt to be dry when the farm wheel is worked during the day. Raise the cascade some 18 inches, which raising would necessitate but little alteration in the present banks of the lake, and far enough back transfer the waters of the old stream into the Colne; and not only would much more power be given to the wheels, but, as the old stream would supply as much water as is now taken for working them, the cascade with its tumbling and sparkling waters would be a thing of beauty every hour of the day. We need scarcely add that neatness and good culture were everywhere conspicuous.

The first word in the sixteenth line of the previous article, page 333, should be "winding" instead of "building." — R. FISH.

PROPOSAL FOR A ROSE COMMITTEE AT PARIS.

How can the inundation of new Roses from the continent be stemmed advantageously to the English growers? Facts go to prove that out of the fifty new Roses annually sent to this country not more than five or six live over three years in the public mind, or are worthy of a place as distinct varieties in any respectable Rose catalogue.

While I believe that the years 1866 and 1867, from the great heat of the present and last season, will place English raisers more on a level with their neighbours, something in the meantime must be done to prevent English growers and amateurs from being quite disgusted and discouraged in buying new Roses.

I would propose for consideration that a committee to protect the interests of the Rose be formed in this country, much on the principle of the Fruit Committee of the Royal Horticultural Society, to consist of say twenty of the first Rose growers, to sit at Paris every month during the Rose season. To carry this out a Rose Society would require to be set on foot, each member subscribing a fixed moderate sum to defray expenses, including the sending out monthly three or more of the above committee to preside at the meeting in Paris, and give certificates of merit and prizes for the best new productions. The English judgment and taste would thus be better met, confidence restored, and time and money saved, as it would not then be necessary to grow in quantity hundreds of "novelties" two years before they can be faithfully recommended for our gardens. The

minds and pockets of honest nurserymen would not be hurt by consigning hundreds, nay thousands of the well-grown new Roses annually to the faggot-pile, where they ought to be carefully put to make room for better varieties.

Looking at the great and deserved love England has for her Rose, I consider this subject, which I have but feebly laid before your readers, worthy of the earnest attention of the Royal Horticultural Society, and of all who are interested in our national flower.—HENRY CURTIS, *The Devon Rosery, Torquay.*

LARGE PEARS.

SEEING in the Journal what the Rev. S. Reynolds Hole, of Caunton Manor, near Newark, can produce from the *Conseiller de la Cour* Pear, I beg to enclose you a slip taken from the *Dumfries Standard*, to show what can be produced from the Duchesse d'Angoulême. The weight of the eight Pears was 7 lbs. 14 ozs.—GILEEET TWEEDIE.

"A fruit-bearing Pear tree was shown by Mr. T. Tweedie, and is quite a prodigy. By a process which Messrs. J. Palmer and Son have carried out with singular success, the tree is dwarfed in size, so as to gain in produce what it loses in stature; and this specimen (a Duchesse d'Angoulême) has, under Mr. Tweedie's careful management, proved so prolific that, though little more than 4 feet high and growing in an 11-inch pot, it displayed eight immense Pears; one measured nearly 12 inches round, and weighed 14 ozs.; another, of rather greater circumference, weighed 1½ lb.; the rest of the crop being worthy companions of these individual specimens.

"When at Annan, we had an opportunity which we gladly embraced, of viewing the garden and greenhouse in which Mr. T. Tweedie practises with so much success as an amateur horticulturist; and we feel sure that if merchants and others of his class saw what he accomplishes with considerable care, but at comparatively small pecuniary cost, the luxury of a greenhouse would be much more generally indulged in. A few rare exotics figured amongst its contents, and from the roof hung quite a harvest of Grapes, similar to these large specimens which lent opulence to the exhibition. An aviary near by vied in attractiveness—we might almost say bore away the palm from even the fruitful viney. Such a collection of the feathered tribes is, we suspect, not to be readily found elsewhere in the possession of a private gentleman. In a shed—we cannot call it a cage—20 feet by 9, were more than a hundred birds, from the redbreast, the lark, the blackbird, the thrush, and others of a commoner kind, to the goldfinch, canary, starling, and pheasant, all manifesting a loving fellowship with each other, and forming such an interesting, happy family as was delightful to behold. An Oak stump in the centre, and various shrubs in other parts of the aviary, form the roosts or resting-places of the plumaged race, and there they were seen hopping from twig to twig, or taking a larger flight across, enjoying comparative freedom, and evidently in the highest comfort and health. A golden pheasant is the paragon of the entire establishment, and the creature, though superlatively handsome and most superbly attired, assumes no haughty airs, and lives in amity with the humblest of his brethren. The owner of this unique feathered republic is Mr. G. Tweedie, who, we suppose, feels as much pleasure in presiding over it as his brother does in his horticultural products."

LARGE CROP OF PEACHES.

In 1863 I ripened on eight trees 1600 Peaches, many of immense size; and in 1864, the same trees produced and brought to perfection 2500 Peaches not so large, partly owing to the drought. In the year 1863, about 4000 Peaches had previously been taken off; and in 1864, at least 5000 were also removed.

The eight trees are on a wall with a south-easterly aspect, have been about eighteen years planted, and have generally borne most abundant crops. In consequence of the fruit being for some years destroyed by spring frosts, I had a covering of thin canvass placed over them. In the first year when removing the canvass, I found an abundant crop of fruit but no leaves; these had been destroyed from keeping the covers over the trees night and day. In a short time fresh leaves came out, but all the fruit gradually disappeared.

In the following year I removed the covers every fine day and some fine nights, and the result was a splendid crop of fruit. This same result occurred several years in succession, until the sheets being weakened by age were entirely destroyed by a heavy shower, and the trees were that year unprotected. However, the spring being mild the crop was good. In the following spring when the trees were in full bloom, a heavy shower completely washed away the pollen, and in that year also I had not a Peach. Next winter I placed a temporary coping-board about 12 inches wide over the trees and left it there until about June, when the rain would be serviceable. The result was, that in that and every succeeding year I had splendid crops. This simple and cheap mode of protecting the trees I conceive to be far the best. I need only refer to the crops of 1863 and 1864.

An Englishman writing in a contemporary this year, says he had 510 Peaches on three trees, whereas I had 1124 on my two largest. I hope that the publication of this note will call forth remarks from Peach-growers, and I am anxious to know whether others have exceeded what my gardener has accomplished.—T. DALY, *Fair Hill, Cork.*

[We do not understand the measurements of the trees which bore these extraordinary crops. Mr. Daly in another letter says:—One tree, 23 feet by 10, 230; two, 20 feet by 10, 400; two, 20 feet by 10, 400. Whole length with eight Peach trees 128 feet. Now, as five trees occupy 103 feet, then only 25 feet are left for the other three.—E.D.]

NEW ROSES FOR 1865.

I BEG to acknowledge with thanks the receipt of Rose catalogues from Mr. Rivers, Sawbridgeworth; Mr. Cranston, King's Acre, Hereford; Mr. Cant, Colchester; Mr. Cattell, Westerham; and M. Eugène Verdier, Paris.

On perusing the lists of our own countrymen, it is satisfactory to find the improvement they exhibit by the rejection of large numbers of inferior kinds, with which they have in former years been too much burdened, to the no small perplexity of purchasers and the disgust of rosarians; there is yet room for further improvement, which it is hoped that the experience of another year will suggest. As it is, Mr. Rivers's catalogue is so carefully compiled that there is indeed little to complain of, and very much to praise and be pleased with. By not inserting the novelties of the current year, of which it is impossible, as well as unfair, to speak with certainty till they have been sufficiently proved, Mr. Rivers has acted quite in conformity with the thorough knowledge of Roses which has always distinguished him as a great authority in all that relates to them. If the other growers who deem it necessary to insert new kinds before fully proved were to give them in a separate list, as is sometimes done, it would decidedly improve their catalogues.

All lovers of the Rose owe a tribute of respect to M. Verdier for the many charming varieties originated in his establishment. He has also readily acknowledged the merit of English horticulturists by conferring their names on flowers originated or sent out by him—names that are highly esteemed and respected among us, as will be seen by the list presently to be given.

M. Verdier's announcements are in two lists—the first, published in September, contains the new kinds originated in his own establishment and some others sent out by him (for the perusal of this I am indebted to the kindness of the Rev. W. F. Radcliffe, of Rushton); the second contains the kinds obtained from the seed-beds, and sent out for the first time by other French nurserymen. In these lists there are seventy-three Hybrid Perpetuals, seven Bourbons, two Teascented, three Perpetual Moss, two hybrids from Bourbon and Noisette, and one Microphylla—in all eighty-eight. These statistics are given that your readers unacquainted with the facts may judge for themselves of the enormous number of varieties yearly offered for our acceptance, and, of course, grievous disappointment if we are foolish enough to take the bait. Seeing, too, that the modest price of 25 francs—that is, £1—is asked for a single plant of very many of them, our French friends must evidently have fast hold of the notion that "John Bull has more money than wit." It is a sheer impossibility that all of these new Roses can be improvements upon those we already possess; it is even

doubtful at present whether any of them are. There is nothing to indicate it in the descriptions given of them, with one exception to be presently noticed. If, therefore, this annual influx is not steadily resisted by our great growers, with some reservation, their collections will continue to be disfigured by kinds not entitled to a place in them.

The following are selected from the list, with the descriptions given by the raisers. They are all of them stated to be of vigorous habit, with large and full flowers, and may probably in time be found to be of some merit. It is quite useless to entertain any expectation of sorts in our climate that have not a sound and hardy constitution. If any hope on the point may be expressed it is that the kind bearing the name of the worthy rector of Rushton may prove a sterling acquisition, it will then be a recognition of merit, reminding the Rose-loving public of a good and painstaking rosarian.

Docteur Andry (Verdier).—Perfectly imbricated; deep reddish carmine; flowers about 12 centimetres in diameter (4½ inches). A variety of the highest merit.

Rushton Radcliffe (Verdier).—Perfectly imbricated; fine cherry red, clear and distinct; from 10 to 12 centimetres in diameter (4 to 4½ inches).

Souvenir de William Wood (Verdier).—Blackish purple, very dark, similar to Prince Camille de Rohan, but darker; flowers from 9 to 10 centimetres in diameter (3½ to 4 inches).

John Keynes (sent out by Verdier, but not obtained from his seed-plots).—Vivid reddish scarlet, shaded maroon; 10 to 12 centimetres in diameter (4 to 4½ inches).

William Bull (sent out by Verdier).—Globular and well formed; bright cherry red; about 12 centimetres in diameter (4½ inches).

Charles Wood (Portemer, jun.).—Deep red, shaded blackish, of fine form; 9 to 10 centimetres in diameter (3½ to 4 inches).

Denis Helye (Gautereau).—Very erect; bright rosy carmine; 12 to 14 centimetres in diameter (4½ to 5½ inches). A very effective variety.

Madame Moreau (Gonod).—Cupped, paeony-shaped, with large petals at the circumference; bright dazzling red, shaded with violet; 12 to 14 centimetres in diameter (4½ to 5½ inches).

Charles Margottin (Margottin).—Brilliant carmine, with fiery centre.

Duc de Wellington (Granger).—Bright red, velvety, shaded black, with lighter centre.

John Veitch (Levèque).—Well formed; fine, vivid, shining red.

Madame Charles Verdier (Lacharme).—Well formed; fine vermillion rose, between Baron Prévost and Duchess of Sutherland.

Mademoiselle Loïde de Falloux (Trouillard).—Fine form; white, slightly tinged with rose.

Monsieur Boncenne (Liabaud).—Cupped; velvety, blackish-purple.

Xavier Olibo (Lacharme).—Fine form; velvety black, shaded fiery amaranth.

One of the most promising, should it prove sufficiently hardy, is the *Tea* or *Noisette*.

Maréchal Niel very vigorous, with long, stout, reddish branches; leaves consisting of three or five leaflets, extra large, shining and undulated; flowers full, from 12 to 14 centimetres in diameter (4½ to 5½ inches), of a beautiful deep yellow, intensely fragrant. Obtained some years ago by a horticulturist in the south of France, and it has till the present time remained unknown. This magnificent Rose is the most beautiful of all the Noisettes, to which belong Chromatella (Cloth of Gold), Isabella Gray, Jean Hardy, Solfaterre, &c., and surpasses them in habit and abundance of bloom. So says M. Verdier.

But if all the above are at present little known to us except by name and the raisers' descriptions, there are some by our own countrymen now being, or about to be, distributed which may be depended on, and, therefore, worth immediate attention. Such are *Princess of Wales* (W. Paul), *Dr. Lindley* (W. Paul), *King's Acre* (Cranston), *Beauty of Westerham* (Cattell), a fine autumnal Rose, fully described at page 312.—ADOLPHUS H. KENT, Blechingley.

PLACE AUX DAMES!—I have just been shocked to read, in the Rose catalogue of Messrs. William Wood & Son, that "Reynolds Hole, cupped and double, is in the way of Louise

Odier;" and as this can only mean that I, in a state of ineptitude, and in the position which schoolboys assume when giving each other a back at leapfrog, am obstructing a young lady's path, I think it my duty, as a married clergyman, immediately to assure your readers that I am perfectly sober, perfectly straight, and have never performed gymnastic contortions in the presence of Miss Louise Odier.

—REYNOLDS HOLE, H.P.

DOUBLE-GLAZED FRAMES FOR EXCLUDING COLD.

THERE are so many persons who desire to save their plants during winter, who have no means of applying heat in any way, that I think I may do them a service by bringing to their notice the plan I have found so very useful—viz., a double frame to keep out the extreme cold.

This idea I obtained from seeing double windows employed in several London houses, in Piccadilly, and the west of London generally, to keep out the noise, and maintain the rooms at a more equable temperature. Knowing well, as I do, that a stratum of air between two glasses will keep out noise, heat, and cold, the adaptation of this principle to preserving plants in winter is not very surprising, and having in practice for two or three years proved its value I now bring it before your readers in order to verify my discovery, or rather adaptation, of a fact well known.

I have had my lights made with a very broad frame, so that two sashes can be made upon it, one under, one over, so that they both lift at the same time, when it is necessary to give air to the plants beneath. I have some of the usual—shall I say old-fashioned?—glasses, the snow has fallen upon them, and I find a very marked difference in the melting of the snow. The snow rapidly disappears from the single lights, but on my double sashes it remains. I will not go into the science of radiation, conduction, transmission of heat, &c., suffice it to say to a gardener, that with a double light the cold will not go down to half-buried pots or plants as through a single light.—SEPTIMUS PIESSE, Ph.D., F.C.S., &c., Chiswick.

NOTES MADE IN THE ENVIRONS OF PARIS DURING A VISIT IN SEPTEMBER.

ABOUT five years ago you were pleased to insert in your pleasant and useful Journal, a few notes made by me during a visit which I had then paid to the Valley of Montmorency, celebrated for many horticultural productions—amongst fruit, Pears, Peaches, Grapes, Cherries; and amongst vegetables, notably Asparagus.

I have again paid a visit to that beautiful country, and I am not singular in my estimate of it, for since I was last there a vast number of country seats of more or less importance have sprung up, the Parisians having taken a lesson out of our book by residing in the environs, not, it is true, quite to the extent we do here, but leaving Paris for five or six months of the summer only. It takes a long time to reconcile ladies who have resided all their lives in so gay and so fascinating a capital as Paris, to satisfy themselves with the quietude and domesticity of a genuine country life. No opera! No theatres! No society even—at least not that varied and amusing one which they have been accustomed to. A country residence, therefore, during the winter months would be looked on as little less than an expatriation. In fact, until a radical reform takes place, it would be difficult for a family to carry out such a project, unless they made up their minds to do so in the most primitive style, and wait upon themselves; for one of my friends having made up his mind to give up his town house, coachman, footman, cook, lady's maid, and all the rest of the fry, waited upon the mistress to inform her that they must leave her service. "Why, what does all this mean? What is the matter that you should thus all wish to leave at the same moment?" "Well, Madame, we are very contented and very happy in your service, but we hear that it is your intention to remain in the country all the year round, and in the winter we should all die of *ennui*."

When it was told to me, I remarked at once, "Well, you let them all go of course." "Indeed, we did not, but, on the contrary, gave up our project, as we were quite certain that we should never be enabled to replace our old servants by others."

Time, however, works wonders, and in the course of a very few years I have no doubt we shall see families making the country their permanent residence, and this will produce a favourable effect by increasing the traffic on the railways, which, except by the morning and evening trains, is very small even during the summer months, as families residing for six or seven months of the year in Paris, have no desire to go there very frequently. Of course, I am alluding to the families of merchants and those engaged in commerce. Constant residence would also tend much to encourage horticulture, for although a vast deal of money is already expended in the pursuit, yet it is confined to those who may be strictly termed the rich. These have certainly very pretty and tolerably well-kept gardens, and, as a rule, very extensive ones, but they would be neater-looking, bear examining more minutely did their owners have them constantly under their eyes during the winter as well as summer months. Well-kept lawns would then be better appreciated, but I see no improvement in them since last there. The ladies, who take the initiative in all gardening matters, appear to understand the difference between an English and a French-kept lawn, but they are powerless over the obstinacy and stupidity of their gardeners. Talk to one of these latter about cutting the grass once a-week and he would simply think you mad. As to rolling and cutting edges, it is quite out of the question, and the iron roller continues to be unknown.

I am only referring to the private gardens. The public ones decidedly take the lead. In them every available implement is taken advantage of. I saw one which may be known here, but was quite new to me. It was a double roller, or rather a pair of rollers, one following another and worked by a locomotive. The rollers were, I should say, 4 feet in diameter and of great power. The grass-cutting machine I could not hear of either in Paris or its environs. What are Messrs. Green about? What Messrs. Shanks, that they do not make their machines known? They are wanted badly enough, for even in the public gardens the lawns do not come up to the standard of excellence required by the critical eye of an Englishman. In other respects these gardens are tastefully laid out and artistically arranged. The system of ribbon-beds and massing is not carried out to the exclusion of mixed borders, which I examined with minute attention. The harmony of colours was well observed, as was geometrical precision as to distances, and every border was a mass of either flowers or foliage, although there was nothing strikingly new to record. Clumps of Fuchsias hiding the stems of standard Roses, Gladioli serving the same purpose, Dahlias tied up as they grew so as to form a straight column, were stiff perhaps, but the blossoms were concentrated, none straggling about or hanging down.

I have said that the borders were a mass of flowers or foliage. This latter may not seem a desideratum to us; but French taste runs much on handsome-leaved plants of the tropical class, amongst which Cannas figure to a considerable extent. These are used both as single objects and in large masses without the admixture of any flowering plant, save, perhaps, an edging of some large Geranium—the Pink, much the same colour but larger than Christine, being a favourite. By-the-way, does Tom Thumb grow larger there than here? it so appeared to me. But to return to the mixed borders. Every plant is placed in a hollow, so that water may be given without fear of its running away from the roots. The system of watering, too, is good and uncommon. A series of Indian-rubber tubes is formed by screwing one into the other until the required length be arrived at. These tubes are perforated with very small holes, and care is taken that in screwing them on to each other, the holes form a continuous and straight line. The tubes are laid on the ground, alongside a border let us say, the cock is turned and a fine and gentle shower falls on everything within its reach. One man can thus regulate a long length of tubing, removing it from time to time as required. I saw this system in operation in the gardens of the Tuilleries and the Jardin d'Acclimation.

mataion. In the latter place I was caught in the shower when strolling off the public thoroughfares.

But I shall tire your readers by this discursive chat. I sat down with the intention of addressing you upon one subject, and I have not yet touched upon it. I mean

THE CULTURE OF ASPARAGUS.

It appears to me that we have yet much to learn of the cultivation of this much-esteemed vegetable. The noted grower in France, is Monsieur L'Héraut, of Argenteuil, the neighbourhood where I was visiting. He is, no doubt, known to many of our horticulturists, as he has been studying the growth of this vegetable for the last twenty years, and has carried off eighteen medals, three being enamel, one bronze, twelve silver, and two gold. One of these last was from the Brussels Show of this year, where, by the way, it was stated that with the exception of the Père L'Héraut, the French made themselves conspicuous by their absence.

Le Père L'Héraut for many years possessed but one hectare of land (a little less than $\frac{2}{3}$ acres), upon this he confined himself to the cultivation of Asparagus; but from it he derived an income of 4000f.—say, £160 per annum. He sells his produce to the first-class restaurants and purveyors of Paris at inconceivably high prices. He produces bundles containing thirty-five heads, measuring 14 inches long, and weighing 6 kilogrammes, or roughly 12 lbs., for which he receives from 25f. to 30f., and that during the entire season. The smaller heads sell at from 5f. to 10f. He has latterly been joined by his son, the firm being now L'Héraut, Salboeuf et fils, and they have added considerably to the extent of their land. On one piece I saw 2000 plants, on another 1700.

Argenteuil being only a few miles from the residence of my host, I drove over and saw both father and son. We happened to hit on the very first day of the vintage, every hand was in the fields, but we found Madame L'Héraut, the son's wife, and she with genuine French amiability insisted on conducting us to her husband. Leaving our carriage, therefore, with the groom we trudged through the vineyards, and a most animating sight it was. It was just the moment of the midday repast of bread and Grapes, and the various groups looked like so many pic-nic parties, everybody was very merry, for the groups were not composed merely of the labourers but of their friends also. All are welcome at such a time to eat their fill. A quarter of an hour's walk brought us to the vineyards of Père & fils L'Héraut. The first I found a plain unpretending gardener of the old school, with an idea about going a-head nevertheless; the son a fine specimen, physically, of a Frenchman. He had been a soldier, of course, had a good intelligent face, and we soon found him to be thoroughly up to his business. The father being occupied with looking after his people, the son ciceroned us, after dispatching to the wine press two carts laden with open barrels filled with Grapes of the morning's gathering. From him and from a pamphlet which he gave me, published by himself, and entitled "*Culture des Asperges en Plein Air*," and sold at 50 centimes, say 5d., I learnt the following:—

The Asparagus flourishes best on an old vineyard, as the copious nourishment given to the Vine suits it. The older a soil and the more worked it may have been, always provided that it has been constantly well kept up, the better.

The seed has much to do with success. At the commencement of their career they grew the Hardy Dutch, a very productive variety but not bigger than the middle finger, and having the disadvantage of producing its crop all at once. For many years past they have saved their own seed from some they originally had under the name of *Rose de Hollande Perfectionnée*. This variety is in quality and size much superior to that grown in the locality. It produces during a longer period, and gives first-rate and increasing crops up to the age of six or seven years, and will then continue good for another twenty years. For the raising of this seed and its cultivation I must refer your readers to the pamphlet in question. I must confine myself to the plant itself.

In the selection of the ground never take the site of an old Asparagus-bed. A soil slightly clayey suits the *Rose de Hollande* best; but this variety up to its sixth year is not an abundant producer, although it amply makes amends by its exceptional size and quality, by the longer duration of its season, and by the greater longevity of the plants.

A sandy and dry soil suits only the smaller varieties of Asparagus.

In making a plantation no beds are raised above the surface. Holes are dug on the level ground in the autumn 20 inches in diameter, and 6 inches deep, 1 yard apart, and 4 feet distance in the rows. The earth taken out is placed between the rows in the form of hillocks, which may be used for early Potatoes, Lettuces, or Dwarf Beans—anything in short that comes off early. Into each hole is thrown 3 inches deep of half-rotten stable manure mixed with cowdung and town rubbish, or in default of this last, road scrapings and rotted vegetable refuse—the older the better. It is covered to the depth of $1\frac{1}{2}$ inch with some of the earth taken from the holes.

In the month of March, towards the end in this country, the one-year-old plants are put in by opening a hole with the hand between the manure, one plant to each hole, taking care to spread out the roots carefully and equally; cover with $1\frac{1}{2}$ inch of the soil, pressing the extremities of the roots strongly down, place a stick to each to mark the spot that no injury may arise when digging the ground.

During the summer months keep the ground as free from weeds as a lady's flower garden. In the autumn when the stems are nearly dry, cut them down to the height of 6 inches. Should any have failed let the stick remain to indicate the spot, and replace in the following March. In the month of November the roots should be subjected to the action of the atmosphere by removing a little of the earth from the surface; and in this state the plant passes the winter, for it must be borne in mind, that Asparagus does not suffer from cold, but moisture, and the more earth there may be over the crown the greater will be the amount of such moisture.

The cultivation for the second year is the same, except that a little more soil may be thrown over the crown at the beginning of April, and a stake 4 feet long should be placed between every alternate plant, so that the two plants may be attached thereto, in the autumn, to prevent their being blown about or broken off by the wind, which is very injurious. The wind causes the stems to make holes at the base, into which the rain enters and rots the crown.

In the third season of their growth, about the middle of March, if warm, the ends of the stalks should be removed, and each plant should be earthed-up to the depth of 8 inches for the stronger, but less for the weaker. These mounds should be raised exactly over the centre of each crown. The largest heads may be taken during fifteen days only, and when about 2 inches high, as a rule we should be satisfied with taking from three-year-old plants two heads from each. You will observe that I do not use the word "cutting," but "taking" off. I must be permitted to tell a little story thereon. At a Meeting of the French Horticultural Society in Paris, various knives for cutting Asparagus were sent in by makers. The President, the Comte de Morny, said—"Well, gentlemen, I think we must leave it to the most experienced man in France on this subject, Monsieur Père L'Héraut, to decide on the merits of these;" but to the amazement of all present he stated that he knew no more about it than they did, for he never cut a head in his life, and should consider it murder to do so. Being called on to explain, he did so to the following effect:—

"The earth is removed until the two fingers arrive at the head of the crown, the stalk is then thrust off (much as we take off Rhubarb-stalks I presume). If, however, it will not come off without injury to the crown, a blunt knife is placed against it close to its junction with the latter, and it is snapped off by pressure. The crown is then earthed-up again. In the autumn all the earth is removed down to the crowns and replaced by the compost already alluded to, a little of the old, light, pulverised soil is thrown on again, and the ground between the rows is then well dug-down to the roots, taking care, however, not to injure them. In the March of the fourth year the earthing-up may be increased in height to 10 inches. More heads may now be taken from the plants and during a longer period. In the spring of the fifth year the soil may be earthed-up in one continuous line, and fresh compost put in the alleys in its place. This compost serves to walk upon, and is getting into condition for use in the following year. In the autumn the ground is again levelled, and this is continued from year to year. During the fifth year the gathering may continue for a

month ; and in the sixth year the plants are in perfection, and it may be carried on for six weeks ; but the season for this vegetable ought never to extend beyond that period, except by beginning earlier with forced plants."

It may interest some of your readers, particularly small gardeners, if I give my calculation of the profit derived from the growth of this vegetable by M. L'Héroux.

I have said that the produce of his £ s. d. £ s. d.
hectare of land brought him in 4000f.
a-year, which we will call 160 0 0

I cannot say what is paid for land in Argenteuil ; therefore, I will take it and labour at its worth here—say, then, for rent 22 0 0

With the exception of carting compost, the whole was cultivated by himself. I take his own labour then at 4s. a-day—a high rate here, quite unknown in France. That would be ... 63 0 0

Forty loads of compost and delivery at 10s. (Is it too much or too little?) 20 0 0
105 0 0

Nett profit £55 0 0

I have no doubt the profit is much larger in France, but an English gardener would not look with contempt at that, I think. I shall be glad to be set right on any of these points, and, in fact, court criticism. I see already that I have omitted one item—viz., the delivery of the Asparagus daily throughout the season. This expense must be deducted from what I have given as the nett profit.

I mean to try this system, and have ordered my few plants to be sent me at the fitting time, which will be in the month of March, and they will be one year old. M. L'Héroux will not recommend a plantation to be begun with older ones. He insists that nothing is gained by it.

If you think my annual progress would be at all interesting, I shall be happy to give you a few lines thereon this time next year.—H. S. WATSON, Old Charlton.

COMPARATIVE PROLIFICACY OF POTA OES

I SEND you the results of experiments made by myself in the produce of various sorts of Potatoes, which I can vouch for having had exactly the same sort of treatment in every way. They were grown in what we call black soil, which produces Potatoes largely, but not, perhaps, of so good quality as brown soil. I have, however, found them all to be good eaters. Paterson's Blue is a beautiful Potato in appearance, and of great size ; I had several Potatoes weighing 31, 30, 29, and 28 ozs. The Napoleon is a very rank-growing Potato, with haulms as thick as a strong walking-stick. It is a good eater, but from its great haulm must be an exhausting crop. The Fluke figures badly, possibly from a want of change of seed. My own experience would make me think that it does not crop so heavily as formerly in this neighbourhood. Nos. 1, 2, 3, 5, 6, 8, 9, 13, and 14, were all got from Scotland, from different places. I had no preference. I tried the experiments fairly.—W. W. H., Prescot, Lancashire.

Weight of Sets.	Sort.	Weight of Marketable Produce.
1.—14 lbs.	Paterson's Blue,	618 lbs., or 44 times the weight planted
2.—14 lbs.	Paterson's Regent	539 lbs., or 38 times ditto.
3.—14 lbs.	Paterson's Red	401 lbs., or 28½ times ditto.
4.—14 lbs.	Daintree's Early	394 lbs., or 28 times ditto.
5.—14 lbs.	Paterson's Oval Blue	359 lbs., or 25 times ditto.
6.—14 lbs.	Paterson's Victoria	329 lbs., or 23½ times ditto.
7.—14 lbs.	Webb's Imperial	272 lbs., or 19 times ditto.
8.—14 lbs.	Paterson's Napoleon	229 lbs., or 16 times ditto.
9.—14 lbs.	Dalmahoy	221 lbs., or not quite 16 times ditto.
10.—14 lbs.	Pink-eye, Kemp	200 lbs., or more than 12 times ditto.
11.—14 lbs.	Arrowsmith's Seedling	179 lbs., or 13 times ditto.
12.—14 lbs.	Fluke	95 lbs., or 7 times ditto.
13.—14 lbs.	Bloomer	92 lbs., or 6½ times ditto.
14.—8 lbs.	Rosse's Early	272 lbs., or 34 times ditto.

FLOWER FARMING.—Take a pair of compasses and strike an arc on the map of the French shores of the Mediterranean, making the Fort of Antibes the centre, open the compasses to Nice, and strike round—the highest point will be Grasse ; then descending again to the shore in an opposite

direction, the compass leg will mark the fringe of the Estrelle hills, and the well-known town of Cannes, with Lord Brougham's villa. From Nice to Cannes it is twenty miles, and from Grasse to the shore ten miles. The three towns form a geographical triangle, having the tideless blue sea for its base. Within this triangle is the valley of the Flower Farms. There are flower farms in England also, but they are insignificant in comparison with those of France. Elsewhere flowers are ornaments—charming accidents. Here they are staples. They grow like grass and corn, like Potatoes and Mangold Wurtzel. Here bloom the Jasmine, the Orange, the Violet, the Tuberose, the Jonquil, the Rose, the Cassia, not as in our beds, not as in horticultural gardens, not as gardens, but as fields. Broad acres of colour flash under the hot sun. The atmosphere is heavy with perfumes when the snows are melting on the mountains, and the gurgling Var is rapidly growing into a roaring torrent. Here we enter homesteads not of golden grain, but of Lavender sheaves; not of cheese, but of olive oil; not of beer and elder wine, but of orange-flower and rose-water in vats; not of clotted cream, but of jasmine and violet butter. It is like a country of the "Arabian Nights." You expect the dark-eyed peasants to answer you in lyrics, and the very dogs to bark in tropes. You are oppressed with the prodigality of splendour. The soil is so fertile that, to borrow Douglas Jerrold's witty conceit, if you tickle it with a hoe, it smiles with a flower; or, as the natives say, if you plant a walking-stick, the ferule will blossom.—DR. SEPTIMUS PIESSE, in the *Cornhill Magazine*.

CHOICE PEARS.

I SEE that the Rev. S. R. Hole has recommended a Pear. I will venture to recommend a first-rate one, Beurré Superfin. I tested it by my Marie Louise, which is also a first-rate Pear, but not quite so good as Beurré Superfin. I tasted also at the same time Marie Louise d'Acce. It is delicious, very handsome, and of a beautiful colour, golden russet. In July I tasted Doyenné d'Eté, a good cropper, and nice for an early Pear. Beurré Mauxion, and Comte de Lamy, are good croppers, and very good.

Mr. Rivers made me a present of twenty Pear trees on the quince stock, and they were planted on the 25th of March and 9th of April this year. I am quite pleased with the little trees and their fruits. Two had no blooms, and one, Madame Millet, dropped its fruit. The others I have not tasted, as they are late Pears.

Doyenné d'Alençon is a fine Pear; Duchesse d'Angoulême is very fine, three Pears not yet ripe weighed 25 ozs.; Beurré Beaumont bore fourteen handsome Pears, and is the healthiest-looking tree of them all; Beurré Diel is very fine.

The little trees, several of which bore fourteen Pears, have much pleased both me and my visitors. I shall move every plant yearly, and put some decayed dung and mould under them, and I do not expect to report, as some have done, a failure with Pears on the quince stock. I recommend people to procure Mr. Rivers' twelfth edition of the "Miniatue Fruit Garden."

As I am on pomology, I may mention that when I had the pleasure of dining with Dr. Hogg, I tasted some excellent Grapes from Mr. Rivers. I have forgotten the names of all but one, and that was first-rate, the Early Smyrna Frontignan.—W. F. RADCLYFFE, Rushton.

GARDEN REQUIREMENTS FOR NEW ZEALAND.

REPLYING in part to the inquiries of your correspondent, "J. C.," in your paper of the 25th, we beg to say we send out monthly considerable quantities of grass and other agricultural as well as garden seeds to New Zealand, and we gather from this that settlers there do not grow their own seeds, which is confirmed by a gentleman to whom we annually send large quantities coming to England this year and ordering a still larger supply. We should recommend your correspondent to take out tools with him, he would be sure to get what he wanted here, which he might not be able to do in New Zealand. With regard to plants of Strawberries,

and Quicks, we do not know whether they would undergo such a journey, but a "fruit nurseryman" would, doubtless, know. If they are taken they should be packed separately. Seeds for New Zealand should be packed in stout wooden cases lined with zinc, which are of no small value over there.

—SUTTON & SONS, Reading.

I AM able to answer "J. C." having spent fifteen years in that country. I have seen Strawberry plants taken out in a small Wardian case, but "J. C." need not go to that trouble unless he has some very extraordinary sorts. He will find plenty of Strawberries in New Zealand.

Tools are to be had at all the chief towns. However, he might take a light spade with extra bindings on the handle, and a small four-pronged Potato-fork. He would also find a light single-edged billhook handy. Quick thrives well in stiff clay soils, but in the light soils of New Zealand it fails, and Furze is grown in its place. Quick does well in Nelson, and in some parts of Auckland. In Taranaki all the hedges are of Furze. Grass seed is grown extensively in New Zealand, but a little good Perennial Rye Grass would always find a market. Red Clover does not seed there, consequently that may be taken; but the colonists look with suspicion on English seed, it is so often spoilt on the passage. Seeds of the Brassicas are more often good than any other. "J. C." may take Cabbage, Cauliflower, Radish, and similar seeds, and will find a market for them, as the colonists find a difficulty in producing seeds of this family in a pure state.

English-grown Onion seed always fails. "J. C." will find the American blight very destructive to the Apple trees. If he can take out a remedy he will do some service. A fungus is very destructive to the roots of exotic trees. High winds are rather troublesome. With these exceptions he will find New Zealand a fine country. He must make up his mind for hard work; for gentlemen gardeners are very rare in that country. With industry, sobriety, and perseverance success is certain.

"J. C." must not put his seeds in the ship's hold, but must keep them in a box in his cabin. The damp heat of the hold in the Tropics destroys their vitality.—BENJ. WELLS, 11, Orchard Place, Plumstead Road, Woolwich.

ENVILLE HALL.

THIS magnificent demesne of the Earl of Stamford and Warrington, is situated about six miles from the thriving, busy town of Stourbridge, which itself is nearly a mile from the railway station. The traveller who goes from and returns to Birmingham, will require a fair stock of patience, amidst the waitings and changings at Dudley and Dudley Port junctions, &c. On leaving the west side of Stourbridge we noticed a neat, handsome church, school houses, residence for teachers, and at a short distance a residence for the clergyman, all erected and presented by William Foster, Esq., M.P., to the inhabitants of Stourbridge. Ere long we notice in a hollow on the right hand the homestead of the above benevolent gentleman, Stourton Castle, celebrated as the birthplace of Cardinal Pole, and for the attempted batterings it received from the cannon of Cromwell, placed on the towering peak of Kinver Edge. Many and somewhat contradictory are the traditions amongst the people, as to the success or failure of the cannonading. Kinver Edge itself, with its frowning peak becomes a fine feature in the landscape. As we mount the high crests of the road, we get fine views of the beautifully wooded, undulated hills that, mingled with large intervening breadths of sheep-walks, form the back grounds of Envile. As we have stood on the Hoe at Plymouth, and admired the rich verdure of the woods of Mount Edgecumbe, we have felt that the bald waste that crested the hill, detracted from the richness of the luxuriance that skirted the shores. There is nothing of this at Envile, as we approach it, because the rich pasture lands that on these elevated plateaus diversify the landscape, are themselves bounded by luxuriant woods, forming the sky outline.

Ere long passing the old kitchen garden, still used for growing vegetables, and through part of the race course, a large waste covered with heather and fine masses of sombre bonnet-headed Scotch Firs, we reach the village, and in-

stead of going north-westward some ten miles to Bridge-north, or right forward into a splendid hotel, just now built, chiefly for the accommodation of visitors, we turn into a private road on the left, pass the north end of the kitchen garden, and the finest cricket ground in England, of six acres in extent, level throughout, and beautifully kept, on one side of the road, and on the other side, after passing Mr. Craw's house, the post office, several private, and one public entrance to the pleasure grounds, we arrive at the mansion, a substantial, commodious structure, and as we were informed, most beautifully furnished, and elegantly decorated within; but in its low level position, and external plainness, forming a striking contrast with the vast and the magnificent around it.

Now, where shall we begin to give our readers some idea of the impressions left on us from our hasty visit to this interesting place? After a little consideration, we think it will be best first to look through the kitchen and fruit garden, because after all these are the concerns of the greatest utility; and, secondly, because in the much that we have heard about flower-beds and shrubbery, we have heard but little as to the kitchen garden, and the means for keeping up a supply in all departments.

The new kitchen garden, in contradistinction to the old one, is about twelve acres in extent, and about five of these are inside the substantial walls. The vegetables seemed to have suffered but little from the drought we experienced farther south, partly, no doubt, owing to the abundance of the water supply. The great proportion of the trees against the walls had been lifted the previous season and replanted, after placing a quantity of good turf soil beneath each tree. Espaliers and dwarf standards by the sides of walks had been treated in the same way, and with the best results. Large quarters were in course of preparation for Strawberry planting, and in several open spaces between pits and houses, where unobstructed sunlight could be obtained, were some four thousand pots of Strawberries for forcing, mostly in six and seven-inch pots, very strong, and ripening their buds well. There were some Black Prince and Keens' for early work, and Queens for late produce, but the great bulk of the plants were Sir Charles Napier and Oscar, and of these latter Mr. Craw spoke highly for quality and produce. Outside, besides many flowering plants to be forced, we noticed a great quantity of compact plants studded with flower-buds of the Azalea amceana, which Mr. Craw stated forced beautifully.

To insure something like variety, we shall now take a walk through the different structures, beginning at the north side of the garden.

Outside of the walls, besides soil, composts, &c., neatly kept, carpenter's workshop, pot bins, &c., is a cucumber-house, 60 feet long, 11 feet wide, and 9 feet to the apex, with a short hip from the back wall, and 3 feet in front, walk along the back, bed heated below in front, ventilation at top by raising a short sash on south side by a lever. In front of these were two pits, glass covered, for various purposes, each 60 feet in length, and two open brick pits, filled with Roses and other things for forcing, and a great number of *Lilium giganteum*, ripening their large crowns, the older leaves hanging in a drooping, withering condition over the sides of the large pots. Most of these had been grown from sucker offsets. Several plants that had bloomed showed the mark of the thick stems they had produced. Such plants must make a grand appearance in the large conservatory. Rich treatment, and huge bushel pots, seemed to be the secret of their successful cultivation, along with the ripening and resting process given to them in the autumn.

These low, open brick-pits are a mark in the right direction, as showing a certain amount of care and protection given to the plants placed in them, and doing away with the want of order and neatness, which is apt to prevail when plants in pots stand here, there, and everywhere.

We next come to the principal range of lean-to forcing-houses, backed by their appropriate open and close sheds, for keeping composts and potting, stokeholes, &c. At present there are a number of furnaces, but it is intended ultimately to heat the whole by means of three boilers, unite the flues from these into one below ground, and raise a chimney for them among a dense mass of trees, so that the garden shall

be free from smoke. One of these boilers, a tubular one by Mr. Gray, has already been put down, with a merely temporary chimney, and Mr. Craw spoke very highly of the manner in which it did a great amount of work very efficiently.

In these back sheds there was one feature well worthy of note. In a corner was a small open boiler like a wash-house one, steaming away with manure water. This simple appendage furnishes at all times two great advantages. The operator is enabled to give water to his plants of the desirable temperature, and then whatever the manure used, be it horse, cow, sheep, deer, or other droppings, liquid manure from the farm, &c., boiling the water and material before diluting it prevents the possibility of the eggs of insects being thus communicated to the soil.

We turn in to the front of these sheds, and commencing at the east end we enter an early viney 40 feet long, 14 feet wide, 14 feet in height at back, and 3 feet in front. The Vines were pruned and cleaned, planted inside on a raised border, with arches in the front wall, and heated by pipes below in a chamber covered with stout slate, on which some rubble and then the soil were placed. The pipes were close to the front and the back wall, a small ledgewall bounding the path from the bed, and the Vines were planted inside of the front pipes. This seemed a very excellent house.

Next we come to two narrow late Fig-houses, with upright front glass, in the Trentham style, with Figs against the back wall, and a trellis stage in front for Strawberries, and other plants, the platform being sufficiently low not to shade the Figs on the back wall. In our younger days it was thought advisable to cover shaded back walls with Figs, because they would grow there, and so they would, but would they continue to yield fruit?

We now come to the Black Hamburg-house, where the wood was ripening nicely, the Vines planted also in a raised bed, but not heated below; and next we pass through a Muscat-house looking well. Then we enter a mixed house of Hamburgs, Lady Downes', and Buckland Sweetwater, the latter very fine. It is intended to make this house into a late one, by taking strong canes of Lady Downes' along the front of the house, and inarching these on the other Vines, especially the Hamburgs.

We then pass into a West's St. Peter's-house, but as his lordship is very partial to the Muscat Hamburg, it is proposed either to remove the West's St. Peter's, and plant with the desired kind, or inarch the Muscats on the present stocks, the choosing which must depend chiefly on the state of the present border. We then go through two narrow Fig-houses that have yielded their crop, the trees showing fine, short, stubby wood, and enter a viney with raised bed inside, planted this summer, outside border still to make as needed, and the Vines doing well—border on raised platform with hot-water pipes below to be used when needed, and some White Frontignans planted against the back wall, to be kept in bearing until the front Vines fill the house. The Vines in front are planted twice as thickly as they are intended to remain, for every alternate cane will be cut down and treated to secure strength for permanent cropping. The other Vines will be cropped until the permanent ones are fully established, and will then be cut out, and the house given up to the latter.

Our recollection of the rest of the village of houses and pits is more confused, as lean-to's, hipped-roofed, and span-roofed houses are more mingled. We will instance the following, beginning at the west end and going eastward. First, a large span-roofed Orchid-house, with two divisions, one for species from a cooler climate, and another for those from warmer latitudes. In the former, were many fine Caladiums, and fine-foliaged plants, and huge masses of Phaius grandifolius, the Bletia Tankervilleæ of our young days, which from the round full appearance of the large bulb-like crowns told of the brilliancy they would present with their spikes of flowers in winter and spring. In the warmer division, Nymphaea caerulea, and others, were blooming freely in a tank in the centre bed, scenting the house with their rich perfume. On the bed were several fine plants of the Peristeria elata (the Dove Plant) in bloom. In baskets suspended from the roof were huge masses of Dendrobium moschatum, latifolium, and Pierardi, whilst every open space was draped with pendant shoots of the rich-foliaged Cissus discolor. One of the distinctive features of this house, however, was a sort of

wide tank-shelf along the front and ends of the house, formed of slate, with an iron ledge screwed on so as to be water-tight. Here all the more valuable and more tender plants were situated, raised as deemed necessary above the water on the shelf. There is a tap at one end for draining the water off when deemed necessary, and replacing with fresh. The water not only keeps a moist atmosphere about the plants, but prevents most sorts of insects from getting either on the plants, or among the soil or sphagnum in which they grow.

Leaving these we enter a span-roofed house, 14 feet wide; height to apex, 9 feet; height in front, 4 feet, with pathway down the middle, and a raised bed on each side, heated below, and also heated above, and now filled with the best Tea Roses in pots, to yield flowers all the winter and spring—ventilation by moving short sashes by a lever on the south side of the ridge. Next we pass a large pit filled with cuttings of Geraniums in boxes—the cuttings small, showing that Mr. Craw was anxious not to spoil the outline of his beds—and come to a large hipped-roofed house, with raised bed in the centre, heated beneath, and pipes, exposed at sides, back and front, for forcing all sorts of things for the large conservatory. This house had a large cistern at one end, with hot-water pipes passing through it, so as always to secure plenty of hot water for use. Then we come to a large Pine pit of the old-fashioned kind, with a raised platform outside against the back wall for walking along, moving the sashes, &c. The Pines were very strong, and showing and swelling handsome fruit of Queens, Providences, &c. Then at right angles stands a span-roofed New Holland house, from 50 to 60 feet long, and 24 feet in width, and containing many fine specimens. Again: in different ranges, we have a Geranium-house, 50 feet long, with a curvilinear hipped-roofed on the north side, a sloping roof in front, a walk in the middle, and a bed of earth on each side, and used chiefly for forcing kinds; then a propagating-house, much in the style of the Rose-house, 11 feet wide, 8 feet high to ridge, 4 feet at sides, ventilation at top between double ridge-board, path down the centre, bed on each side, and each heated by pipes beneath the bed; and again we find a hipped span-roofed house for early Muscats, length 27 feet, height to apex 15 feet, height in front 3½ feet, width 18 feet, with soil-bed supported on arches, and heated below as well as above. The Vines were looking well, and had been planted nearly two years.

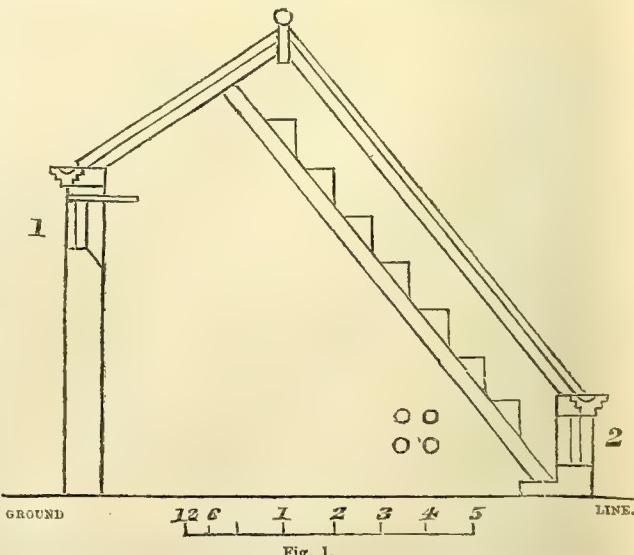

Fig. 1.

Many of these houses seemed so particularly suitable for the purpose contemplated, that we would have given sections of some of them, but for taking up room, and also because we think that from the dimensions given these sections may be made for themselves by any desirous of having them. We cannot help, however, giving the sections of two houses which seemed particularly well suited for the object aimed at.

The first is a Strawberry-house (*fig. 1*), 45½ feet in length, between 9 and 10 feet in width, inside measure, height to apex 10 feet, height in front 3 feet. 1 and 2 are wooden ventilators at back and front, hung by pivots in the centre. The diagonal pieces of wood supporting the shelves are as far apart as such supports for stages generally are, so that there is ample room for getting at these seven shelves easily from the inside of the house. It will be observed that all these shelves are at an equal distance from the glass, and that the slope of the glass is such as to give the greatest

amount of the direct rays of the sun to the plants beneath it during the early months of the year, when forced Strawberries are most in demand. We could well believe the statement of the wonderful crops obtained in this house, and from such plants in pots as we noticed ripening their crowns. We have seen no other house so suitable for the object, and can well imagine it would be free from the annoyances and insects that are apt to seize on the Strawberry when the plants are crowded into any and every open space in any house where there is heat. All who have the am-

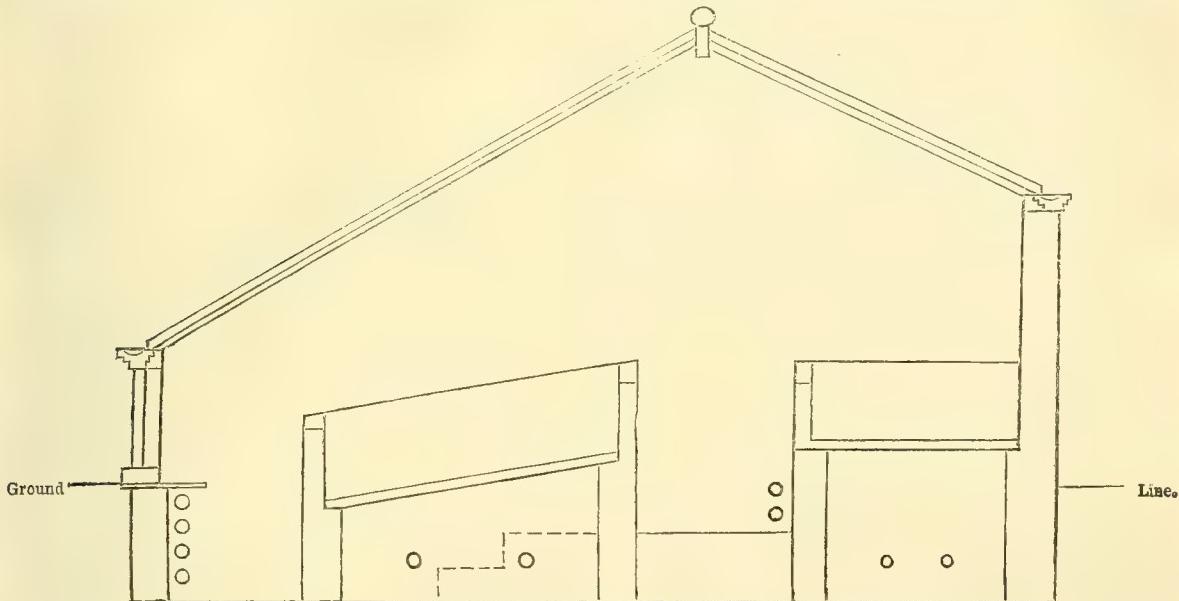

Fig. 2.

bition to keep everything and every structure to its right use, will thank us for this section of the Strawberry-house at Envile.

The other house is the principal Pine-stove, a cross section of which on the same scale as the preceding is given in *fig. 2*. The length of this house is 50 feet; width inside, 17 feet; height to apex from path, 10 feet; height in front above ground level, nearly 3 feet. The central path is sunk about 1 foot below the ground level, the front path 3 feet. There is a narrow bed at back, a wider bed in the middle, and a broad slate shelf above the hot-water pipes in front, forming a most valuable position for Dwarf Kidney Beans in winter. The beds are separately heated by hot water in a chamber beneath them, the top of the chamber being covered by strong slate. In this and other Pine-beds wood had been used for covering the chamber, with openings to let up the heat; but when the plants were

No doubt slate is much the best every way when the first expense can be comfortably incurred. The plants in these beds were all turned out into rough fibry soil, and showed by their stubby sturdy habit and the dark green of their foliage that they were receiving the treatment they required. Whilst passing through, the beds were being watered with rich manure water, nicely heated, that came from the open boiler to which we have already adverted; and the rough openness of the soil and perfect drainage would enable such enriching water to be given oftener, not only with impunity but with great advantage to the plants.

In front of all these houses, again, were three ranges of pits, each 170 feet in length—the first called the Melon range; the second used for propagating and keeping bedding plants, &c.; and a third, a low range without glass, formed of brick ends and sides, and a four-inch wall from back to front every 4 feet apart. This cross wall not only acts as a support to any cloth covering that may be used, but divides the whole length into so many separate divisions—a good plan for keeping each sort of plant placed there separate and distinct from its neighbour. On unrolling the frigido domo cloth on the morning of our visit to let the bright sun in, we found the whole of these open pits filled with Cloth of Gold, Golden Chain, Alma, Earl of Stamford, Little David, Pearl, and other Geraniums. The cuttings, having been pricked out into nice sandy soil, were rooting nicely, and would be raised and potted and kept in any place where room could be had during the winter. The sight of these pits without glass and with glass began to give us an idea whence would come the more than 100,000 plants that last season were used for planting in the pleasure grounds.

After admiring some Calceolarias in the borders, as Prince of Hesse (a fine deep crimson), Magnificent (a good brown), Tom Thumb, and some others raised by Mr. Watson, of St. Albans, we reached the south front of the middle wall of the garden. This wall is fronted with a beautiful, upright case, after the Trentham style, for Peaches, as only a part of the east end is devoted to Cherries, looking as if they would produce heavily. This case (see *fig. 3*) is altogether 360 feet

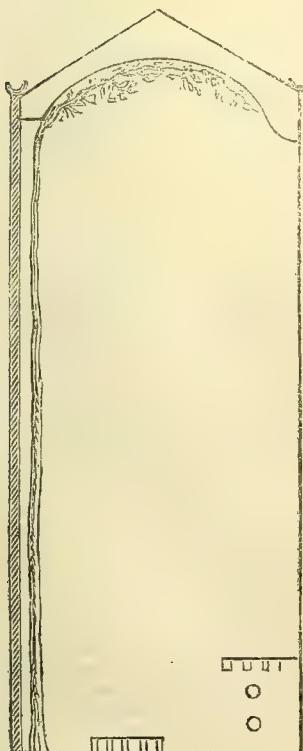

Fig. 3.

turned out, there was ever and anon the bother of a piece of wood giving way and letting a part of the bed down.

in length, $5\frac{1}{2}$ feet in width, back wall 14 feet in height, front glass the same height; height to apex of span-roof from ground, 16 feet. Every 20 feet along the back wall is a neat trellis about a foot in width, and which is continued in an arch over the pathway, from wall to glass, for growing on, and fastening to it Tea Roses, which are great favourites of his lordship, and many of which were beautifully in bloom in the beginning of October. Instead of the upright trees in front, as at Trentham, there is a latticed stage or shelf over the pipes, which Mr. Craw considers much preferable, as giving unobstructed light to the back wall, whilst these shelves are admirable places for fruiting great quantities of Strawberries in pots, and for keeping lots of other things in pots that are low in growth. The great height gives these cases an imposing appearance, and the whole is well finished; the large lights slide freely past each other, a stout plate of iron forming the ground sill all the way. The trees seemed in excellent condition. Part of the hipped-roof is opened for ventilation by lever power.

The west wall, or what we may call such for convenience, is covered with young, thriving trees of Apricots and Peaches, and the border is fronted with a broad gravel walk, at each end of which it is proposed to erect a summer-house, from which fine views may be obtained southward over the picturesque race course, and westward over the cricket ground, which must have a striking effect on a playing day, when enlivened by numbers of showy tents, flags and banners of all colours, plenty of music, and thousands of people criticising the sport, and so far making each splendid hit and run their own.

Part of the ground between this walk and the cricket ground is devoted to an orchard, and on the north side of it is placed the old conservatory, which was not considered good enough to grace the pleasure grounds. It is, however, a beautiful low structure, with ridge-and-furrow-roof, 140 ft. long, and 24 feet in width, divided into five or six houses, and heated to suit either stove or greenhouse plants. In it we found nice young plants of Camellias, Oranges, &c., and in one house a great many nice plants of *Hunaea elegans*, of which a great number is wanted every season. In the same house was also a number of very large pots, some 18 inches in diameter, with the different *Tropaeolums*, as tricolorum, *Jarrattii*, &c., growing in them. Several tubers were placed in each pot, this being about three parts full with soil, and as the shoots grew the earthing-up to the surface would be given gradually. Most of these would have the top of a young tree fastened in the pot, over which the branches would wind and clamber, and thus become fine objects for the large conservatory.

Next the gravel in front of this conservatory is an oblong square, devoted now to beds of flowers, but next season this space will be occupied by a geometric flower garden; and backed as it will be from the orchard by a hedge of Box, it will, we have no doubt, form a striking feature in these gardens, and the more especially as, notwithstanding the quantities of flowering plants used, there is nothing as yet of the regular or geometric in the vast pleasure grounds. Mr. Craw kindly showed us a plan of this new regular garden coloured, &c., and we have no doubt it will be a gem. It consists of a centre and a wing on each side in the broken chain style. The centre alone would make a neat garden, and as such we believe was sent some years ago by Mr. Craw from Ayrshire to the Horticultural Journal. We have, as far as we recollect, a promise that it will be again given in its extended form with the planting, and our readers will then judge if we have said more than sufficient of its elegance and its fitness for the position.

At the back of this conservatory three elegant rooms have been erected; the central one to be used by the family and friends as a resting and retiring-room when visiting the kitchen gardens, and the rooms on each side to be used as fruit-rooms. The walls are built hollow, air admitted at the bottom of the walls and in the roof; roof either double, or the ceiling well covered above with sawdust. The elegant windows and shelves for fruit are stained wainscot colour. The windows are furnished with blinds and shutters, to be used according to the weather. The shelves on three sides of the room are fitted up with slits of wood some $2\frac{1}{2}$ inches wide, with half-inch openings between, and the outside ledge is about $2\frac{1}{2}$ inches high. A table with drawers is yet to be placed in the centre of each room; and we will say no more

of them now, as we have the promise that a plan, with accompanying details, will be sent when all is finished. But there is one little thing we must notice, but which only seems little after we have seen it in operation, and so simple is it and useful that the wonder is that it has not been generally adopted long ago; so true is it that everything seems simple when it is understood and practised. The simple unique contrivance is this: Along each of these outside ledges a small strained galvanised wire is fixed, and opposite every kind of fruit the name is clearly written on a card label, which is then tied by a thread to the wire. As the fruit is changed the label is changed. This is far superior to laying labels on the fruit, or tacking them on the sides, and thus disfiguring them.—R. FISH.

(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

If any esculent roots remain in the ground they should be taken up immediately. Dress Asparagus-beds; manure, ridge, and trench all vacant ground, first making arrangements as to what spring crops it is intended for. *Cabbage*, earth-up those planted for Coleworts for winter and early spring use. Look over the principal plantations frequently to see if the slugs attack the plants. If they are numerous lay a quantity of Cabbage leaves on the ground and examine these daily. A pail of hot water or some lime may be taken round at the time they are examined, and the slugs shaken into it. By this simple method many thousands may be destroyed at this time of year. *Cauliflower*, lose no time in taking up those nearly fit for use, lay them in a frame, so as not to touch each other, and keep them free from dead and decaying leaves. *Celery*, earth-up that intended for winter use to a good height as soon as the soil becomes a little dry. It will be necessary to attend to this as early as an opportunity offers, as the frost may set in shortly, which, from the weather preventing earthing-up lately will do it much mischief. *Endive*, continue to blanch it by tying up or wrapping the leaves together and laying two flat tiles on each plant, so as to form a slight ridge, one tile overlapping the other. *Lettuces*, pay the same attention to the autumn plantations that was recommended for the Cabbages. Give air freely to the young plants in frames. The Cabbage Lettuces in frames for winter use will not require much air. *Peas*, a few, and also Broad Beans, may be sown on a dry, warm border. Some cover them with cinder ashes, but we have several times seen them go off in the spring, and have been fully satisfied that the ashes were the cause of their doing so.

FRUIT GARDEN.

Let there be no lack of attention in the fruit-room at present, for fruit requires more care during the first few weeks after gathering, than all the season afterwards. Give just sufficient air to carry off damp, but nothing more, as allowing dry winds to blow over the fruit would only cause shrivelling. Strawberries for early forcing should be placed where they can be protected from drenching rains, a cold frame or pit, where either can be spared, would be the best situation for them, but the lights should not be put on except in case of rain or frost. Indeed, the whole stock in pots for forcing would be benefited by being placed where it could be guarded from heavy rains. If any transplanting or root-pruning of fruit trees has to be done, let this be attended to as soon as the leaves are off, and see that trees exposed are securely staked before leaving them. Also, prepare the ground for fresh plantations, and plant the trees as soon as convenient. Take every opportunity of pushing forward pruning and nailing.

FLOWER GARDEN.

Those who propose making additions to their collection of Roses, should do so at once, as there will be a better chance of obtaining good plants now than after the nursery stock has been repeatedly picked. The present season is also very favourable for planting all but tender sorts, which had better be kept under glass until next May; but these should be procured at once, and if they can be placed in a gentle heat through the winter, they will grow freely and furnish cuttings which will root just as freely as Verbenas. In pre-

paring ground for Roses let it be trenched at least 2 feet deep, and well incorporate a very heavy dressing of manure with the soil to the full depth. It is hardly possible to make the soil too rich for any kind of Rose, particularly the autumn-blooming kinds, and 4 or 6 inches of good rotten farmyard dung will not be too much where the soil is naturally poor and light. Large-headed standards that have done blooming for the season should be cut back pretty freely to lessen the chance of their being injured by heavy gales of wind. Continue to clear the beds of their summer occupants as these become unsightly, and after trenching or doing whatever can be done to save time at next planting-out season, get them furnished for the spring. Look over the herbaceous-borders and make any projected alterations there, taking up and dividing any of the coarse-growing plants that may be inclined to encroach too much upon their neighbours. Roll and cleanse lawns from worm-casts; lime water may be employed to destroy worms if too numerous. Transplant Sweet Williams and single Wallflowers into beds or borders, to replace the gay but tender beauties which fade on the approach of winter. Plant bulbs and examine those previously set. Mice are particularly prone to destroy them.

GREENHOUSE AND CONSERVATORY.

Take advantage of unfavourable weather for outdoor-work to get the foliage of Camellias, Orange trees, &c., thoroughly cleaned, for it is hardly less essential to the health of such things that their foliage be kept clean and in a fit state to perform its functions, than that their roots be kept in a healthy active condition. Look over the plants frequently, and examine those liable to suffer from mildew and damp, such as Leschenaultias, Boronias, &c., for a short neglect will sometimes result in the disfigurement of a promising plant. The Boronias, Leschenaultias, Gompholobiums, &c., are very impatient of exposure to cold drying winds. Keep Cinerarias and other softwooded stock clear of green fly, and endeavour to secure stocky plants by affording them sufficient pot room, and admitting air freely whenever the weather permits. Cinerarias are rather liable to be attacked by mildew at this season, and if this enemy makes its appearance apply sulphur immediately it is perceived. In most places Chrysanthemums will be the chief feature of attraction at present, and where these are largely grown they make a fine display, and are worthy of every necessary attention to preserve them in beauty as long as possible. They are very impatient of a close rather warm atmosphere, and if the house contains plants requiring this treatment the Chrysanthemums should, as far as practicable, be placed in the coolest part, where air can be given freely at every favourable opportunity; for, unless they can be rather freely exposed to air, their foliage is soon attacked and disfigured by mildew, especially if the plants are bushy and well grown.

PITS AND FRAMES.

All flower-garden plants, such as Petunias, Verbenas, Calceolarias, &c., intended to be wintered in cold frames or pits should now have strict attention. Let their supply of water be limited to that quantity only which is requisite to keep them from flagging, and let them be frequently gone over, and all dead or decaying leaves immediately removed. Give them all the air possible during the day, if dry, and shut up tolerably early in the afternoon. Finish potting Dutch bulbs. Pot Rhododendrons, hardy Azaleas, Kalmias, Lily of the Valley, and all other plants usually required for winter forcing.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

On Saturday and Sunday week we caught the leavings of the storm that produced such havoc in Yorkshire and elsewhere. On Thursday last we had a day of almost continuous rain, which will do much good. Before it came we managed to earth-up the most of our Celery, among which, notwithstanding the drought, we have not yet seen a run head, thanks to our shading with evergreen boughs when we could give no water.

Notwithstanding our hoeing, we find the mild dripping weather is causing numbers of small weeds to show themselves among Spinach, young Onions, Cabbages, &c., and

the first dry day will be chosen to run the Dutch hoe among these crops again. It is wonderful how soon weeds come, even after great care has been taken to keep them away, and prevent any ripening their seeds. Well might some otherwise clever people adopt the theory of spontaneous generation, not only as respects these little weeds, but also as respects insects and other vermin, so annoying to the gardener. We believe that a single brown beetle, such as those that annoyed us last year, left alone during the winter, or any of its eggs untouched, would, by oval and viviparous generations, have millions of progeny before the end of the summer. We just as firmly believe if a fine plant of Chickweed, or of Groundsel, be allowed to ripen and scatter its seeds, and these seeds be turned down into the earth, so great is the vitality of the seeds, that enough of them may be brought within the vivifying influences of the atmosphere at every turning up of the soil, to give employment in hoe and hand-weeding for more than a generation of men. In our own case we ascribe the frequency of these weeds, notwithstanding the attempts to keep them from seeding, to the necessity of using anything we can procure from the sides of a small part of the highway, using leaf mould as almost our only manure, and raking the leaves where there is a likelihood of often having a fair allowance of seed weeds. Annual weeds alone will ever prevent the occupation of a gardener being a sinecure.

For vegetables in general, see previous weeks, if the weather will permit of the operations being performed. There have been few attacks on young Cabbages and Cauliflowers by grubs since we scattered a little tar on the surface of the ground, and watered them from a pool the sides of which we had plastered with tar; this, therefore, so far tainted the rain water that subsequently fell, but not so much as to do any harm to such plants out of doors. Gathered seed of Asparagus for sowing, then cut down the heads with an old scythe, and will clean and dress the ground as soon as possible. We always believe that this vegetable delights in rich treatment in summer when growing, more than when it is comparatively dormant in winter. Looked over Potatoes, Carrots, Onions, &c., and placed some of the winter Onions in the ground in a sheltered place to supply Scallions in hard weather in winter, and in an emergency to be stripped small for salading.

FRUIT GARDEN.

Here we did little else than protect Strawberries in pots from heavy rains. Took advantage of the muggy, drizzling weather to smoke Peach-house, early viney, and orchard-house, with bruised Laurel leaves, and a lot of tops of green Capsicums, chiefly as a measure of prevention. A solitary fly or two were discovered before the smoking, but they were dried up to mummies the next morning. We might have liked the tobacco smoke better, reaching into every cranny, of stem and wall; but then to produce and keep such a dense cloud in large houses for some eighteen hours, would have cost much, whilst the laurel-leaves cost nothing but the bruising. Care was taken that no flame should appear, and we have observed no green leaf suffer, though in some places the fumes had been so strong as to form a dark prussiate of lead on the painted rafters. It is of no use to attempt to wash off that dark colour, but left to itself, and with air on the house, it will gradually become of the original colour. Advantage was taken of the wet to shift a few fruit trees in small pots into larger ones, and to top-dress others after picking out some 1 or 2 inches of surface soil. If we could, we would have done this work three weeks ago. As soon as the leaves fall more, we will place all such plants closer together that we may find more room for beds of Strawberries under cover, Lettuces, Cauliflowers, &c. Commenced washing Vines in first house with hot soap water after the above smoking. Washing also the glass, wood-work, stages, walls, preparatory to lime and sulphur white-washing the latter, and cleaning the house thoroughly before filling it with plants, which will remain until the necessary heat for forcing the Vines is too much for them, when they must be removed. We would have used a little sulphur in smoking this house before washing, as the wood is hard, but we were afraid that some of the fumes might find their way into the next house, where they would have done injury. Our Vine-borders are still unprotected, for they were so dry that a little moisture would do them good.

rather than otherwise. Wooden or asphalt coverings are capital things for keeping the borders in a right state as to heat and dryness.

After this rain preparations should be made for planting, replanting, and root-pruning fruit trees, according as their circumstances may require. Many kinds of fruit liable to have the wood cankered and spongy, will be kept healthy and well ripened if the trees are lifted and replanted every two or three years. These when surface-mulched and replanted in good time in the autumn will scarcely feel the effects of the moving more than their making for some time less vigorous wood, which will, consequently, be better ripened, and more furnished with fruit-buds. For all small gardens especially, these stunted but yet healthy and fruitful trees are the things to be aimed at, so that you can walk about the tree, and do to it everything it needs on *terra firma*, and require no long dangerous ladders on which to mount and lean to some tempting branch until ladder and you come to grief.

There is with hardier trees often two ways of attaining the same result. You may wish to fill a certain space with wood quickly, and not mind sacrificing fruit at first to growth. In that case you may encourage rather strong growth, and then, when the space is nearly filled, relift and plant or root-prune carefully in September, and if you have a fine autumn you will most likely have a preponderance of fruit over growth for some years afterwards.

ORNAMENTAL DEPARTMENT.

As soon as the ground is moist enough, all sorts of shrubs, and evergreens especially, should be planted or replanted. If the ground is still dry the holes may be opened, and thus the exposed soil will be ameliorated, and any stopping or pruning that the head requires should be given though it would have been better if that had been done a month ago, or more, as was previously alluded to. Any shrubs or trees deemed rather tender for the climate, should be planted on knolls, so that the more limited growth in consequence may be better consolidated. The stronger Roses may be at least partially pruned, to prevent the winds swaying them so as to affect the roots. Tender Teas, &c., in beds, in cold places, may as well be taken up and put in thickly by the heels in a sheltered place, or under a shed with some hay or fern ready at hand to place among the branches, if severe frost should come suddenly.

Laying turf may be proceeded with as soon as the turf is damped sufficiently to render watering unnecessary. This is better done now than in spring, chiefly for three reasons—first, it is more pleasant to do the work, and there is more time generally to spare for the doing it, and it will be well consolidated and levelled before spring, and want thus scarcely any attention then, which it will do if deferred until March or so, and the weather should prove dry and parching.

We have frequently known old pasture because not level enough for a lawn, dug or trenched down to admit of the ground being levelled, and then great trouble and expense incurred to obtain what was considered good turf from the sides of some country road, though most likely well-stored with the little plants and the seeds of Daisies, Plantains, &c. A better plan in most cases would be to roll the rough pasture, mow it close, and sweep it hard, and then take up and replace again as you level, and if you think proper, scatter a little Dutch Clover and a few fine Bents over the turf before you finally roll it down.

We have at last taken up some Cloth of Gold, Golden Chain, Alma, and other Geraniums, and in taking them up the secret was disclosed how they stood so well with us in this dry season when we had no water to give them. We traced the roots of many fully 3 feet down. Could the Calceolaria be induced to send its roots down like the Geranium, it, too, would stand the dry weather better. That we got on as we did in such a season we have no doubt, as we previously stated, was owing to the deep stirring of the ground. We found Geranium roots much deeper than the above, but we question if they would thus have found their way down so easily, if there had been a hard pan some 12 inches from the surface, that no utensil or pointed lever-power had ever broken up. Just before the wet we also managed to go over a great quantity of small cuttings in pots and boxes, stirring up the surface soil with a pointed stick, and in many instances removing a portion where there was the least sign

of damp or fungus, and replacing with a sprinkling of fresh loam, rendered light by drift sand and charcoal dust. We shall be anxious to keep these as much as we can under protection out of doors as long as possible, instead of cramming fruit-houses at once. Will also take care that no plants or boxes of plants are housed for the winter until satisfied of their being free from all kinds of insects, as it is of little use cleaning houses as a preventive of evil, and then let the evil enter with our own consent.

As stated some weeks ago, Auriculas, Polyanthus, Carnations, and the more tender alpines, should now be protected from soaking rains, and whenever frost is feared earth should be piled several inches high round the stems of Dahlias to prevent the buds being affected. Gave all the air possible to Chinese Primroses, Violets, Mignonette, Cinerarias, &c. Tree or pyramidal plants of Mignonette, the best of all for winter cutting, should be kept in rather a dry atmosphere. Brought on forcing plants very gradually, and lessened the bulk of the climbers in greenhouse and conservatory to give more light to the plants beneath. Washed off the rough of the shading that had been given to such houses and pits and frames in summer, to lessen evaporation when we were so short of water. Gave all the light and air possible to stove plants to firm their growth, and helped them also in damp weather with a brisk fire for two or three hours during the day.

Charring.—From the most unpromising rubbish we obtained a load or two of small charred material, and the remainder, being more twigs with leaves than anything else, we will burn, and with it a great lot of earth and weeds; the produce will lighten parts of our heavy land.

Getting up some turf for future composts from a paddock where a road is to be formed, and the sides planted, has occupied, and will occupy, a good deal of time. We allowed the material to be slightly damped, and then commenced building it in stacks 4 feet wide. By next summer it will be good stuff.—R. F.

COVENT GARDEN MARKET.—OCTOBER 29.

We have nothing fresh to report. Grapes continue plentiful, and Pines are still scarce; in Apples and Pears the kinds remain the same, and the supply is heavy. Large importations of foreign Grapes are still arriving, also Oranges of the new crop, but the latter not in bulk as yet. Of Potatoes the consignments are very heavy.

TRADE CATALOGUE RECEIVED.

William Chater, Saffron Walden Nursery.—Catalogue of Superb Double Hollyhocks and Choice Pansies. 1864-65.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

SEEDLING POTATO. HAND'S FREEDOM.—This, which we noticed as exhibited at the Royal Horticultural Show, was raised by W. Hand of Newcastle-under-Lyne, Staffordshire, and not of Newcastle-on-Tyne.

LILUM LANCIFOLIUM CULTURE (F. W. B.).—These Lillums withstand the winter when planted 6 inches below the surface in light loamy soil, but require the protection of a greenhouse or a cold frame when grown in a pot. The bulbs, when the foliage decays, should be potted in light, rich, turf-like loam, with good drainage. Little water must be given during winter, but sufficient to keep the soil from becoming dry; and a plentiful supply should be afforded when growing. It may be grown in a pot in a cold greenhouse or frame, having abundance of light and air. The other we do not know under the name, nor are we aware of any such plant, and we have grown them all.

LILY CULTURE (Idem).—The *Jacobs* Lily (*Hippeastrum*), should be grown in a pot. The idea that it will grow with air and light, without soil, is a fallacy. Pot in strong turf-like loam by February, plunge it in a hotbed if at command, and water sparingly until growth commences, then water freely, and keep well supplied until the foliage attains its full size, afterwards gradually diminishing the quantity until the leaves decay, and then discontinuing watering altogether. Winter in a dry airy part of the greenhouse in the soil in which the bulbs have been grown. When the flower-scape appears, and is on the point of expanding, remove to the greenhouse, where the plant will flower finely from April to June. *Cyclamens persicum* requires a compost of turf-like loam, peat, and leaf mould, in equal parts, with a free admixture of sand. It should be potted just when it commences to grow, or in September, providing efficient drainage. It should now be on a shelf near the glass in an airy part of the greenhouse, and be throwing up for bloom (our *Cyclamens* are in bloom), and should be watered, so as to keep the soil not very wet nor dry. After flowering, or in spring, remove to a cold frame, plunge in coal ashes, and after May it may be plunged out of doors, and left there until September, when it should be potted. We shall say something on the cultivation of Lillums and *Cyclamens* shortly.

LAWN-MOVING IN WINTER—IVY UPON OAK—YEW HEDGE INJURED BY DROUGHT (An Old Subscriber).—Unless the winter prove milder than ever was known the grass will not grow much, and will not require more than one mowing after this; or the final mowing may take place when the garden is cleared of leaves, and otherwise cleaned up for the winter. After that, rolling once or twice a week in mild weather, and keeping clean of leaves, &c., will be all that is required until April, when mowing will of course be necessary. Ivy planted by an Oak will be a long time ere it will exert any great influence on the Oak; but it certainly does injure all trees to which it is allowed to cling. It smothers them. We noted that some young Oaks with Ivy growing on the stem were much smaller and weaker than those without the Ivy. The Yew hedge will right itself if left alone. All that can be done is to mulch the ground for a yard on both sides of the plants with short litter or manure, let it remain on through the winter, and in March place an inch of mould on that. Liquid manure, if given at all, should be applied at every alternate watering, and only when the plants are growing. Copious waterings in dry weather are preferable to frequent waterings with manure water.

VINE MILDEWED—PEACH TREE WORTHLESS (P. B. F.).—Something is probably wrong with the roots of the Vine. They may have penetrated into ungenial, cold, wet soil, or the soil itself may be too cold and wet. If the soil is moderately light and open, and thoroughly drained, we should think the roots all right; but if the soil is wet, and there is no drain, the mildew is probably to be ascribed to that cause. If this is the case take up the Vine, preserving all the roots possible, drain the border, and render the soil lighter by mixing with it a quantity of lime rubbish from an old building. This should be done now or in March. You will gain nothing by cutting the Vine down, nor will you have any chance of remedying the effects until the cause is removed. By replanting and bringing the roots nearer the surface the cause may probably be removed; but if the mildew occur another year dust flowers of sulphur on the parts when it first appears, being careful to dust every part affected. Disease of the wood is more apparent in the bearing of the Vine the year following, than during that in which the disease appears. It would be better to plant a young trained Peach tree in place of the worthless kind. You may cut it down, however, and bud it next summer if you choose to do so, and do not mind waiting three or four years for a crop. The Royal George is a good Peach, and so is Grossé Mignonne. Peach trees are not grafted, but budded.

SPARAXIS FAILING (R. R.).—We think the failure was to be attributed to taking up and keeping in a dry place until the time of planting, when the roots, having lost their vitality, refused to grow. This is by no means an uncommon case, but very frequent with *Tritonia aurea* and some others, which ought not to be taken out of the earth at all, except for the purpose of replanting. They should be left in the pot in the soil in which they have been growing, and, though the soil may appear dry, there is a sufficient amount of moisture present to preserve the vitality of the roots.

DAHLIAS (S. B. O.).—The varieties are far too numerous and nearly alike to enable us to tell the names from such specimens. Not one of those sent is first-class, but they are very good for border flowers.

PIT SAND FOR POTTING (J. Bryan).—We know of no better mode of testing sand, except by analysis, than to place a portion of it in water and stir it about. If it dirties the water it is not pure silicious sand, and is not to be recommended for mixing with soil. In applying silica to plants it is best afforded in fine grains of silicious sand. Pit sands of all kinds, after being washed, and freed of their earthy particles, answer the purpose of mixing with soil; but the majority are, for the most part, little more than half silicious matter, and when wet little better than masses of mud. Such are to be avoided. The best of all sands is that found in peat soil, the next is silver sand, and the next best river sand, and the latter two are the only forms of silica available for potting purposes.

ARBOR VITE BROWNING—BOX TREE MOVING (W. Barker).—The brownness of the Arbor Vitæ is probably due to the drought. If it is only browned in foliage it may probably recover; but if the wood is brown, instead of green, when cut, we advise you to root the tree up, for it is dead. Once any of the Conifer tribe become ill-looking they rarely, if ever, recover. The Box tree may be removed with a prospect of success if it can be taken up with ball, or a mass of fibrous roots, and this may be done in April, in showery weather. You may cut it in but it would be best to defer that until a year after removal, cutting so that some green parts would be left. You may grow the Strawberries and pyramidal Apple and Pear trees in light sandy soil by liberal dressings of well-decomposed stable manure, or, what is better, cow-dung a year old.

MANAGING FIG TREES (E. M. W.).—When the Fig trees are matted up for the winter the Figs should not be removed, except those which are nearly full-sized. These may be removed, as they seldom swell after the protection is taken off in spring, but turn yellow and fall off. Any of the size of a hazel nut should be preserved. The ends of the shoots should not be shortened either in autumn or spring; but when the protection is taken off, if the branches are nearer together than 9 inches when spread out, the old long branches with few young shoots upon them should be cut out to the bottom, so as to admit of the branches left being trained in at from 9 inches to 1 foot apart. If they make shoots a foot or more in length in a season, stop them at the fifth leaf; but if the growth do not exceed five or six leaves annually the shoots should not be stopped, but trained in at their full length. Any shoots that tend to fill the tree with wood should be cut clean out, so that air and light may be admitted to the fruit and promote the ripening of the young wood. As the trees are vigorous, we do not think an application of manure to the soil would be of any advantage, but would tend to encourage growth rather than the maturation of the fruit and wood.

ENTRANCE GATE (H. T. H.).—We cannot furnish such a plan. It would be too costly to furnish a drawing to all who require working plans.

MUSHROOMS IN LONDON CELLARS (L. T. S.).—Mushrooms may be grown in cellars more successfully, perhaps, than anywhere else. Unless the cellar reached about 55° in winter the bed would require a little protection from dry hay or something of that kind being shaken over it. In summer they do admirably in cellars, because there they are easily kept cool. They will not, however, succeed in cellars any more than anywhere else, unless the spores or spawn run in decomposing organic matter, in which the more animal droppings there are, as that of the horse, the better. Of course there is trouble in taking that material out and in. To lessen that trouble so far we have filled large pots, about 18 inches in diameter, or tubs, or boxes, capable of being easily carried by one or two persons, and filled, spawned, and earthed them before taking them to the cellar, treating each one just as we would do a bed. This lessened the litter in the cellar. Treat your dung as you may, you will be apt, especially if the garden or the house is old, to take some woodlice in with it, which of course will grow bigger, and must be trapped as elsewhere. We know of no other insect that will be apt to trouble you if the droppings are well heated before being used. We have seen fine Mushrooms, Sea-kale, and Chicory, in London cellars.

CLIMBERS FOR VERANDAH TRELLIS (T. R. S.).—We have no doubt that the Roses you name will do well enough if you give the ground a good dressing of rotten dung, well incorporated with the soil, and then in summer mulched the ground over the roots with more rotten dung. No doubt your soil is too poor. If you wished a change, we have no doubt that Honey-suckles and Jasmines would do, choosing the hardiest kinds, as the hardy Chinese yellow Jasmine for winter, and the white for summer. We have no doubt, however, of the Rose, but it may be necessary to replant. Prune, and wash with Gishurst, or something of that kind, to get rid of insects and their eggs.

BLACK HAMBURG GRAPES NOT COLOURING (A Young Gardener).—We fear there is something wrong either in the border or the materials of which it is composed. Generally speaking, Grapes have coloured well this season; but you may perhaps have overcropped the Vines, or a too severe pruning of the summer wood, or its opposite by preventing light and air acting on them, may have something to do with it. Your border, which you say is 3 feet deep on a two-foot drainage, is ample enough, or perhaps a foot too deep, and we apprehend if the roots were examined they would be found near the bottom—very likely amongst the drainage and beyond the action of the atmosphere. Soil for Vine-borders ought to be open rather than rich, and when there is the happy mixture of the chemical constituents required in the food of the Vine, the latter thrives almost in spite of mismanagement. When the mixture is an artificial one there is more uncertainty. In your case we would be disposed to lift the Vines carefully and replant them in a soil more in accordance with their requirements in this country. Some articles on this subject will shortly appear in this Journal. The evil in the case of the Muscats arises from a like cause.

SOWING VARIOUS SEEDS (Mary Scott).—*Ageratum mexicanum*, *Arctotis grandiflora*, *Heliotrope*, *Portulaca*, and *Anagallis* seeds, should be sown in the first week in March, in pots of light sandy loam and leaf mould, covered lightly with soil, and placed in a gentle hotbed. Pot when large enough—two, three, or more round the side of a small pot, or the first three and last singly, according to their strength, and grow on in a greenhouse, hardening off in a cold frame. *Alyssum compactum* is a hardy plant blooming in spring, and should be sown out of doors in May. *Linums* are a numerous family, and you do not say which yours is, so we imagine it to be an annual that may be sown in the first week in April where it is intended to bloom, or in pots under glass in March; if a tender sort, to be planted out in May. *Sedum* may be hardy or tender, but we presume the former, to be sown out-doors in May, but it will not flower the same year. One of the seeds named we were unable to make out.

FURNISHING BOTTOM HEAT TO PINE PLANTS (St. Omer).—You are quite right as to your plan being novel; and its answering the purpose for which it is intended is a great point in its favour. We never did see any advantage in placing rubble over the pipes, knowing, as we do, that the heat rises, and warms the bed more over the pipes than elsewhere; but we do see advantage in placing the pipes in an open chamber, and covering that chamber with open slates, or slabs of stone, by which the bed above is equally heated throughout. Such is your system, only you employ wooden sleepers and drain tiles, instead of tine or slate coverings. Though there be a variation of materials the system is the same.

GATHERING BRUSSELS SPROUTS (E. C.).—When the Sprouts are large enough for gathering then is the right time, and as for their being only fit to use after frost, it is like saying that summer Cabbages are not worth eating. We cut them as soon as we can, or when about the size of a tenio ball, and quite firm, for if not used they will open or become loose, and are then no better than Coleworts. Try them, and we feel sure you will like them. We have used ours since September, and like them better than anything at this season.

HEATING A CUCUMBER-PIT (J. B.).—For a pit 36 feet long, sunk below the ground level from 18 to 24 inches, width 7 feet, height at back, inside, 8 feet, and in front 6 $\frac{1}{2}$ feet, a flow and return three-inch pipe, along the front and one end, would only do for Cucumbers planted out towards the end of April. To plant out about January you would need the double of what you have now; and to keep on in severe winters you would need a fifth pipe, if you could give no protection to the glass on very cold nights. Your tank or box over the pipes, 18 inches deep and 12 wide, will do to grow the plants in, if planted at first some 5 inches from the top, and gradually earthed-up with rich light compost. We do not think raising the pipes will give you any advantage. The top of your tank should not be less than 15 inches from the glass, and your trellis at the back wall should be fully more—say 18 inches—and that will give room for the foliage. We do not see how “taking the glass off, and the pipes away, would make a nice house.” We can well fancy how, by raising the back wall 18 or 24 inches, lengthening the sashes to suit, or having an opaque part at top, where air could be given, and doubling the pipes, you might have a nice Cucumber-house.

WINTERING GERANIUMS AND FUCHSIAS (K. C.).—If the Geraniums are variegated-leaved kinds, you must not cut them in; but if Scarletlets they should be cut in and diseated, if to be kept in the dark (in that case cutting in but little); but have the leaves left on if they have light. Give only a little water to prevent the plants drying up, but afford air and plenty of light if exposed to it at all. Little if any water will be needed before March, but if the soil is very dry, a little should be given on the morning of a fine day when it is likely to be dried up before night. Fuchsias should not have any water from this time until March, when they may be cut in, and watered a little at first, increasing the quantity as the plants advance in growth, repotting them when the shoots are 1 or 2 inches long. If the situation in which they are kept during the winter is very dry the soil may become too dry, they should therefore be examined, and a little water given if the shoots show a tendency to shrivel. Fungi domo is a good material for keeping out frost, and so stout canvass, but the first is to be preferred.

CONSERVATORY STAGE (A. Subscriber).—If you have glass for half your height in front, why not have a low stage all round, and the walk up the centre? or even if you had a flat stage of 2 $\frac{1}{2}$ feet in front, and a raised stage of 4 $\frac{1}{2}$ feet for base at back, you would get at your plants with greater ease than on the broad stage you propose. The number of shelves must be determined by the size of the plants. For small plants the shelves may be only 6 or 9 inches below each other. For large plants they might need three or four times that space. If you have no glass in front of your house your proposed plan will do.

CAMELLIA BUDS FALLING (Perplexed).—There is nothing noxious in the water. Sudden transition from moist air to dry air and more heat is a probable cause of the buds falling. The cause of the plants in the viney not dropping their buds is probably due to the greater moisture, and cooler and more shaded state of that structure. Another very likely cause is the conservatory being badly ventilated, as Fuchsias, Citrons, &c., have not done well in it. Was the house painted? If so, the plants were probably put in before the fumes of the paint had gone off. Perhaps the plants have not been kept well supplied with moisture, or watering may have been overdone, either of which conditions will cause the buds to fall. You should have thinned the buds to at most two on a shoot. The enormous quantity borne at the point of the shoots, judging by that sent, is more than any plant can swell, support, and properly expand. Then the Citron leaves are infested with brown scale, which you will find on looking at the under side next the midrib, and the insect would be better removed with a sponge and a solution of soft soap, not too powerful. That, however, has nothing or but little to do with the leaves falling, and that, we think, is due to one or other of the causes named; the buds sent have been defective some time, especially the small ones.

VINE ROOTS IN OLD TAN (A Reader).—We would remove the tan now, and replace it by turves cut 2 or 3 inches thick from a pasture where the soil is of a light loamy nature, being careful not to injure the Vine roots in removing the tan; and in placing the turves, which are all the better if from three to six months old, lay the roots in them, covering about 6 inches deep. You will find this much better than tan for Vine roots to ramify through, and it will be a new source of strength to the Vines. We have in the press a work on Vine culture, which will treat fully on the subject.

PRESERVING CUCUMBER POLLEN.—*ECHIUM CANDicans* (October).—We do not perceive what is wanted with the pollen for winter impregnation, as Cucumbers swell their fruit as well unimpregnated as impregnated, and are much better for use as they are without seeds. We never experienced any deficiency of male blooms in winter, it might be because we took off all we could put our hands on, yet we always have more than we want, and that is none. You may keep the male blooms in a closely-stoppered phial, putting them therein when the pollen is ready for shedding, or you may collect some of the pollen on white paper, and keep it in a sealed bottle, not to be opened except when used, but we question its utility. From your large plants of *Echium candicans* you may expect some handsome blue flowers in May or June of next year, if you keep the plant in a light, airy situation in a cool greenhouse, and do not over-water them during the winter. The spike of berries sent belongs to some *Phytolacca*, probably *Phytolacca decandra* or Virginian Poke, but for certain identity, foliage and flowers should have been sent.

GRAFTING CAMELLIAS (Pond-dhu).—Camellias may be so managed, as well as Oranges, and any time before fresh vigorous growth takes place in the spring. In all cases, however, where the grafted plants could be placed in a moderate moist heat, there would be no necessity for leaving any part of the bottom end exposed. We have grafted even large plants of Camellias all over, watered the plant well, then laid the head down over a slight sweet hotbed, and placed a sash from a frame over it, and a mat at each side. The plant was moved once or twice to give water, before the scions commenced to grow freely. We would recommend, as a suitable Peach for your orchard-house, Walburton Admirable. Coe's Golden Drop Plum is anything but a shy bearer under glass, but it must have abundance of air when in bloom. We believe that in a house with air full on, and a little shaded in summer, so as to retard the crop, this excellent Plum might be kept almost till Christmas, and then in saccharine matter be more like a preserve than a Plum.

PLANTING A VILLAGE CHURCHYARD (Tea Rose).—But for what you say about the windows being shaded, we have no doubt the nurseryman's selection would suit you. Keeping that in view, we would be disposed to place a Chinese Arbor Vitæ in the centre, and in a circle, 6 feet from that, we would plant four Laurels (*Portugali*), and four Hollies, alternately with each other; and then, 4 $\frac{1}{2}$ feet farther, presuming that the diameter of circle is about 23 $\frac{1}{2}$ feet, we would plant a row of *Laurustinus*. The Portugals could be nipped-in as the Hollies grew. To make an appearance at once you might plant common Laurels, pegging them down over the ground. Is it necessary to have that circle at all? Round the sides, where there is room, we would put a plant or two of the common Yew, the Irish Yew, common Arbor Vitæ, and Cypress. A Deodar would soon want the clump for itself. If there were no circle you might have an *Araucaria* opposite the entrance, and a Deodar at each side, so as to avoid the windows.

NAMES OF FRUIT (J. P.).—**Pears.**—1, Catillac; 2, Doyenné Bousooch; 7, Chaumontel; 8, Conseiller de la Cour; 9, Vicar of Winkfield. **Apples.**—1, Franklin's Golden Pippin Apple; 3, Golden Russet; 6, Golden Winter Pearmain; 13, Dumelow's Seedling; 14, Lady's Finger; 15, Hollandbury. Others not recognised; and we are not sure we distinguished correctly the 6 from the 9. (*W. R.*).—2, Lewis' Incomparable; 3, Wyken Pippin; 4, Winter Majestic; 6, Wormsley Pippin; 7, Catshead; 8, Golden Reinette; 9, Yorkshire Greening; 10, Winter Queening; 11, Dumelow's Seedling; 12, Crimson Queening; 13, Beauty of Kent; 16, Early Nonpareil; 18, Syke House Russet. (*Constant Lender, Ross*).—**Pears.**—2, Hacon's Incomparable; 3, Passe Colmar; 4, Gloucester; 5, Brown Beurre; 7, Easter Beurre. **Apples.**—1, Blenheim Pippin; 2, Norfolk Beefing; 4, Dumelow's Seedling; 5, Cox's Orange Pippin; 8, Court of Wicke. (*M. S., Holland Road*).—**Your Pear is Uvedale's St. Germain.** (*H. J. Watson*).—1, Winter Pearmain; 2, Bezi de Caissey, which from November till March, ripening in succession; 3, Chaumontel. (*A. W.*).—Your Apple is the Golden Noble. Where numbers are omitted the fruit to which they were attached was not recognised. (*J. Bennett*).—1, Passe Colmar; 2, Zéphirin Grégoire; 3, Joséphine de Malines. (*A Young Pomologist*).—Your Apples were named at page 239. We do not remember the Pears.

NAMES OF PLANTS (Dublin).—Your Fern is *Athyrium Filix-femina*. (*J. Smith, Orton Hall*).—1, *Asplenium adiantum nigrum*; 2, *Asplenium trichomanes*; 3, *Polyodium Robertianum*; 4, *Polypondium dryopteris*; 5, *Polystichum aculeatum lobatum* in a young state; 6, *Polystichum lonchitis*. (*Johnny Tucker*).—1, *Rhipsalis* crushed—perhaps *cassytha*; 2, *Arthropodium paniculatum*; 3, *Rhipis repens*; 4, *Gymnogramma tartaera*; 5, *Some Saxifrage*; 6, *Serissa foetida*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE ORIGIN OF BRAHMA POOTRA FOWLS.

I FEEL sure it would give much satisfaction to a large section of the poultry world, as well as to myself, if some of your correspondents who are learned in Brahmans, would be so kind as to give us some information through your columns which may tend to throw some light on the question at present so unsettled, “Are they a true breed or not?” And I hope they will accompany any communications with some reliable data on which their opinions are formed.

In your last Journal, I see you state that you consider them either a variety of the Shanghai, or a cross of the Malay, and as some maintain them to be a distinct breed, I presume we have here the three points between which opinions vary.

Having only kept them for a myself short time, I do not feel competent to form a decided opinion; but I must confess, as I kept Cochins at the same time, I could not help noticing peculiarities in their habits which disposed me to lean to the opinion that they were decidedly not Cochins. Indeed, of this I feel certain, but then it is evident those peculiarities might have been introduced by a “cross.”

I am, however, disposed to think that if the breed had been obtained by crossing, they would occasionally “throw back,” but I never heard of such an occurrence. Certain it is that they are a most valuable kind of poultry for all purposes, whatever be their origin; and although I do not at present keep poultry, I join with many others in regrets that such determined efforts should be made to deny them the place they deserve.—W. H. B.

[Dr. Gwynne, of Sandbach, Cheshire, was one of the first to possess this variety, and he informed us that he obtained them from Dr. Bennett, of the United States. He at

once concluded that they were either a mere variety of the Cochin-China, or a cross, "probably with the Malay." He asked for information from Dr. Bennett, but could obtain no satisfactory reply, and why he could not is fully apparent from this which we extract from an American work on poultry.

"The variety of fowl itself was the Grey Chittagong, to which allusion has already been made, and the first samples of which I obtained from 'Asa Rugg' (Dr Kerr), of Philadelphia, in 1850. Of this no one now entertains a doubt. They were the identical fowl, all over,—size, plumage and characteristics.

"But my friend the Doctor wanted to put forth something that would take better than his 'Plymouth Rocks'; and so he consulted me as to a name for a brace of grey fowls I saw in his yard. I always objected to the multiplying of titles; but he insisted, and finally entered them at our Fitchburg Dépôt Show as 'Burram-pooters,' all the way from India.

"These three fowls were bred from Asa Rugg's Grey Chittagong cock, with a yellow Shanghai hen, in Plymouth, Mass. They were an evident cross, all three of them having a top-knot! But, *n'importe*. They were then 'Burram-pooters.'

"Subsequently, these fowls came to be called 'Burram-pooters,' 'Burram Putras,' 'Brama-pooters,' 'Brahmas,' 'Brama Puters,' 'Brama Poutras,' and at last 'Brahma Pootras.' In the meantime, they were advertised to be exhibited at various fairs in different parts of the country under the above change of titles, varied in certain instances as follows; 'Burma Porters,' 'Bahama Paduas,' 'Bohemia Prudas,' 'Bahama Pudras'; and for these three last named, prizes were actually offered at a Maryland fair in 1851!"

BLACK IS WHITE.

CONTRADICTORY as this may seem, it is no less strange than true, that what was black is now white. But to my story. A neighbouring farmer purchased some chickens two years ago, and among them was a single black one, which in due time became a hen, and underwent the usual cares of henhood. Now, whether these cares or female vanity, aroused by the fact of being a solitary black one among so many of various gay colours, or both, preying on a peculiarly constituted mind, produced the effect I am about to describe I must leave my readers to decide; but certain it is that after twelve months this black hen was observed to be changing her plumage, until at eighteen months old she became black and white; and the change still going on at two years old this once jet black hen, black even to her legs, became, and is now, of the purest milk-white, with legs as white as any Dorking's. The hen is now in my possession, having been kindly given to me on expressing much interest in the matter; and the above facts can be vouched for as strictly true. May I ask if such a case of washing a blackamore white has been met with before?—R. O., Eglingham.

[Many instances have occurred, and some have been noticed in our pages of Black Spanish hens gradually acquiring an entirely white plumage.]

TYLDESLEY AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE thirty-first annual Show of the above Society was held on the 20th ult.

GAME.—First, J. Hilton, Boothstone Bridge. Second, T. Wakefield Golborne.

SPANISH.—First, W. Gregory, Atherton. Second, J. W. Speakman, Atherton.

COCHIN-CHINA.—Prize, T. Wakefield, Golborne.

DORKING.—First, S. Farrington, Astley. Second, J. Bullough, Atherton.

HAMBURGS (Golden-pencilled).—First, J. Morris, Westleigh. Second, T. Davies, Hindley.

HAMBURGS (Silver-pencilled).—First and Second, J. Platt, Deane.

HAMBURGS (Gold-spangled).—First, J. Walton, Hindley. Second, J. Morris, Westleigh.

HAMBURGS (Silver-spangled).—First and Second, J. Morris, Westleigh. Highly Commended, J. Haslington, Tyldesley.

POLAND.—First and Second, S. Farrington, Astley.

BANTAMS.—First, R. Gerrard, Atherton. Second, S. Farrington, Astley. Commended, S. Farrington.

DUCKS.—First, T. Wakefield, Golborne. Second, J. Newton, Astley. Commended, J. Gregory, Hindley; J. Bullough, Atherton.

GESE.—Prize, W. Green, Little Hulton.

Mr. John Elliott, Westleigh, officiated as the Judge.

COWS ROBBED OF THEIR MILK.

You are correct in stating that the idea of hedgehogs sucking cows has long been abandoned by naturalists, the chief reason being, I believe, that the mouth of the animal is not large enough to admit the teat of the cow. The suggestion that the human hand drew the milk from your correspondent's cow is the most probable one, and she *may* have sucked herself; but I venture to suggest that a more common thing to have occurred in that way, would be that one of the cows running with her was perhaps the culprit.—W. H. B.

IS A NEW BEE BOOK WANTED?

"O, that mine adversary had written a book."—JOB xxxi, v. 35.

I JOIN most cordially in the request of "R. S." Mr. Woodbury would confer an inestimable favour on the whole community, whether bee-keeping or honey-loving, by writing on a subject in which, we may say without depreciating others, he is "*facile princeps*."—A CONSTANT READER.

[The request preferred by "R. S." in page 319, seconded as it is by "A CONSTANT READER," has brought the above question very forcibly to my mind, albeit by no means for the first time, since, I may confess, that I have long contemplated such a task, and have spared neither labour nor expense in obtaining information and experience to qualify me for it.

My idea is, that the work should first appear in the columns of THE JOURNAL OF HORTICULTURE, whence it would afterwards be reprinted and offered to the bee-keeping world at a moderate price.

For upwards of six years I have been a very frequent contributor to the pages of this Journal, and I have to acknowledge with gratitude the kindly appreciation which has always been accorded me. To this correspondence I owe the commencement of many valued friendships, and am indebted to it for numberless pleasing episodes and grateful reminiscences. Whatever information I possessed has always been freely communicated to all, whilst in my turn I have derived much advantage from the interchange of ideas with others. May I venture to hope, that if it be decided that I am to write a new bee-book, it would be received by the Editors and readers of THE JOURNAL OF HORTICULTURE in as kindly and indulgent a spirit as the nearly hebdomadal contributions of—A DEVONSHIRE BEE-KEEPER.

[To this reply we give a ready insertion, and should feel that we did an injustice not only to the writer but to our readers if we did not cordially assent to the proposal. We look forward with confidence to the work as one that will be of great utility; for Mr. Woodbury possesses not only knowledge of the habits of bees and of all the literature on the subject, but a long experience in the apiary, and is fully qualified to teach how to manage them under any system, whether for amusement or profit.—Eps.]

WOODBURY FRAME-HIVES.

"A. W. B." says that the frames in his Woodbury's bar-frame-hives "got a little out of the perpendicular as soon as the bees began to work, and thus scarcely any of the combs are true, and many are joined together, so that the frames are useless." I have heard the same complaint from many bee-keepers that use these hives. In reply to his inquiry you say, that "every Woodbury frame-hive is furnished with a notched bar fitted transversely at the bottom of the hive. Each frame drops into its appropriate notch, and is in this way kept perfectly steady and perpendicular until filled with comb. When this has been accomplished the notched-bar had better be removed, as the weight of the combs renders its presence unnecessary, and it would be a hindrance to their free manipulation." With all due deference to Mr. Woodbury, the time that he removes his notched bar is the very time it is most required, as the

bees do not fill both sides of all the combs equally with honey, but sometimes put three or four times more weight of honey at one side of the comb than at the other, and the weight on the heavy side not being in the centre throws the bottom of the frame against the next comb, until the weight is balanced in the centre. The bees then have to shorten the cell that presses against the next comb. In turning the hives over to take to the moors, or for any other purpose, his bar-frames all tumble-together whichever way the hive leans on its side, and so crush and kill the bees between the loaded combs. Mr. Woodbury's notched bar also rests upon the floor-board, and so prevents all the dirt being easily removed out of the hive from behind it. In my improved bar-frame hives the notched bar is fixed on the ends of the hive, and the hive can be turned over on its sides or in any other way when the cover is screwed down, and not a single bar-frame or comb can get out of its place. Many Woodbury-hives have been altered to my plan, and their owners all say it is a great improvement. It does not in the least interfere with any manipulations in taking out or putting in the frames, but rather assists the bee-master in guiding the combs exactly to their place again when put back in the hive.—WILLIAM CARE, *Clayton Bridge Apiary, Newton Heath, near Manchester.*

[The foregoing objection is wholly imaginary. When a comb of moderate thickness is fixed in its place in the centre of a bar, it is absolutely impossible so to distribute the weight of honey which it will contain as to cause its frame to deviate even in the slightest degree from the perpendicular. Whenever this occurs after a frame is filled with comb, it must be attributed to defective workmanship in the frames themselves. If a hive is to be turned on its side or inverted, the combs and frames should be secured accordingly; but we regret to learn that Woodbury-hives have been tampered with in the way described by Mr. Carr, as notched bars have not been discarded from them without sufficient reason. No frames can be readily or conveniently manipulated which have to be dropped into notches, and it makes no difference in this respect whether these be in the centre or at the ends of the frames.]

ARE BEES CARNIVOROUS?

WITHOUT wishing to give any offence, or be considered unpolite in doubting a lady's word, I cannot but think that bees do not eat meat; and I shall be glad to hear what your able correspondent, "A DEVONSHIRE BEE-KEEPER'S" opinion is on this subject, as I have so often observed when bees have been said to eat this, that, or the other that has been put into their hives, that they have only taken it out to get rid of it, as witness the grains of candied honey and undissolved sugar, &c., they bring out; but when I have a hive that I do not care for I will certainly give them some meat, and then watch them closely to see if they do consume it.—A. W.

[My opinion is identical with your own; but we shall soon have the matter placed beyond doubt, since "R. S." has responded to the appeal in page 246 by submitting the alleged carnivorous propensities of bees to the test of experiment, and will ere long be in a position to report the result.—A DEVONSHIRE BEE-KEEPER.

We have another communication on the same subject decidedly evidencing that bees are not carnivorous. It will appear in our columns next week.—EDS.]

UNITING QUEEN TO BEES—WASPS EAT BEES.

I THINK the want of success in introducing Ligurian queens into stocks of black bees, is in consequence of allowing the queen to go into the hive too soon after the removal of the black queen.

I find that fumigation injures the constitution of the bees; and although they appear to recover perfectly, the mortality afterwards is very great and rapid. The queen does not appear to suffer so much from the fumes as her subjects.

I have just placed a Ligurian queen at the head of a black stock with perfect success. On Monday last I received from Mr. Woodbury by train a Ligurian queen, and lost no time in removing the black lady from one of my stocks on

Tuesday. After allowing the bees to communicate with the strange queen through zinc for some hours, I let her go down into the hive; shortly after I had to release her from a cluster of workers, and had some difficulty in getting her from two bees who had her firmly pinioned by each wing. The next day about 3 P.M., after great management and caution on my part, she was received with the greatest affection, and pollen was taken into the hive.

The bees do not as a rule sting the queens, but smother them. This, however, may depend on the temper of the bees: some are much more irritable than others.

Have any of your correspondents noticed that the wasps eat the bees alive in their hives? They eat the soft part of the body, leaving the trunk and head walking about the floor-board. This is only, I believe, in weak stocks; strong hives do not, I think, suffer in general from them.—J. L.

[There is very great uncertainty attending the introduction of a strange queen, and you were very fortunate in inducing your bees to accept the alien monarch after they had once imprisoned her. We have on more than one occasion known queens destroyed after they had been permitted to lay eggs, and have often seen queens stung by workers.

We can confirm your statement as to the way in which wasps serve living bees. We have seen them treat both bees and daddy longlegs in this manner.]

BEES AND THEIR MANAGEMENT.

(Concluded from page 302.)

Now for one of the greatest difficulties in this department of bee management which I ever encountered, but yet combined with one of the most striking and instructive facts in the natural history of the bee which I ever witnessed. My first and best swarm came out about eleven o'clock in the morning of Whit-Monday. It was soon hived and protected from the intense heat by the shade of a kitchen table-cloth and an umbrella. In about an hour and a half afterwards another swarm was on the wing, and just as I had secured it the first swarm left its hive, and rising 20 feet or more above its domicile, commenced a gyratory progressive movement in the direction of a thick wood about a quarter of a mile distant. I almost despaired, but with two other helpers started at once in hot pursuit, equipped with bee-dress, brush, and hive. The bees made straight for a large ash tree, encompassed with the thick foliage of the surrounding copse, through which they took their course unerringly to a small round hole, scarcely half an inch across, in the upper part of the trunk. I knew the tree well, but was not aware before that it was hollow. The damp had penetrated into some old wound, over which the albumen had closed, giving to the trunk the appearance of perfect soundness. My hope of recovering that swarm was at first very slight indeed, but I saved it after all, and in this way. I suspected that, notwithstanding the specious appearance of the tree, it was unsound throughout, and that if I dug between the roots a little below the surface of the soil I might open communication with my bees above. My conclusions were soon verified, and, by dint of digging and cutting, I opened a hole at the bottom of the trunk large enough to admit my hand, and soon obtained evidence, from a mass of fine touchwood raspings, that the bees had been at work with their mandibles for some days past in scooping out a new domicile in close contiguity with the point of ingress. Only one chance remained for me, and that was to start them afresh by making their new home as uncomfortable as I could. My plans were laid and adopted in a quarter of an hour. I had recourse to the magic puff ball, *Lycoperdon giganteum*, a piece of which, as large as my fist, I lighted and placed in the hole. The difficulty to displace the air above was at first insuperable; I could not create a current from the smallness of the opening above. Three pieces of buff ball I burnt in this way in vain. I next had recourse to the flame of lighted paper, and in about an hour and a half could just perceive a small quantity of damp smoke issue from the hole, followed by a stream of bees. But, alas! the smoke soon subsided, and my bees returned. Knocking the trunk and blowing through the hole with a pair of bellows were equally in vain. My *dernier ressort* was brimstone—for my

only alternative now was to "kill or cure." As its fumes rose slowly to the hollow, there was a terrible commotion among the bees, and in a few minutes some dozen or two fell suffocated on the brimstone paper. I feared for the queen, wondering whether she would have time to free herself from the embraces of her loyal subjects before her doom was sealed. The outside of the tree was now covered with bees running about, many of them feebly, in a state of wild excitement. I had only to wait a couple of minutes to see a cluster forming on a blackthorn tree not ten yards distant—the queen was there, and in ten minutes the swarm was safely hived. I took it home in triumph an hour or two after sunset, for I never, if I can help it, move a newly-hived swarm to its final destination before that time. It is now a first-rate stock, full of bees and honey. I have no doubt whatever, both from the line of flight and the evidence already noticed, that the bees were instinctively moving to a previously selected habitation; and I have as little doubt that the swarming of the first colony from the hive in spring is nothing but a general muster, that all the emigrants may take wing together under the direction of experienced guides to a home of which they have already received ample information. This is merely a fact corroborative of a long broached idea, and illustrative of one of the wonders of animal instinct. Here is another analogous fact, which I relate, because it supplies the only missing link in the chain of my deductions. I can vouch for it by personal inquiry and inspection. A swarm of bees, belonging to a cottager living in a village about three miles from hence, made directly for a small crevice between the arch and woodwork of one of the windows of a house in the same village. That they did not alight there by mere accident is evident from the circumstance that a number of bees were observed reconnoitering that very crevice, which seems to communicate with the ceiling joists above, two or three hours before the arrival of the swarm.

Fourthly. With respect to ventilation, a subject the rationale of which every bee-keeper ought to understand, and one as important for the sanitary condition of the hive as for that of the cottage, I have adopted the following expedient for frustrating the invariable effort of the bees to stop up with propolis, the smaller perforations of the zinc plate usually employed to admit air and exclude insects. I cover the opening for ventilation with two zinc plates of different size perforations. The inside piece has holes of a size just sufficient to prevent a bee from passing through, and is placed a quarter of an inch or so in front of the other, which is perforated more finely. This requires the removal of the glutinous barricade much less frequently than would be the case were there no intervening piece between the bees and the smaller perforations. With respect to the system of ventilation adopted by the bees themselves, by which a certain degree of noxious air is removed by the fanners stationed at the mouth of the hive, there is, I conceive a much deeper philosophy connected with this development of instinct than a casual observer would suppose. Is there no appreciation here of the chemical doctrine of "gaseous diffusion," by which gases of different densities intermingle, even when the denser is the lower? The movement of the living fans imparts momentum and directive force to atoms of air already in a state of natural commotion. The instinct of the bee has from the beginning laid hold of a chemical law which natural science only discovered in the last generation. "*Magna opera Jehovæ exposita omnibus qui delectantur illis.*"

I had intended to cite some curious illustrations of aparian observation and experience which my recent correspondence has most amusingly and instinctively brought to light, but I have already occupied your space too fully. I must reserve this until I have something to say about the "Ligurian bees," which I have just introduced into my apiary, and conclude with two or three observations about bee-flowers and honey. In early spring the great requirement is pollen, and the indication of a populous and prosperous hive is afforded by the eagerness with which it is sought. Bees revel among willows, and in a bed of osiers they find an ample storehouse of spring provision. Of course they ransack the nectaries of all early flowers, and the leaves of the laurel and the ivy also afford them very grateful supplies. Those of the former are punctured in the very early spring

by a solitary *aphis*, and if closely examined will be found to contain an exudation of a transparent gummy character, viscous and saccharine. The puncture is generally found on the under side of the leaf, in the cuticle, about an inch from the petiole or stalk. It requires very close examination to discover it, although I have occasionally seen its honey drop the size of a No. 4 shot. I have no doubt it is excretory. But I must not forget to mention one flower, an early summer one, which from the extraordinary fondness bees evince for it, we call here, by way of pre-eminence, the "bee-flower." It is a salvia (*S. nemorosa*), and for gardens large enough for massing different colours is really no mean acquisition. The leaves are glaucous, and the flowers a deep lavender. It flowers early in June and continues all the summer. I will send you a dozen roots with pleasure. I must not say all that I thought of doing respecting the nature and origin of some of the materials from which honey is elaborated. Chemistry can change old rags into sugar, which would be none the less palatable because of its origin, were it not that fancy sometimes affects the taste.

Let us think, then, of "busy bees" only in connection with sweet spring flowers and sweeter honey, and not allow science to vitiate our taste. "Where ignorance is bliss 'tis folly to be wise."—WILLIAM LAW, Marston Trussell Rectory, Theddington, Rugby.

RECOLLECTIONS OF AN OLD FANCIER.

No. 4.—TRADESMEN FANCIERS.

I READILY, gladly, even proudly, own to have a great liking for the sons of trade. I like them whether they belong to High Street, or Back Lane. I know them well, and have been fellow-workman with them in carrying out many a literary scheme. I have found, especially among the younger men, a thirst for knowledge, and sometimes an extent of reading which would surprise many who have never come mind to mind in contact with them, and still more surprising when one considers the very few hours a-week they are able to devote to literature. Much kindness extending over many years have I received from tradesmen; and when I hear fine ladies and gentlemen complain of having met with incivility from behind a counter, I have thought, almost said, "Have you, sir, been quite the gentleman, or you, madam, quite the lady to those of whom you complain? Have you been civil, or only haughty? Have you felt there was the same blood in the one that handed you an article of dress, or showed you a book, as in yourself—that they were your fellow creatures and fellow Christians? Have you been kind, and spoken in a tone of voice which showed you respected the feelings of others? If you cannot say on your conscience that you have done all this, need you wonder as to what you have met with, taking poor human nature as it is?"

Now, the industrious tradesman, who looks well after his business, has naturally a very stationary position; he must be a keeper at home, he cannot leave his duties; in plainer words, he must "stick to the shop." But such a man so situated, needs above all men, a hobby, yea, I am sure *all* men need one; a little outlet to certain feelings almost indescribable, something which is to the man what a toy is to a child. "We should cultivate the pleasure gardens of our minds as well as the corn fields," said Archbishop Whately. Wise, beautiful words! The man who has no innocent hobby is apt to make vice his hobby.

But, in regard to tradesmen, they must not have a hobby which, by taking them from home, removes them from positive duties—which, in fact, would interfere with their providing for their families. Thus horses are always dangerous if made a hobby of. Oh! the many "horsey" tradesmen that I have known come to ruin. Horses lead to hunting, then hunting to absence from home. Even a professional man is sometimes injured in this way. I knew a surgeon who soothed his conscience as to hunting by saying of the master of the pack, "If Lord So-and-so should have a fall and break his collar bone, it would be the making of me." However, my lord never fell and broke a bone, but the doctor's patients fell off instead, calling in another surgeon during his absence.

Worse than hunting, far worse (and I wish to say ever a word to do good as well as to amuse or instruct), is racing, as

that involves gambling. A tradesman, owner of a racing pony, known to me in early days, ended his career a suicide in a county jail.

Well, then, having settled it that an industrious, careful tradesman ought not to be away from home in business hours, where may he find a suitable hobby? And, in passing, let me add, that in these days of much travelling and sightseeing, home pleasures are apt to be despised. Our truest, our best pleasures are at home, easy of access, close to us—like the daisies they lie very near, if we will but look for them.

In what, then, I ask, may the man, much by necessity and duty at home, find an innocent hobby? First, in flowers, and especially in florists' flowers. These are better as a hobby than a general garden, for they require such constant looking after, and like children, care of them increases our love. "People talk of a proper pride, sir, you might as well talk of a proper dunghill," said a stern divine of old days; but he was wrong, quite wrong. There may be a proper pride: thus a man may have a proper pride in his flowers. How well do I remember the pride, yes proper pride, with which a grocer showed me his bed of Ranunculus. There, under an awning, carefully tended, were the glorious flowers, glowing, bright, and beautiful, the result of days and weeks of care.

Then, is there not a proper pride when a prize has been won? Before exhibition-day what family consultations there are, why the whole household is concerned in the matter—"Shall it be this flower or that?"—and the pride of all when the prize is brought home! I once found a schoolmaster whose hobby was his orchard-house, garden he could have none, for that was all playground; but on the little space to spare he built an orchard-house, and there he forgot his woes, the boys' noise, and the false quantities and bad syntax.

But not only flowers, there are birds, fowls, pigeons, and rabbits, all these prove excellent and harmless hobbies. The eye of Crabbe, a town-bred man like myself, saw the use of hobbies, and what they were. After describing a small tradesman's family, he says—

"True pleasure hails them from some favourite source,
And health, amusement, children, wife, or friend,
With life's dull views their consolations blend.
Nor these alone possess the lenient power
Of soothing life in the desponding hour.
Some favourite studies, some delightful care,
The mind with trouble and distresses share;
And by a coin, a flower, a verse, a boat,
The stagnant spirits have been set afloat;
They pleased at first, and then the habit grew."

"Oft have I smiled the happy pride to see
Of humble tradesmen in their evening glee,
When of some pleasing, fancied good possessed,
Each grew alert, was busy, and was blessed.
Whether the call bird yield the hour's delight,
Or, magnified in microscope, the mite,
Or whether *Tumblers*, *Croppers*, *Carriers* seize
The gentle mind, they rule it and they please."

Fowls Crabbe does not mention, though he well might; for into how many a backyard have I gone to see them—how many a cockloft have I climbed into to see Pigeons—how many an outhouse to examine the wondrous ears of some prize Rabbit; or stood in the little walled garden to watch the habits, or hear narrated to me, of now a Hawk, and then a Plover!

As to the benefit derived from a hobby, of that, as well as the pleasure afforded, I am quite confident. A hobby is a relief to the mind, it employs some of its loose faculties. Yea, it promotes good temper, soothes a ruffled spirit. A brief run from the ledger to look at fowls or flowers is refreshing.

Then a man's little plans for the improvement of his birds, his pleasant intercourse with other fanciers. I own that I think live things are better for hobbies than anything else. A man may become tired of collecting stamps, or of autographs, but rarely will he tire of birds. A bishop was accustomed to get up and say, after a hard day's work in his library, "Now, then, I will go and have a look at my pigs;" and a witty friend of mine declares of a super-Calvinistic divine, that it was wonderful how less terrific his opinions became after he took to Cochins.

So I say, let every man have his hobby, and he will be the better for it, so long as he rides it, and it does not run away with him. And further, let every man whose duty makes

him stay at home, have a home hobby, and it will bring him no injury—not the hunter, nor the racehorse, but rather the florists' flower, or the bird, the fowl, the Pigeon, or even the despised Rabbit. High Street may have some of the former, Back Lane some of the latter.—WILTSHIRE RECTOR.

OUR LETTER BOX.

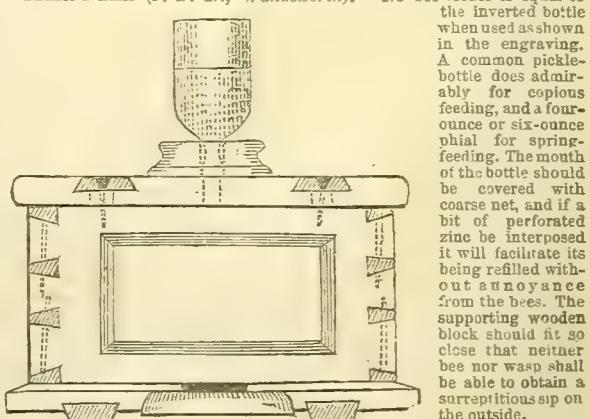

"Y. B. A. Z."—We have a letter for this correspondent—whether shall it be directed?

LACED FANTAIL PIGEONS (*A. P. L.*).—If Lace Fantails could be produced of equally good carriage, and with as ample tails as the common Fantail, they would compete well in a general class for this beautiful variety of Pigeon, but as yet none have been publicly exhibited at all equal to the usual White Fantails in these most essential peculiarities. If a pen of Lace Fantails were equally good, we believe that almost every one of our principal Pigeon arbitrators would decide in their favour, simply in recognition of their peculiar feather and comparative scarcity; but the birds hitherto shown were decidedly open to great improvement before they could claim an approach to equality with our best Fantails. It is quite impossible, nevertheless, to give any opinion on birds we have not seen.

TAXES' BEE-MASTER.—We have received various communications—some attacking and some defending him; but we think it best to occupy no more space concerning so unworthy a book. The line of defence adopted is, that though the book is very faulty, yet errors are to be found in other works on bee-management, which is no more a defence than was the excuse offered for a bad picture—"Yes, it is bad; but Jones painted a worse."

BEGINNING BEE-KEEPING (*E. C.*).—We should recommend your beginning with flat-topped straw hives, such as are described in "Bee-keeping for the Many," under the name of "Payne's Improved Cottage Hive," but made rather larger—16 inches diameter inside, by 8 or 9 inches deep, is a good size. These hives have a central aperture in the top, 4 inches in diameter, over which is placed a small super, which is not, however, intended to prevent swarming. If you wish to adopt the depriving system you may have straw hives made after the pattern described by Mr. Woodbury in his paper on bee-keeping, which appeared in the "Journal" of the Bath and West of England Agricultural Society. Mr. Woodbury says—"Stock-hives may be 16 inches in diameter by 9 deep, inside. As a flat-top of this size, when made of straw, is apt to sink with the weight of the combs, it may be formed of two circular pieces of half-inch wood, glued and nailed together, with the grain crossed, to prevent warping. There should be a two-inch central aperture for feeding, and two slits, half an inch wide, by 6 inches long, on either side, and a sneer to the sides of the hive as possible. The two-inch hole should be closed by a bit of tin or zinc when the bees are admitted into a super through the side apertures, as the queen is apt to lay eggs in the super when central communication is permitted. When not in use all egress through these apertures is stopped by means of wooden blocks." Either of these hives will enable you to commence bee-keeping economically, conveniently, and profitably. Whenever you wish to step beyond them we advise you to go at once to Woodbury frame-hives, of which you will find a working description, with illustrations, in "Bee-keeping for the Many." Frame-hives have become almost universal in America, and they present so many advantages that we cannot but believe they will rapidly supersede all others in the apiaries of such of our British bee-keepers as aim at something beyond the old-fashioned straw hive and brimstone-pit.

FEEDING BEES (*J. F. N., Wandsworth*).—No bee-feeder is equal to the inverted bottle when used as shown in the engraving. A common pickle-bottle does admirably for copious feeding, and a four-ounce or six-ounce phial for spring-feeding. The mouth of the bottle should be covered with coarse net, and if a bit of perforated zinc be interposed it will facilitate its being refilled without annoyance from the bees. The supporting wooden block should fit so close that neither bee nor wasp shall be able to obtain a surreptitious sip on the outside.

DR. CUMMING'S BEE LECTURE (*A Constant Reader*).—We did not notice the lecturer saying that Virgil gives an account of bees in one of his "Eclogues," instead of "Georgics," because this was not a mistake from ignorance. Dr. Cumming is not without classical knowledge.

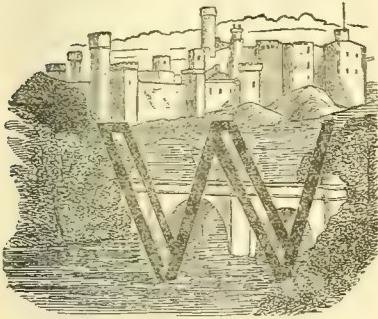

TOMATO SAUCE.—Mrs. G. Dowdeswell, seeing a wish expressed in the last Number for a recipe for making tomato sauce, begs to mention a very simple mode adopted by herself for some few years past, by which she can have the same prepared by the cook as required, fresh at any time. The tomatoes are gathered perfectly ripe, free from cracks or bruises, and are gently wiped with a soft cloth, and placed in a wide-mouthed jar. Some vinegar, having been boiled and allowed to stand until cold, is then poured over them, sufficient being used to entirely cover them. The jar is then covered with wetted bladder, and the tomatoes keep perfectly fresh and good until those of the following season come in. The peasantry in the south of France keep the tomatoes in this simple manner. Their mode of making sauce Mrs. Dowdeswell, unfortunately, has not perfectly; but the tomatoes, in the manner described, can be made as required into sauce by any cook.—*The Down House, Worcestershire.*

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 50.2°, and its night temperature 34.8°. The greatest heat was 63° on the 12th, 1841; and the lowest cold, 13°, on the 9th, 1854. The greatest fall of rain was 1.24 inch.

BEDDING FOR WINTER AND SPRING.

HAT a splendid season! we hear expressed upon all occasions when we come in contact with either town or country gardeners; and so it has been. Surely we may venture to say that the Italian summer has been

equalled for once by that now passed away in Britain.

Among the other wonders this has wrought none are more conspicuous than the gorgeous continued display of colours which all who have a flower garden must have enjoyed up to a much later period of the season than most can remember. A majority of our flower-beds were full, and in fine order until the rather sharp frost on the morning of the 24th of October. This had the effect of putting most people on the alert, who had their tender or valued sorts of bedding stuff still out.

It might by many parties be considered that this late continuance of flowering, in comparison to other seasons, would be a hindrance to the planting of winter and spring bedding stuff. This is not so, but very much in its favour. If such things as Pansies, Silene, Myosotis, Stocks, &c., be planted in their winter quarters early, and we have a good amount of sun afterwards, they invariably commence growing fast, and are, therefore, tender when the sharp winter frosts begin. Silene is, perhaps, the most difficult to get in at the proper stage. This season, however, we have overcome that most effectually. Upon observing that the fine weather was bringing these plants too forward, I set a man with a fork to raise the plants quite up, and then tread them in again; we have repeated this until they are starved but sturdy-looking plants, and likely to meet any frost without injury. Nothing makes such splendid spring beds as the Silene pendula, both white and red.

The beds and borders filled up to this time consist of one bed of dark Auricula, edging Arabis lucida variegata; yellow Auricula, edging of the same Arabis; Polyanthus black, red, yellow, and variegated, with Crocus edgings; white Pansy with blue Scilla edging; Magpie Pansy, with Dog's-tooth Violet edging; yellow Alyssum, with dark red Daisy edging; white Evergreen Candytuft, with blue Pansy edging. All these are crammed quite full, not an inch of soil to be seen; our stock allows us to do this; for although the season has been dry, and it was consequently difficult to manage these plants, every one was kept in some shady place with only a sparing amount of water.

The smaller borders we are now (October 28th), busy No. 189.—VOL. VII. NEW SERIES.

digging what we term spit and a half. This allows us to give a good dressing, and also to take up the bulbs left in the border over the summer. These are arranged and planted again as the work proceeds, planting the bulbs in rows or otherwise on the top of the first-turned-down spit.—J. F., Cliveden.

(To be continued.)

VINES FOR THE ORCHARD-HOUSE.

ARE you ever asked to recommend Vines for an orchard-house? If so, be sure to place Trentham Black the first on your list.

In one large orchard-house which covers 300 square yards I planted a Vine to each of the pillars, to see if good Grapes could be grown in Nottinghamshire without heat. The only ones I had much faith in were the white and rose-coloured Muscadines, though I hoped the Black Hamburg might ripen; but to prove them I planted several other varieties. The result is that the Muscadines have been ripe and cut long ago. Chasselas Vibert has also been dead ripe some time, but is not worth growing, being too small and shabby-looking, though good in flavour; the bunches and berries are only about half the size of the White Muscadine.

The Black Hamburgs are good in colour, thin-skinned, and in flavour quite equal to those grown in heat, though not quite so large. The Trentham Black is, however, quite the best, being richer, larger, and blacker than the Hamburgs, and in every way superior. In the hot-house the Trentham Black is a first-rate early Grape, we cut about 40 lbs. from a young Vine this season; but it would not be wise to plant too many of this variety in our early house, as it is too thin-skinned to keep long after it is ripe. With us it is earlier, larger, and richer than any of the Hamburgs, and all persons would do well, I think, to plant one of this kind; but as a variety to be grown in a cool or cold house there can be few or none equal to it.

We really cannot be too careful in recommending fruit trees; it is so tiresome, after waiting years, to find it necessary to replace a worthless variety. I called a short time since at Frogmore, and as the Prolific Muscat, raised in that garden, will hardly grow with me, I asked to see it in fruit, and was told it had been destroyed as worthless! What will those say who have given from one to two guineas a plant for it, and that so recently?—J. R. PEARSON, Chilwell.

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 3.

THROUGH the Trossachs—not walking or driving leisurely, stopping here and there to admire, now dragging this wheel, now getting down for a lounge up that hill;—but dashing, scrambling, tearing along on the outside of a rickety old coach, driven unicorn fashion, with a wild-looking “leader,” having a mad devil in

No. 841.—VOL. XXXII., OLD SERIES.

her eye, called "Black Bess" by the coachman, who, instead of minding his horses, kept quoting Sir Walter Scott, to the intense horror of one of our party, a superb four-in-hand "whip."

Oh! the perils of that drive—the ludicrous mixture of the sublime and the ridiculous. Black Bess scorned a whip, and the coachman employed his to illustrate his quotations. "There, madam, is the rock where Fitz James withstood Roderick Dhu."

"His back against a rock he bore,
And firmly placed his foot before."

Hold in, Bess, will you; what's up now?" "My good friend," broke in the whip, "do let me have the reins. Do, pray, be careful." "Bless you, sir, don't be frightened, Bess is as gentle as a lamb when you let her have her own way. Hold hard, old girl. Now for it;" and like a mad thing, Bess was tearing down a grip, and pulling might and main up a steep ascent.

A few more alarming quotations and we come to Loch Katrine, lying graceful and beaming, with its little sunny isles beneath the shadow of its mountains and its trees.

A small steamer plies up and down this lovely lake, and you find yourself looking out for landmarks given you by Scott. The "beach of pebble bright as snow," the "silver strand" are there, it only needs "fair Ellen's" voice to take the place of the rough music of the paddles.

Loch Katrine is a graceful preparation for the grander beauty of Loch Lomond. I can hardly fancy a lovelier picture than that which bursts upon you as you near the inn of Inversnaid, Ben after Ben rising in the distance, some brown, some blue, and some with bright patches of green here and there.

I did not forget the Ferns. I spent hours hunting the hill-sides at Inversnaid. Oreopteris grew in abundance, with beautiful *Filix-femina* and other common Ferns. I had made friends on the lake with a gentleman, armed as I was with trowel and bag. He joined us in the walk.

"What success?" I asked, half hoping he had found some rarity, half fearing lest his booty should exceed my own. He shook his head. I opened my store triumphantly. "Look here," I said, "is not this a wonderful find?" and I displayed a graceful little Fern. "This is the *Woodswia ilvensis*!"

I saw a twinkle in the "Fern-man's" eye; but he told me gravely my specimen was only a baby "*Flix-femina*;" and then he added, how troublesome baby Ferns always were, and that one could not easily decide on a Fern unless there was fructification. I might hunt for varieties of *Filix-mas* and *femina*, but he thought I should find nothing else. Then he discoursed of Ferns in general and of Fern-hunters, how he found ladies looking for *Septentrionale* in a wood, for *Ceterach* in a ditch, and for *Asplenium viride* on a wall. "I do," said I.

"It is a pity to waste time," he answered. "Find out the whereabouts before you search. Know what you are likely to find, and then take anything strange you meet with." And so it came to pass I only brought away from Inversnaid a few young plants of Oreopteris and a *Lycopodium* or two; but I took to more diligent readings of Moore, and wished there had been a few simple directions as to the "how" of finding Ferns.

Of course we made the tour of Loch Lomond in the steamer, which was filled with a strange mass of human beings bent on pleasure—the geologist with his hammer, the young girl with her sketch-book, the botanist with a round tin at his back, the pedestrian with his knapsack. For five minutes we scanned each other, and then turned our attention to the scenery. It was a glorious day—a day of strongest lights and shadows—a day of sun and cloud; and I could scarce fancy any luxury greater than lying down on a sofa of plaids and sailing through this beautiful world of waters—a world cut off, as it seemed to be, from any outer world by high frowning mountains, by steep shaggy rocks—every minute the scene changing, bold rugged Bens melting away into bright green islands, and these into a far-off distance of more gentle outline. Looking from side to side as you approach Inverarnon, you come to a hill covered with Firs, some standing, many fallen, and already "barked." A picturesque group of women in red petticoats and white jackets are seated by a picnic fire cooking; these

are the 'barkers,' who live in rough huts built about the wood during their season of work, and vividly remind one of the Olive gatherers in the Olive woods of Sardinia.

From the head of Loch Lomond a coach conveys you over the Black Mountain and through the awful pass of Glencoe to the hotel of Banavie at the foot of Ben Nevis, where I was assured I should undoubtedly find *Polystichum lonchitis*; and up the sides I tramped many a weary mile in the search, now scrambling up a rocky path, now floundering in a bog—but no lonchitis. Indeed, I may here own that I have never found one plant of this most interesting Fern. "*Lonchitidoides*" I have found in plenty, and some bearing such close resemblance to lonchitis as for a time to create a doubt even in the mind of Mr. Bree; but the doubt cannot last very long, for I have proved the fact that lonchitidoides in time becomes lobatum, and after a while lobatum becomes *P. aculeatum*. I have watched the plants changing from year to year, and have had many an argument about it; but each Fern-grower can prove it for himself in three or four years.

I have one large plant of true lonchitis, which I bought at a small nursery without being able to trace its history, and from which I have this autumn divided three young plants. There is one feature in lonchitis which entirely divides it from lonchitidoides—the pinnules, even in the tiniest frond, lap over each other like the scales on a fish's back; each pinnule is furnished with sharp teeth, with a projection like an ear close to the rachis, which is covered with brown scales; the fronds grow stiff and erect, and its whole formation gives one the idea of protection from wet. The fronds spring from the centre, throwing up several sets of fronds during the summer, the whole preserving a compact vase-like form. During the extreme heat of summer, after watering the Ferns I made a practice of pouring a little water into the cup of the plant, thinking to encourage the new fronds. After some time I observed a little frond quite perfect, yet very small, spread itself like a guard over the nest of young fronds. I gave up my system of encouragement, and, instead, threw a little cocoa-nut refuse into the centre of the cup as a protection; and this has answered beautifully, and the plant has thirty fronds on it of this year's growth, but the long-continued drought has caused these to be less fine than usual.

In the wooded dells at the foot of Ben Nevis I found the Pyrola, whose pretty bell-like blossoms of white with a rosy flush were as fragrant as a bowl of Lilies of the Valley. I brought several plants away, but failed to make them grow.

My next hunting ground was Oban and its neighbourhood; and here I had great success with *Cystopteris fragilis*, which abounds in many beautiful varieties. On the road to the Kerrara Ferry I found *angustata*, with its acutely drawn-out length of frond and pinnae; *dentata*, broad and stumpy-looking, bearing a near resemblance to *Dickieana*, save that the fronds are more robust and the pinnae not quite so closely approaching each other. I have never found *C. alpina*, *C. montana*, or *Dickieana*; but I possess many healthy plants of each variety excepting *montana*, which I have lately procured from Mr. Veitch's nursery. It promises to grow rapidly as the others do, but I daresay it will need a little extra care.

The walk from Oban to the Ferry will repay the tourist, even if he be not a lover of Ferns. Amongst the heather he will find the Golden Asphodel with its feathery blossoms of exquisite form; and in July there are beds of rich ripe Strawberries scenting the air, which blows pure and fresh around him. He should go at eventide and watch the sun setting over one of Nature's loveliest scenes. The sea, broken into numerous still calm lakes by rocky islands, reflects every golden cloud, while the distant mountains form a frame of the softest blue; and above and beneath, it is the same fair scene.

Oban is a real Scotch town—you feel you are in the Highlands. The people talk a *patois* of English-Gaelic, and understand you with difficulty; the shopkeepers have an English of their own. It is a strange isolated community grafting English fashions slowly on northern stocks.

You go to a "store" to buy calico or some little matter. "Have you any good calico?" you ask. "Yes—no—I think—my calico is worth hardly anything just. Yes, it's very

bad calico." Perhaps you are obliged to have it, and, to your surprise, find it very dear. You remonstrate. "Yes, I think it's very dear calico, and no good in it," they answer.

Then their good nature is wonderful. They will know your business, and will insist upon trying to help you.

In a country walk you pass by what looks like a huge washhouse. "Is that a washhouse?" you ask a poor woman in the road. "A washhouse, is it? Yes, I think. Is it a washerwoman you want? Allow me to recommend you one; it's Mistress McFarlane, of Tweedle Street; she's just the most perteeeklar woman in fine linen and dressing."

Staffa and Iona are "done" from Oban, but it was just afraid of the water I was; so I watched the departing and returning steamer in peace, picturing to myself the damp beauty of Fingal's Cave; the ruined cathedral standing out against the clear blue sky; and wondering what Columba would have said to the Free Kirk in Scotland, and whether any Ferns grew upon the weather-beaten island.

I spent a day on Kerrara, hunting in vain; but it is not time wasted, for the shores of the island are very beautiful, and the slopes green and sunny, and many a lesson of life may be learned while listening to the quiet music of the waves breaking against the shore.—*FILIX-FEMINA.*

DECORATION OF THE FLOWER GARDEN IN WINTER AND SPRING.

(Continued from page 346.)

FLOWERING AND VARIEGATED PLANTS.

EARLY spring-flowering plants are, as the following lists of those most suitable for planting in masses will show, pretty numerous, furnishing materials for a fine display from the blooming of the delicately-tinted Christmas Rose till the gorgeous queen of flowers herself comes forth. Such plants offer almost every shade of colour in their bloom, diversity of form, habit, and foliage, this in many cases being variegated, or otherwise ornamental. Thus the flower-gardener, who is possessed of taste, energy, and intelligence, has at his disposal materials which will enable him to make no inconsiderable display during the early spring, spring, and early summer months. Numerous, however, as the materials are now, there is every probability that when a taste has been disseminated a greater demand will arise, and more will be forthcoming.

As a rule the tints of flowers are lighter during the cooler portion of the year. In spring we have an endless variety of white flowers; summer abounds more in scarlets and reds; and autumn in yellows and purples. In a gardening point of view man very much alters the natural distribution of the colours, and the garden is made to teem with scarlet in autumn, and this tells well on account of the preponderance of green at that time.

Spring-flowering plants may be divided into five sections, according to the colour of the flowers and foliage—viz., 1st, Whites, including those with silvery foliage or white variegation; 2nd, Blues; 3rd, Yellows, including those with golden variegation; 4th, Purples; and 5th, Reds, including reddish-purples.

1ST.—WHITE SPRING-FLOWERING PLANTS.

Of these the most interesting and beautiful is the Christmas Rose (*Helleborus niger*). It attains a height of about 1 foot, and is well adapted for a centre to a bed of bright colours on account of the bright green of its foliage, which forms an excellent neuter, whilst the flowers are most interesting, especially when peering from beneath a bed of snow. It will grow anywhere, but prefers a rich light soil, with occasional applications of leaf mould. It is increased by division of the root.

Arabis alpina, *albida*, *grandiflora*, and *lucida*, are well-known profuse bloomers, forming a close carpet of whitish foliage. Being of dwarf growth they are well adapted for low beds and ribbon-planting. *A. albida variegata*, with white variegation, is admirably adapted for edgings. All are most readily increased by division. Small portions put in 6 inches apart in nursery-beds in spring, after blooming, will make fine plants by autumn, and may then be moved with balls to the places assigned to them in the flower garden.

Hepatica triloba alba, or white *Hepatica*, is lovely, not growing more than a few inches in height. I have seen many so-called double white Hepaticas, which were only dwarf double Wood Anemones.

Saxifraga oppositifolia alba is most charming; the bed should be surfaced with small rock stones or clinkers, and the interstices filled with sandy loam and peat in equal parts, in which the plants are to be planted. *Saxifrages* of all kinds require the same treatment—viz., to be placed on raised beds of rockwork, clinkers, brick, or even flint, and after filling the interstices with soil they should be planted thickly, so as to cover the surface. They then form pleasing beds.

Stellaria holostea is nothing more than a weed in our woods; but a very pretty weed it is, flowering abundantly in ordinary light soils from March to June. It is increased by division of the root after flowering; and the divisions, planted in nursery-beds, make fine roots for moving to the beds in autumn.

Linaria cymbalaria alba is a pretty trailing plant 3 or 4 inches high, and makes a lovely edging or bed if treated in the same way as the *Saxifrages*. The variegated form is also fine on account of its foliage. It requires a sandy loam, and is increased by division or rooted stems.

The next plant worthy of notice is *Mentha sylvestris variegata*, the merit of which consists in its foliage: hence it is useful for edgings and line work. It is increased by cuttings and division.

Phlox Nelsoni, than which nothing is handsomer, should be planted on raised beds, as described for *Saxifraga oppositifolia*, as it is impatient of stagnant moisture. It likes a sandy soil, and seems all the better of a little peat. Cuttings and division. *Phlox nivalis* is a fine free-blooming sort, not exceeding 6 inches in height. It does best in raised beds, and is benefited by a little sandy peat. It was, and I believe is, scarce in gardens.

Of *Bellis perennis* there are many fine double varieties. They are of most easy culture, it being only necessary to divide the roots. They are fine edging plants. Light sandy soil is best.

Lamium maculatum (longiflorum) album is another pretty weed of our own hedges, flowering in March and onwards; growing freely in common soil, and readily increased by division. It grows about 1 foot high, and is very fine when well grown.

Primula nivea, *vulgaris alba*, the double form of the first species, and *Primula vulgaris alba plena*, are well known, and amongst the handsomest of spring flowers. The white Cowslip (*P. veris alba*) is also pretty. Division.

Ranunculus amplexicaulis, from the Pyrenees, grows about a foot high, and makes a fine bed. It will grow anywhere in an open situation, and in common soil. It is increased by division.

Isopyrum thalictroides is a pretty white and green flowering plant, attaining a height of 9 inches, and flourishing in sandy loam. Division.

Iberis sempervirens, *saxatilis*, *corifolia*, *Tenoreana*, and *gibraltarica*, are fine evergreen under-shrubs, attaining a height of from 6 to 12 inches, and flowering so profusely as to be sheets of snowy white in April and onwards. They will grow in any kind of soil, but bloom earlier in that which is light and sandy. They are most readily propagated by cuttings.

Trillium grandiflorum, a tuberous-rooted plant, is a charming thing not much more than 6 inches high, delighting in sandy soil, and doing best of all in sandy peat. Increased by parting the roots.

Iris pumila alba and *I. sibirica alba* are very neat dwarf plants, flowering in March and April; effective in groups. Division.

Arenaria balearica is a very pretty trailer, and not less so is *A. ciliata*. They are increased by division, require light soil, and are always improved by a little peat.

Ficaria ranunculoides alba is all but a yellow. It is a pretty little plant, growing about 6 inches high, has tuberous roots, and is increased by division. *A. montana* we must also have.

Antennaria margaritacea is a splendid white-foliaged plant, suitable for forming a band, line, or edging, a foot wide and the same high. The young shoots rise from the stool, and are as white as snow, in April, when the plant may be in

creased by slips like Sage, each slip having an inch or two of the root-stem attached. It makes a splendid row or ribbon all through the summer, and it flowers so well from June to September as to be valuable for bedding purposes; but being in every cottage garden, and as hardy as the Nettle, no one cares about it.

Asperula odorata (Woodroof), a common plant of our woods, flowering in May and onwards, is a fine thing as everybody knows. It grows about 9 inches high, has white sweet-scented flowers, likes a sandy soil, and is increased by division. *A. taurina*, from Italy, is a suitable companion to the English Woodroof, and a very pretty plant. It is increased by division.

Dodecatheon meadia albiflorum is a very pretty American Cowslip, growing freely in loam, attaining the height of a foot, and increased by division.

What is handsomer than our Cloudberry (*Rubus chamaemorus*), so dwarf and altogether lovely? It grows freely from suckers in loam, and better still if a little peat be added. *R. saxatilis*, too, is no mean ornament, but its blooming is a little too late, not being general till June, otherwise it is a dwarf trailer with few rivals.

Again, there is the lovely *Cochlearia integrifolia*, *fenes-trata*, *pyrenaica*, *officinalis minor*, and its sub-variety *rotundifolia*, all white-flowered biennials, growing 3 or 4 inches high, and all alike fine.

Cardamine pratensis flore pleno, which has dirty-white flowers, just comes to mind as being suitable for those who may strive to find an excuse for the emptiness of their flower-beds on account of the wetness of the soil. This is the plant for such. *C. bellidifolia* will suit places at a high elevation, like Ben Nevis on the other side of the Tweed, whilst those situated on low ground will find *C. trifolia* useful. Division.

The *Hutchinsia calycina* and *H. alpina* are nice things, the former a mere pygmy of about 2 inches, fond of sandy peat soil; and the other 4 inches high, and growing anywhere in common soil; both are increased by division.

Glaux maritima alba is a pretty trailer, growing freely in sandy soil, and attaining a height of 3 or 4 inches. It is best raised from seed, and is also increased by division.

Androsace villosa, with dirty-white flowers, and *A. chamae-jasme*, dirtier still, are nevertheless very pretty; but though occasionally flowering early, are not to be depended on. Sandy peat is the best soil for them. Increased by division.

Jeffersonia diphylla is a pretty plant, doing well in sandy loam. It is increased by division.

Corema alba, an under-shrub about a foot high, is, beyond dispute, fine; though its flowers are not of the gayest, yet it is handsome, and has white berries afterwards. Requires sandy peat, and is increased by layers.

Prunella vulgaris alba, a native plant, is curious, rather precarious as to time of blooming, but as it does occasionally bloom early we must have it, and divide the roots to obtain a stock.

Cornus suecica, from the Scotch and Swedish hills, we must also lay hands on, and grow in bog soil, dividing the roots for stock.

Violas asarifolia, *humilis* (a little Mexican, only hardy in sheltered situations), *odorata alba*, *odorata alba plena* (once common enough, but now scarce), *canadensis*, *bicolor*, *attenuata*, and the white Dog Violet (*V. canina alba*), are all white Violets more without than with scent; they are all increased by division.

Pulmonaria officinalis alba is really ornamental, and grows anywhere. It is about a foot high, and is propagated by dividing the roots.

Schizereckia podolica is all but an Alyssum, and fine. It should be grown in light soil, and will do better in peat. Division.

Silene patula and some others, flower pretty early occasionally, but generally not before June.

Cerastium tomentosum, *alpinum*, *lanatum* (will make its way into a ribbon ere long), *latifolium*, *grandiflorum*, *Biebersteini*, and *glaciale*, the first and the last but one well-known ribbon plants, to which others may be added as rivals, especially *C. grandiflorum*. Division.

Besides *Cerastiums* we must have others on account of their foliage:—*Funkia Sieboldi variegata*, *Fragaria vesca variegata*, and *Vinca major variegata*, and to these may be added

more flowering plants, as *Saxifraga nivalis*, *pyramidalis*, *intermedia*, *longifolia*, *longifolia media*, *polita*, *tridentata*, *affinis*, *petraea*, *elongella*, *hypnoides* and its varieties *pulchella*, *viscosa*, *muscosa*, and *angustifolia*, and last of all *Stachys lanata*.

2ND.—BLUE SPRING-FLOWERING PLANTS.

Hepatica triloba cerulea and its variety *plena* (single and double blue Hepaticas), are amongst the earliest and handsomest, and why not grow *H. angulosa*, *acutiloba*, and *americana*? They are fine, but little different in appearance, I mean in flowers, from the commonly cultivated varieties. Division.

Aubrietia deltoidea, *purpurea*, and *A. deltoidea grandiflora* not only flower profusely in spring, but are in fine bloom now (October 24th), and will continue so throughout the winter. Divided in spring like *Arabis*, and grown in nursery-beds, they make fine plants by autumn.

Aster alpinus purpureus is a pretty dwarf species attaining a height of 9 inches. It likes light soil with leaf mould or peat. Division.

Campanula excisa and *gracilis*, are fine, and are increased by division.

Borage orientalis, *laxiflora*, and *cretica*, are fine free-blooming plants, the first attaining a height of from 18 inches to 2 feet, and the last two about a foot. They do best in sandy loam. The first is increased by division, and the last two by cuttings.

Ajuga reptans cerulea, and the variegated form of *A. reptans*, are nice, not growing more than 6 inches high. Division.

Omphalodes verna is an elegant plant, not above 6 inches high, and makes a nice bed. It likes a light soil, and is increased by division.

Glechoma hederacea, a weed in almost every hedge, has lovely blue flowers in spring, and can be had in any quantity for the trouble of collecting. It is propagated by dividing the roots, or putting in cuttings of the rooted stems.

Geranium pratense, an elegant weed in many meadows, and its double variety (*G. pratense flore pleno*) from the Scotch mountains, would be considerably enhanced in value if they could only be induced to flower a little earlier; as it is they are useful. A stock is obtained by dividing the roots.

Globularia vulgaris, and *linifolia*, are pretty plants, growing about 6 inches high, the former propagated by division, and the other by cuttings.

Soldanella alpina, *montana*, and *crenata*. Very pretty plants, forming fine beds. They must have extra drainage and free soil, with a little leaf mould or peat. Division.

Polemonium reptans makes a nice bed, and will grow anywhere. Division. Height about 6 inches.

Lithospermum prostratum is a pretty trailing plant, attaining a height of about 1 foot. Propagated by cuttings.

Anchusa stylosa, *myosotidiflora*, growing about a foot high, and *A. paniculata*, a tall species, are fine Borage-like plants. The last is raised from cuttings; *stylosa*, though an annual, should be treated as a late-sown biennial, and be sown in autumn; the Forget-me-not-like species (*A. myosotidiflora*) is increased by division.

Above all, we must have *Gentiana verna*, *acaulis*, and its narrow-leaved variety (*angustifolia*); *G. pumila*, *pyrenaica*, *brachyphylla*, *humilis*, from the Caucasus, though it is an annual, and must be sown every year in September, and then add *G. altaica*, a taller species by three-fourths than any of the others. We may obtain them in any quantity by dividing the roots. Well drained soil and leaf mould or peat are essential.

Sisyrinchium grandiflorum is a pretty thing, requiring light soil, and is increased by division.

Pulmonaria azurea is well worthy of cultivation. *P. mollis*, and *P. angustifolia*, though native species, are fine; and *P. paniculata*, and *virginica*, I have booked for a prominent position. Division.

Phyteuma paniculiflorum (not so few-flowered as the name implies), *P. Halleri*, and *P. Sieberi* are pretty. They are increased by division, and grow but a few inches high, except *P. Sieberi*, which attains about 1 foot in height.

Erinus alpinus forms a fine bed, not more than 3 or 4 inches high, and does all the better if grown in light, dry soil. Division.

Veronicas petraea, *prostrata*, *aphylla*, *microphylla*, de-

pauperata, serpyllifolia, tenella, nummularia, neglecta, and quaternata, are all lovely little plants not more than a couple of inches high; alpina in many varieties all dwarf and trailing, V. gentianoides, a giant in comparison, and many others, are all free-blooming, preferring light soil, and increased by division. Besides these the annual Veronicas, which are such miserable things for summer flowering when sown in spring, are never seen to advantage unless sown in September, for their time of flowering is in the spring, and they evidently dislike the heat and dryness of summer.

Vincas are fine, especially V. herbacea, major, and minor, their foliage being as handsome as their flowers. The double variety of V. minor, which I have not seen for the last ten years, is fine, if it flowers as well as I once saw it in a clump many yards wide under the trees of a plantation.

With these must be associated the lovely spring Forget-me-not (*Myosotis montana*). It flourishes in moist soils, and in sunny situations flowers with the Snowdrop and Winter Aconite. It has flowers double the size of the Wood Forget-me-not (*M. sylvatica*), and of a brighter blue. It also continues in bloom most of the spring. Division.

I must again call attention to the lovely Hepatica angulosa, which has flowers double the size of the single blue Hepatica, of a clear and vivid sky blue. The leaves are five-lobed, and hairy. The flowers are borne on stalks from 9 to 12 inches high, and well up above the foliage.

I must conclude the list of blue flowers with Iris reticulata, which with the first return of spring sends up its dwarf stems in tufts of from 6 to 9 inches high, affording a succession of really beautiful blossoms of a deep, yet brilliant blue purple, with golden orange at the base. It will find its way into every garden, as it is a charming plant for forcing. I. pumila makes pretty groups. It grows 6 inches high, and flowers in April and May, affording a profusion of blue and yellow blooms.—G. ABBEY.

(To be continued.)

THE GROUND VINERY.

THE ground vinery is a great fact and a great success. Mr. Rivers has sent us two bunches of Black Hamburg Grapes, one taken from a Vine in the open air, and the other from one grown in a ground vinery. The former is a small insignificant bunch, with berries the size of swan-shot, green, hard, and acid; the latter, part of what appears to have been a good-sized bunch; the berries large, black as jet, thin-skinned, and deliciously flavoured. In fact they were quite equal to any that could be grown in a vinery. The site and soil of both plants were the same. The bunch of the former hung 9 inches from the ground on a Vine growing in an open border, and a few feet from the ground vinery; the latter was also 9 inches from the ground, but under the ground vinery, and with that protection such great results have been achieved.

From what we have seen in other places these ground vineries will become a necessity in every garden, and must ere long be as common as Sea-kale pots or hand-glasses. A full account of them will be found in Mr. Rivers's "Miniature Fruit Garden."

MAIDSTONE GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

A GENERAL meeting of this Society was held at the Rose and Crown Inn on the 12th ult., Mr. J. Robson in the chair.

As announced at the last meeting, Mr. Luckhurst gave an account of his experience in the cultivation of the Pear, several fine specimens of that delicious fruit being exhibited. With proper attention, some kinds of Pear trees would last two or three centuries. One of the best plans to adopt, in order to obtain a good and plentiful crop, was to graft the Pear on a quince stock, from which, with good management, some of the finest fruit might be obtained. Mr. Luckhurst then entered into a detailed account as to the best modes of training a tree, each system having its peculiar advantage, one of the principal objects in view being to make the tree look graceful to the eye. One of these modes was the horizontal system, which had a pretty effect when well trained.

Mr. Luckhurst then enumerated a number of Pears suited to the different seasons, interspersing his remarks with some well-timed and practical hints on the different descriptions. The Chairman followed Mr. Luckhurst with a few observations on the same subject, remarking that one of the most popular plans at one time was the "umbrella" system, which had its advantages, being very graceful to the eye. Another was the pyramid system, upon which Mr. Frost made a few practical remarks. A general discussion ensued, in which Messrs. Wilmore, Whyman, Davis, Luckhurst, and Frost took part, each one giving his experience in the management of the Pear tree. The subject having been fully discussed, the balance-sheet for the year was brought forward and read by Mr. Davis, from which it appeared that the Society had been formed one year, during which time its success had been far beyond the expectations of the most sanguine. During the year they had one most successful Show, and the number of members had increased very considerably. Notwithstanding the small subscription to the Society, the balance in hand at the present time was £36 13s. 2d., £30 8s. 6d. of which was placed in the savings' bank in the name of the trustees of the Society.

MR. RICHARD SMITH'S NURSERIES,

ST. JOHN'S, WORCESTER.

THESE nurseries are situated about a mile and a quarter west of the city. The principal entrance is from the Bransford road, and turning to the left a drive conducts the visitor to Mr. Smith's dwelling and counting-house, the grounds about which are flanked with greenhouses, and laid out with flower-beds on grass, rustic baskets, rockwork, water, &c. The flowers at the time of my visit were being removed, and the beds planted with dwarf plants of the Golden Arbor Vita, Silver-blotted Ivy, Golden Holly, Irish Yew, Golden-striped Irish Yew, the Heath-like Japan Cypress, which during the winter becomes of a peculiar violet red colour, and is, therefore, particularly desirable for contrast, especially with light green colours; the Black-leaved Laurustinus, Silver-striped Periwinkle, Irish Gorse, Golden-striped Periwinkle, Silver Holly with red berries, Aucuba japonica, Cerastium tomentosum, and similar plants, to give variety and contrast to what may be called the winter arrangement of the beds.

On the lawn are fine examples of Weeping Ash, Weeping Beech, the Japan Arbor Vita, a dwarf, dense, bushy, and conical-shaped kind, very desirable for lawn specimens; Wellingtonia gigantea, Quercus Fordii, Juniperus excelsa (the tall Juniper), a compact, distinct, and very ornamental pyramidal tree, rather tender, but in sheltered situations forming a beautiful specimen; Nordmann's Silver Fir, of majestic and symmetrical form, and which is most valuable in landscape gardening, its warm green contrasting well with all the shades of blue and grey; the Himalayan Spruce, the Laurel-leaved Oak, deciduous Cypress, and the Silvery-branched Virginian Cedar, which is a beautiful variety of the Red Cedar, with a peculiar whitish appearance, and very useful for contrast, for planting near water, or on rockwork, and as forming a fine cone-shaped tree. Araucaria imbricata, with its deep green foliage, rigid form, and symmetrical shape, is about 22 feet high. The lower branches from their length and weight, droop gracefully, and resemble snakes partly curled around the trunk, and stretching forth their long slender bodies in search of prey. I also noticed the Frankincense Juniper, symmetrical in form, and having delicate-looking branches, although it is so hardy that no frost will injure it; the large-coned Pine, invaluable for effect in landscape gardening; the green drooping Cedar, a very graceful variety, and as pendulous as a Weeping Willow; and the *Picea nobilis* (the noble Silver Fir), properly so named, for this is certainly one of the most majestic and magnificent trees in cultivation. Douglas writing of it says—"I spent three weeks in a forest composed of this tree, and day by day could not cease to admire it." One of the specimens here measured 3 feet 9 inches round at 3 feet from the ground, and 33 feet in height. Lambert's Pine, the gigantic Arbor Vita, the Evergreen Redwood Tree, and Cupressus Lawsoniana, were beautiful specimens. All of these are natives of California, and perfectly hardy.

On entering the grounds the first thing that arrests your attention is a carriage drive stretching two-thirds of a mile in a straight line, and altogether through the centre of the nurseries about one mile and a quarter. On each side is a broad edging of turf extending the whole length. Both sides are planted ribbon-border fashion, the first row being the Golden-striped Yew; the Nootka Sound Thujopsis, one of the most valuable introductions of late years, second; then the Irish Yew; fourth, the Deodar Cedar; then the Siberian Arbor Vitæ, well-shaped and useful for variation of colour, and the Araucaria imbricata; the whole backed by a Yew hedge. The rows at each side rise in regular gradation from the front row, 2 feet high, to the Yew hedge at the back, 10 feet high.

The next scene on the same carriage drive is a ribbon border planted at one side with a row of Golden Arbor Vitæ, then Portugal Laurel, next Irish Yew, then Thuja Wareana, backed by Irish Yew, 10 feet high. On the other side is a row of choice varieties of Green Holly, then Deodar Cedars, then Juniperus virginiana, backed by Irish Yew. The next example of a ribbon border is composed on one side of Thuja aurea, Picea nobilis, Deodar Cedars, standard Portugal Laurels, and Cedars of Lebanon; and on the other side, Golden Holly, Nordmann's Silver Fir, Irish Yew, Abies canadensis, and Thuja Wareana. The arrangement of the various ribbon lines in this noble carriage drive is well worth inspection, in order to see what pleasing effects can be produced by the judicious assortment of form and foliage.

The walk on the left communicates with the Heath-house, New Holland-house, Pelargonium-house, stoves, Fig-houses, propagating-houses, &c., all heated by hot water, and containing a choice collection of young healthy stock. On the right is a house for growing young Vines, 117 feet long, by 17½ feet wide, also orchard-houses, the first nearly 200 feet by 27 feet; another 115 feet, by 25 feet; one 45 feet by 25 feet; and another for growing Figs, 50 feet by 33 feet. There are many thousands of orchard-house trees in fine bearing condition. Altogether there are sixteen large houses for various purposes, and one thousand glass pits, and about three acres of raised brick-beds on which lights can be placed for newly-transplanted stock.

Continuing along the drive which connects the various nurseries together, passing large beds of Araucarias, *Abies excelsa inverta* (a new weeping variety), *Picea nobilis*, *P. amabilis*, *P. Nordmanniana*, *P. Pinsapo*, *Wellingtonia gigantea*, *Thujopsis borealis*, *T. dolabrata*, *Podocarpus* of sorts, and masses of many other valuable evergreen Conifers, of which tribe Mr. Smith's stock is allowed to be the finest in the kingdom, we come to a nursery where quarter after quarter, to the extent of thirty acres, is occupied with evergreen trees and shrubs of all hues, sorts, shapes, and sizes, in most luxuriant health. These are cultivated with the greatest care. Mr. Smith never allows any stock to exceed three years without removal, and every plant is formed from its earliest infancy to make a handsome specimen, and thus by timely care the most perfect form that can be desired is obtained without formality and without stiffness.

Thence we pass to the Rose ground of eight acres, and containing one hundred thousand Roses. How, "D., Deal," would revel amidst the beauties he would there behold

"In all their crimson glory spread,
While, drooping fresh the dewy head,
They scent the early morning."

In order to give the public some idea of the stock, I will only observe that standard, half-standard, dwarf, pyramid, bush, orchard, and wall fruit trees, occupy more than forty acres.

We now come to the Gothic lodge at the entrance from the Malvern road, and cross to the nursery opposite, where fruit, forest, and flowering trees each take their place in the most convenient and suitable arrangement. Each class of stock by itself, and the whole arranged for convenience and general effect, is the primary aim in every department.

There are hundreds of standard Portugal Laurels 6 feet high, very handsome for terraces, they make good substitutes for standard Orange trees. The Colchian Laurel, of which there is a large quantity, is different from the common Laurel in leaf, it is more upright and hardy.

The large and commodious packing-shed, with other

offices, is situated in a central part of the ground, it has a large crane attached for loading vans, &c.

To account for the luxuriant state of the young stock which is propagated by thousands, and then transplanted into the raised brick-beds, and the fine stock in the home nurseries, it is only necessary to state that the whole is watered by underground iron pipes and flexible hose, a means to an end which is well worthy of adoption in many places.

To sum up some of the principal features of this establishment, it is worthy of remark, that there are never less than seventy men employed, and the number varies from that to often one hundred and thirty. The space occupied in the cultivation of young stock is thirty acres, and about one million of Conifers and ornamental trees, besides other stock, are annually produced. The glass houses, pits, &c., comprise an area of 64,000 square feet. There are twenty-one miles of walks, though no more exist than are absolutely necessary for convenience in seeing and cultivating the stock advantageously. There are 400,000 stakes used annually, and eighty tons of garden-pots. Besides the nursery, Mr. Smith has a very large seed business connected with his establishment.

The whole was in first-rate order, not a weed to be seen in any department, which reflects great credit on the very intelligent foreman, to whom I am indebted for many of the above particulars.—WILLIAM KEANE.

NEW ZEALAND SPINACH.

ALLOW me to call attention to this vegetable (*Tetragonia expansa*), which I think is not so well known as it deserves. It is most useful, quite equal in flavour to the common Spinach, and more ornamental, having much the appearance of the Ice Plant, which it almost equals for garnishing. It comes in at a season when the common kind is of little use from its so soon running to seed. During the present dry season it has been most valuable, sixteen or seventeen plants having furnished a nice gathering once and twice a-week for the last three or four months; and they will continue to do so till killed by frost.

I find that it does well planted between rows of early Peas, the shade being grateful to it in its early stage of growth; and it comes into use about the time the Peas have to be cleared off. The treading about it in gathering the Peas appears to suit it.

For the information of persons not acquainted with it, I may as well mention that it requires the same treatment as tender annuals—viz., sowing in heat during March or April, pricking off, and planting out towards the end of May, allowing a square yard for each plant. By gathering the young tops for use, great numbers of side shoots are produced.—J. T. CREEDE, *Gardener to T. Swanwick, Esq., Whittington, Chesterfield.*

A CROP SAVED BY THE BIRDS.

I FEEL it my duty to report an instance which I think will go far towards establishing the fact that birds are of great service to the gardener. About five weeks ago my crops of Brussels Sprouts, Broccolis, and Savoys, amounting to some hundreds of plants, were attacked by a multitude of caterpillars; and so severe was this attack that I anticipated the destruction of my crops, and many who saw it pronounced it to be in excess of anything they had ever seen before. I communicated with the Editors of this Journal concerning it, and before their reply came to hand the blackbird, thrush, tomtit, and robin, came to the scene of destruction, and in three days there was not a dozen caterpillars to be seen, all being carried away and eaten by these birds. I can, therefore, report a crop saved by the birds. I may mention that this is not the only instance which I have noticed of the good effected by these birds.—THOMAS RECORD, *Belmont, Hendon.*

DAHLIA GLABRATA.—I have now (Nov. 1), in my garden in full bloom and beauty an elegant little flower, to which I have attached the sobriquet of the "Lady Flower," from the fact of the attention of all ladies being immediately

riveted upon it, from its extreme simplicity and elegance. Its name is the Dahlia glabrata, and the seed of it may be procured from Mr. W. Thompson, of Ipswich. It is a small single Dahlia from $1\frac{1}{2}$ to 2 inches in diameter, of colours varying from deep purple to milky white. It is charming in a bouquet.—T. S.

GARDENERS EMIGRATING TO NEW ZEALAND.

NEW ZEALAND consists of three islands, two large and one small; the larger are separated by Cook's Strait, a channel about 50 miles broad—distance about 1200 miles from Australia. New Zealand contains nearly 75,000,000 acres, or is about as large as Great Britain and Ireland. It contains nearly 50,000 natives, and from 90 to 100,000 Europeans; but as ships are weekly arriving with emigrants this population cannot be exactly stated. The climate is considered as healthy, or rather more so, than that of England, January being the hottest, and July the coldest month. There is more wind and rain than in England, but fewer wet days, as the rains are heavier than here. The summer is a little warmer, and the winter much warmer than in England; mean temperature of the New Zealand summer 65° , that of the winter 50° ; but in so large a place it varies, the north island being a few degrees warmer than the south. Winter is not much colder than a cold wet English March. Our common bedding plants, as Geraniums, Verbenas, &c., will live out all the winter in the north island, and in the south will survive with a little protection. There are no wild animals hurtful to man. Minerals are rather plentiful, but not much worked as yet, as wood is the chief fuel, and it is dear. Greater part of it is found in the north island. Most trees, shrubs, fruits, flowers, and vegetables, that will succeed in England will do so in New Zealand; and others that require a warmer winter than ours may also be grown. Gooseberries and Currants, particularly Black Currants, do remarkably well. I find Quick Thorns are used, mixed with Furze, for hedges. Seeds of all kinds that are good should be taken, as good seeds are always valuable here, and doubly so there. Food is dear, bread 1s. 4d. per four-pound loaf, meat 8d. to 10d. per pound, and house rent very dear.

A handy man would perhaps receive 8s. per day—at least my friend does, but he is not afraid to rough it. Such a man is almost sure to get on if sober and industrious, although it is common to hear people say "I wish I were in England again." People must make up their minds to rough it for a year or two, and the wife must have good heart, and deny herself many little things for a time, such as comfort in furniture, &c., unless the married couple have a good sum of money to furnish with. My friend says, if the wife has good heart nearly all the battle is won. My friend, after being there some time, bought a quarter of an acre of land for £50, paid £17 down, and £33 by instalments, and paid interest at the rate of £6 10s. per cent. He afterwards borrowed £100 at £12 per cent, and built a cottage costing £150; land, building, fencing the ground, and the titles, cost £221. He paid in a little over four years £130, or about £30 per annum, but has two children that are helping him; one, a girl, sixteen years old, is getting £20 per year with board and lodgings. His advice is, to any one going out, take all you can, tools, furniture, clothing, &c., as they are mostly double the price they are in England. It is a very serious journey, and he would not advise any one to go without much thought about it, and a determination to be sober and industrious, and rough it for a year or two. A character from the last master, as well as one from the clergyman, are very valuable. Schools and places of worship near towns are good, as well as pretty plentiful. He advises me not to leave my place to go out, but should I have left, and have a difficulty in getting another situation, to venture out.—W. C.

PANSY.—It is no doubt true, that the word Pansy is derived from the French *penser*, to think; although Ben Johnson spells it *pauusé*, Spenser (Shep. Cal., April, l. 142), *paunce*; and Milton, in Comus, speaks of *pancies*. I agree, however, with Grime in thinking Dr. Richardson's account of the origin of the name unsatisfactory. I should be inclined to

regard Pansy as one of a long list of names bestowed by the quaint fancy of our ancestors, who, by fixing, often perhaps arbitrarily, on certain flowers to express certain ideas, constructed a language of flowers. The grotesque appearance of the full-blown Pansy may, perhaps, have led to the imposition of the name, but only because it may have led to the selection of the flower as an emblem of "thought." At any rate Ophelia (Shakspeare's Hamlet, Act IV. Sc. 5), uses the Pansy as an emblem:—"There's Rosemary, that's for remembrance. Pray you, love, remember; and there is Pansies, that's for thoughts." Quesnay, the physician of Louis XV., and leader of the Economists, was called by the monarch his "thinker," and granted for armorial bearings three flowers of the *pensee*. The following is a list of some of the names by which the Pansy goes with rustics and old writers:—Heart's-ease—Herb Trinity—Three-faces-under-a-hood—Kit-run-about—Cuddle-me-to-you—Love-in-vain—Kiss-behind-the-garden-gate—Jump-up-and-kiss-me-my-love—Love-in-idleness. Under this last name Shakspeare speaks of it in the famous passage, Midsummer Night's Dream, Act II. Sc. 2:—

" Yet marked I where the bolt of Cupid fell;
It fell upon a little western flower,
Before milk-white, now purple with love's wounds,
And maidens call it 'Love-in-idleness.'"

In the description of the effects of the flower that follows, there is evidently an allusion to the emblematical significance of the Pansy:—

" The juice of it on sleeping eyelids laid,
Will make a man or woman madly dote
Upon the next live creature that it sees."

And again below:—

" And with the juice of this I'll streak her eyes,
And make her full of hateful fantasies."

German rustics, I am told, call the Pansy *stiefmutter*, step-mother.—*FABIUS OXONIENSIS* in *Notes and Queries*.

THE IRISH POTATO CROP OF 1864.

THE Irish Potato crop of 1864 is, perhaps, the finest that has been turned out of the ground for a quarter of a century. In some parts of the country where old lea lands were broken up and planted last spring the produce has reached a point hardly ever before attained. One instance we have heard of is that of a Down farmer who planted a small field with the variety called "Skerrys," and the produce raised amounted to 1000 bushels, being at the rate of 600 bushels to an Irish acre. Other cases have been recorded this season where a still larger turn-out has been taken up. In the palmiest days of Potato-growing, and ere the blight was heard of in Ireland, the average of 250 bushels of Potatoes, fit for market, to the statute acre, was thought a fair crop; for even then there were always found considerable quantities of inferior and unsound tubers which were thrown aside to be used in cattle feeding. The care taken by growers for some years past, as well in the selection as in the change of soil for their Potato lands, has had the best effect on the crop; and, after long perseverance in the right path, the Irish farmer has reached a degree of success unequalled in the history of agriculture. It will be recollected by those who paid any attention to the subject that for a great many years before the setting in of the Potato disease it was not unusual for farmers to continue planting as seed the same variety of Potatoes, and this course was continued until the root had reached the highest degree of excellence as an article of food. In proportion, however, as some varieties of the article excelled in quality for table use, their value as seed declined; and, when planted season after season, the natural vitality gave way, until at length direct disease came on the crop and general destruction followed, bringing want and misery to the doors of thousands of the peasantry.

The old habit of living half the year on the produce of his Potato plot has ceased to be the rule of the cottager in every part of Ireland. He no longer depends on the turn-out of a precarious crop for his subsistence. One of the results of the famine season, with all its dread realities, has been to familiarise the masses of the people in this country with a class of food much superior to that with which their fathers were accustomed to be content. If, therefore, the Potato

lands were again to be visited with the blight which made such havoc among them, the effect would now be much less serious than it was eighteen years ago. As it is, the blessing of abundance will prove most advantageous this year, not only to the people as food, but to the farmers as additions to their material for the stall feeding of cattle.—(Banner of Ulster.)

JAPANESE PLANTS AND CULTURE.

Kanagawa, June 21st, 1864.

So much has been written by others about the natural products of Japan, that little remains to be said, having reference entirely to the limited range foreigners are permitted access to. Mr. Fortune's book being especially devoted to such subjects, is, of course, the most complete. Hodgson, in an appendix to his book, has a catalogue of native plants which I have not had an opportunity of examining. Mr. Veitch contributes to Sir R. Alcock's work valuable notes on the plants of Japan and its agriculture. He has, however, fallen into some few errors, which it may be as well to correct.

Among the plants enumerated as growing wild are Nerium oleander, Vinca rosea, Balsamina hortensis, Celosia cristata, and others, which are undoubtedly all introduced; certainly they are not found growing in a wild state in this neighbourhood. In another place he speaks of wild Strawberries, probably referring to a Potentilla bearing a profusion of tasteless fruit, very much resembling a small Strawberry.

In my last I gave the names of some exotic plants cultivated by the native gardeners. To these are to be added the Chinese Hibiscus, Pomegranate, Echinocactus Fyresii, and Epiphyllum, Justicia carnea major, a Quisqualis, Myrtus tomentosa, Tecoma jasminoides, Sago Palm, Oxalis Bowiei, Ardisia crenulata, and another species of which there are a dozen varieties, with variegated and curled foliage, with red and white fruit. They are entirely unique, and, indeed, I have seen no more valuable acquisitions in variegated plants, or any possessing greater interest than these as most beautiful additions to the already numerous list of hothouse plants of that character. These exotics could only have been received from the Dutch and Portuguese in early times; and considering the limited intercourse allowed with foreigners, they are evidence that the florists of Japan are not without enterprise in their business, and ready to avail themselves of every opportunity of adding rare and beautiful plants to their collections.

I was surprised one day, on showing a prominent Japanese merchant a representation in stone of some foreign Pears, to see that he recognised the fruit, and to hear from him that a few trees were growing in the garden of a doctor at Miaco. I felt inclined to doubt his statement, thinking he was confounding them with the native varieties. He had, however, another name for them, and insisted on the correctness of his knowledge; also stating that the M.D. used the fruit for a medicine—an excellent way of disposing of his crop at remunerative prices. If they are foreign Pears, it is singular they have not been distributed.

One cannot help feeling a regret, apart from commercial interests, at the mutual consents given by other governments to the closing, for the present, of Kioto, the port of Osaca, near Miaco. That city is the Paris of Japan, wherein is collected all that is rare and beautiful. As many as are the floral treasures obtained here, I have not the slightest doubt many more could be added to the number, if we were allowed to explore the gardens there.

Not the least beautiful of Japanese plants is the Iris, of which many varieties are cultivated, from the purest white to the darkest blue, with all manner of intermediate shades and pencilings. I shall have a collection to send home the coming autumn; and if they survive and bloom, when you see them you will agree with me in saying their merits deserve that they should be classed as a florist's flower.

An addition to the conservatory will be Magnolia parviflora, a species after the style of *M. pumila*, only of a more robust growth, with pure white flowers of a delicious fragrance.

The Maple, in all its variety of variegated and dissected leaves, will prove to be among our finest acquisitions of ornamental hardy trees. The golden-leaved Pines are also to be

included in the list of decided novelties. I fear the difficulty of transporting them safely so great a distance will prevent their introduction for some time, or until some one can give personal attention to them on the voyage.

I flattered myself this spring that I had obtained from Yedo a collection of twenty varieties of Tree Paeonies, having given a dealer here directions to obtain that number of the most distinct and best from out of forty or fifty he said were cultivated. I believe he performed his part to the best of his knowledge; but, unfortunately, he had to purchase them in bud, and when they bloomed I found only six or eight sorts. These, however, although not what I expected, will prove valuable as a source from which new sorts may be obtained by hybridisation.

A fine addition to the greenhouse is an Orchid very similar to, if not a species of, *Bletia*, in growth like the old *B. Tanckevilliae* [*Phaius grandifolius*.—Ed.], only more beautiful than that old favourite.

In passing the other day a small garden in an obscure situation, I saw growing a row of young plants of Indian Corn, with leaves distinctly striped with white. Of course I made a note of it, to procure seed at the proper season. Who knows but what, after a while, the vegetable gardener may invite you to look at his gold-blotted Cabbage, his tri-coloured Lettuce, silver-margined Squashes, or striped Cucumbers?

The past winter has been exceedingly dry, and somewhat colder than usual. The spring too, has been more backward, but seasonable rains came on in time for the Wheat and Barley crops. The harvesting of the last is nearly over, and that of the Wheat will soon commence. Farmers are now also busy transplanting Rice from the seed-beds to the paddy fields. This work, although not laborious, would, to those who perform it be exceedingly unpleasant, as those who perform it have to wade all day long knee deep in water. It is chiefly done by women and boys, the men performing the severer labour of preparing the fields for the reception of the plant. Mr. Veitch says the transplanting is done in April. He probably refers to sowing the seed in nursery-beds.

Immediately after the grain crops are harvested, no time is lost in sowing Cotton, Sesamum, Buckwheat, and Sweet Potatoes. Their system of liquid manuring enables them to plant at once, without any further preparation of the soil than simply opening the drills for the reception of the seed. They practise sowing seed very thickly—I should think twice as much as is necessary, the surplus being just so much grain lost. Millet and Maize are both transplanted, but neither to the extent to entitle them to the name of a field crop. Potatoes are in blossom, and are now looking fine. The late rains will aid them very much in producing a large crop, which will be wanted to help to feed the small army of foreign soldiers now gathering here for the purpose of reconciling the Japanese government to the inevitable change that must take place in their policy towards other nations, or, in other words, bayonet reconciliation. Not the least consideration with myself is, that in the end freer access will be permitted to other portions of the country.—T. Hogg.—(*American Gardeners' Monthly*.)

ENVILLE HALL.

(Continued from page 356.)

PLEASURE GROUNDS.

As we return from the kitchen garden and cross the roadway already referred to, we might enter the flower garden and pleasure grounds of 70 acres by the post-office private entrance (4), close to Mr. Craw's residence; and having passed the three lakes termed the conservatory pools (20), we would obtain, as far as the inequality of the ground will permit, a bird's-eye view of the whole up to the extreme southwest point, where the pagoda is placed some 200 feet above the level of these pools. With great undulations (one of the chief charms of these gardens), the grounds as a whole rise sometimes gradually and at other times abruptly from this level to the boundary woods and sheep-walks beyond. A line from the mansion on the south to beyond these pools on the north, and not distant from the private road, might be considered the base of an unequal-sided triangle, which

formed the greater part of the dressed grounds ; the pagoda standing in the acute angle opposite the base, and the sea-horse pool and Jordan's pool, with their splendid fountains, being on the south side of the triangle. Such, we think, would be the best entrance for a stranger with little time to spare, and who wished to carry away with him the preponderating ideas of the vast and the magnificent as well as the beautiful.

But to obtain anything like a clear idea of the diversified interest of Enville, we would advise the stranger to do just what we will attempt to do with our readers—take them with us, and enter by the same bronzed gates that admit the general public (*la*), without going so far as the entrance (*1*), that leads to the mansion (*2*), as gardening rather than architecture is our theme.

Opposite the entrance is a rabbit-yard and aviary (*3*), both in excellent condition, and furnishing endless amusement and instruction to those who, like Lady Stamford, are partial to the study of such departments of natural history. The interest of these places is greatly increased by the rabbits not only having every convenience, but full opportunity for holeing and burrowing, and by many of the birds showing off the brightness of their plumage to advantage from being allowed ample space and protection among the sombre Yews and other evergreens that separate these yards from her ladyship's garden (*6*), and her dove-house (*16*), which is equally sheltered and interesting.

But as flowers are our object at present, we enter a walk that runs northward again, separated by a wall from the roadway, called the Rose walk, and beside it is a straight ribbon-border (*5*). The wall is covered with Wistarias, Jasmines, Honeysuckles, &c. Then climbing Roses are festooned, and half-standard Roses in a line in front, the ribboning being then Brilliant Geranium, Aurea floribunda Calceolaria, Lobelia speciosa, and Cerastium next the grass verge. This border was very nice as the first dish of the banquet.

A turn to the left from the middle of that ribbon walk brings us to Lady Stamford's flower garden (*6*), behind the aviary. This, though most simply arranged, is interesting as almost the only attempt like combination or massing of groups to be found in these gardens. The garden is centered by a large elevated basin fountain of the shell pattern, surrounded by eight circular beds of good size. Four of these beds were filled with blue Lobelia, with a broad edging of a pretty pink Verbena pegged down; and the other four, placed alternately with these, were filled with Countess of Warwick and Christine Geraniums, and three rows of Golden Chain next the grass. The Golden Chain does admirably in these gardens. A horseshoe or semicircular ribbon-border, next the Yews and evergreens, surrounds the half of this garden, and was thus planted, beginning at the grass : Lobelia speciosa, Aurea floribunda Calceolaria, Emperor of the French Geranium, Hendersonii Geranium, and standard Roses in front of the fine bank of evergreens.

This little garden is open to the walks on the north and west sides, with the exception of some small circular beds (represented thus in the plan), about 3½ feet in diameter or less, at something like regular distances near the sides of the walks, each centred with a Rose or Humea, and variously filled with bedding plants. There are several hundreds of these small beds over the ground, and all we saw were filled with great taste, though in some cases it seemed to us that their absence would have been more gratifying than their presence, as interfering with breadth of view and confusing rather than giving repose to the eye.

On the open side of this garden is a fine specimen of the Venetian Sumach (*Rhus cotinus*), which, though perhaps not more than 10 feet in height, is 89 feet in circumference of head, and must have been a splendid sight when covered with its feathery spikes of bloom. Though originally one plant, some of its branches had bent themselves to the ground and thrown up stems, but this is not seen without examination.

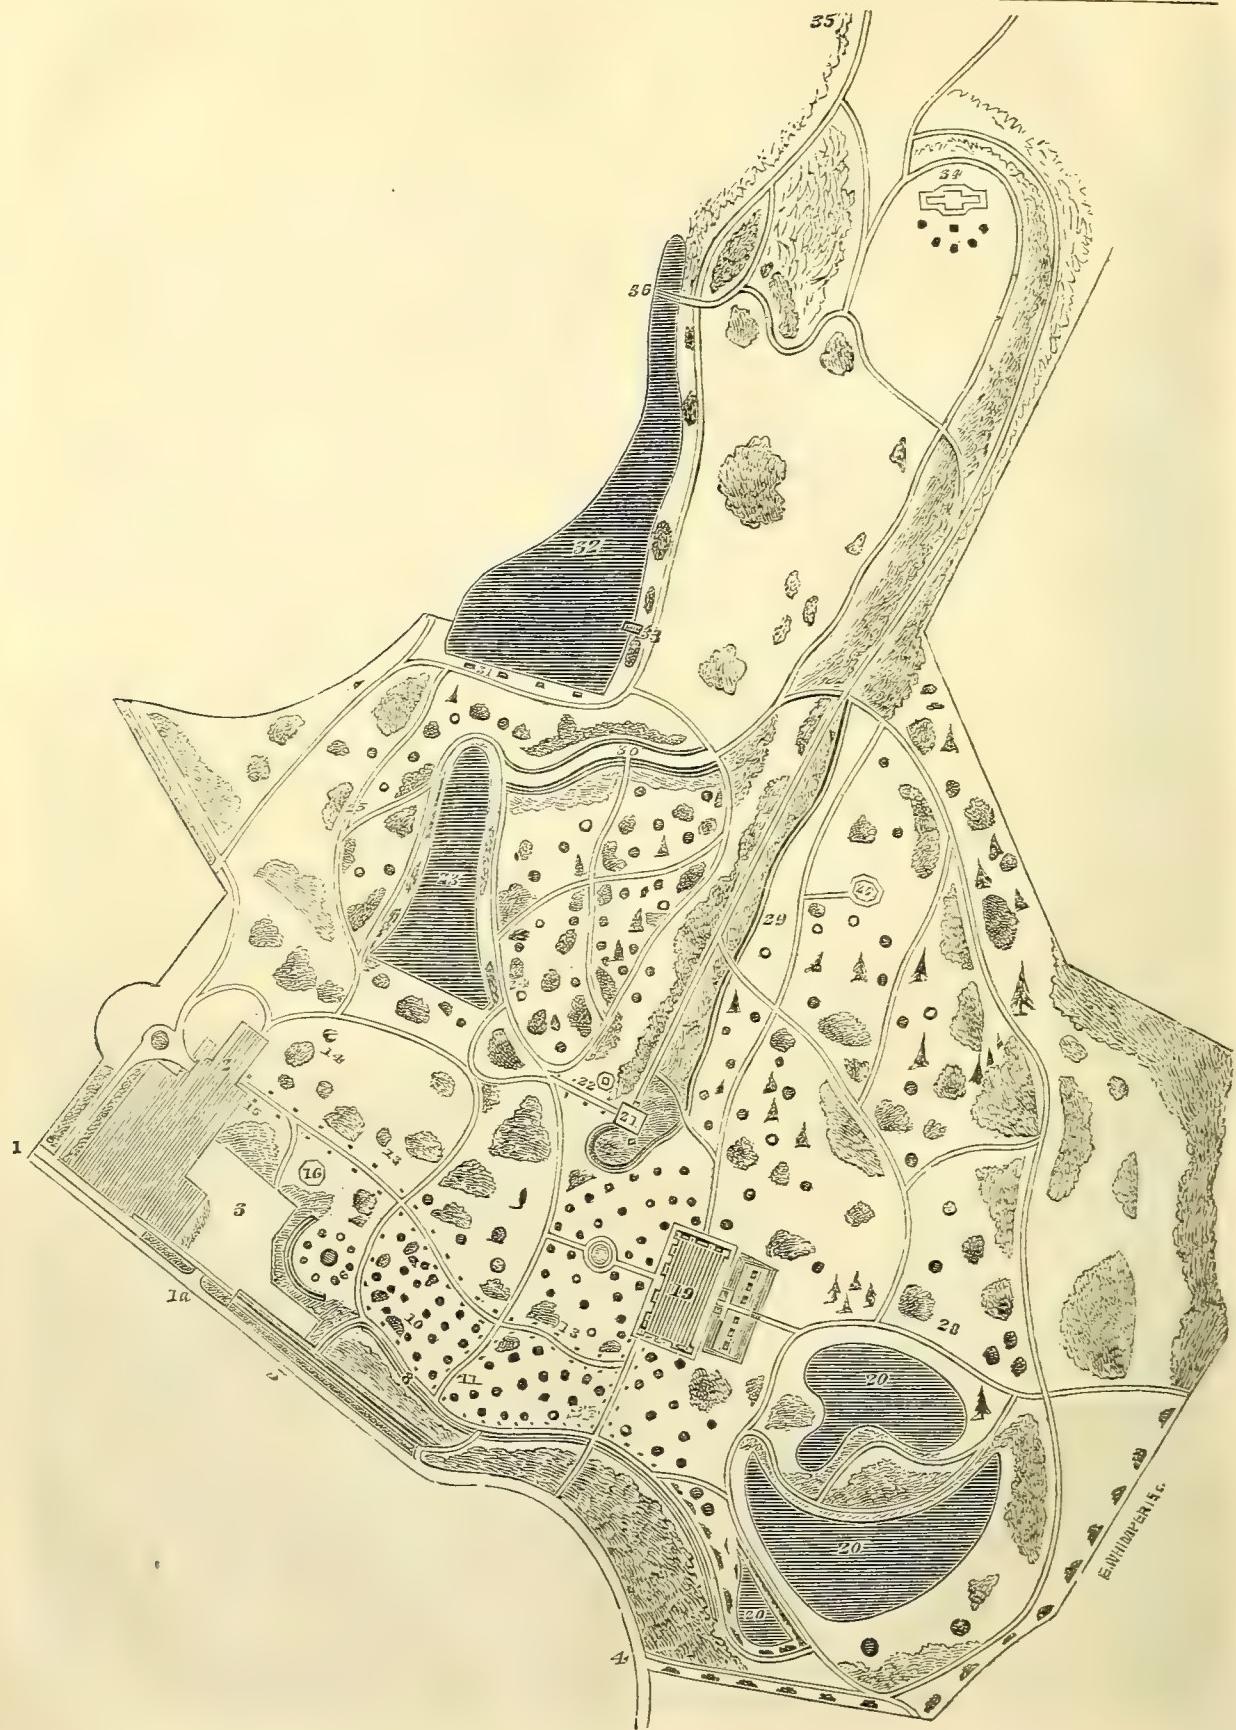

From this garden a walk leads to the north front of the mansion, passing the dove-house (*16*), itself backed by a noble mass of Portugal Laurel, and fronted nearer the mansion with a splendid plant of the same (*15*), that has layered itself a little like the Sumach and is fully 200 feet in circumference of head. This is paired on the other side of the walk by a fine Rhododendron ponticum (*14*), the head

of which is 185 feet in circumference as it sweeps the ground. That is the measurement given to us as correct by one of Mr. Craw's assistants. Our own measurement from stepping round it made it 1 foot more. Just opposite the dove-house is a fine Purple Beech, with its branches sweeping the lawn, and there are several other nice trees and masses of evergreens besides. Now, though flowers are attractive, place them where you will, we must own that we would rather have seen none of these small beds by the sides of this walk from the mansion, and for these reasons: Their smallness detracts from the dignity of the mansion; they tend to fritter away by their very regularity, instead of enhance, the magnificence of the fine specimens of trees and gorgeous masses of shrubs, more picturesque than formal in their outline, and by the eye being accustomed to flowers, though in small masses, the visitors from the house would be less astonished and delighted by the large circular masses of bloom in Lady Stamford's garden, and in the five or six assemblages of these large circles that stretch in different departments, each with its own distinctive name, from Lady Stamford's garden to the conservatory pools, and westward beyond the conservatory. If any possible improvement as to floral display is to be effected at Enville, it will be done more by aiming at concentration than diffusion—more by giving increased relief and repose, and therefore augmented variety, than by the bewildering repetition that is apt to terminate in confused sameness. Great minds there may be to whom nothing is impossible, but to the most of us there is a difficulty in comprehending and analysing the attractions of different objects when presented to our view at one and the same time.

Returning to the north-east side of Lady Stamford's garden, we enter on a winding walk that leads to the conservatory pools (*20*), passing on the left hand three of these departments or gardens for flowers, grouped with large circles in the middle and small ones round the outside. In the first department, containing a fine specimen of *Pinus macrocarpa* (*10*), we counted twenty large circles, and about the same number of smaller ones. We cannot even attempt to describe the planting of these, or the 160 beds in all, ranging from 18 to 23 feet in diameter, but we will ere long give the planting of a few as an example. The second department, among other evergreens has a fine specimen of *Thuja aurea* (*11*), and a large *Wistaria sinensis* now trained round hoops, and which generally blooms well. The plant was formerly trained against the walls of an orangery which has long been removed.

On the right-hand side is one of the finest features of Enville in a floral point of view, in the shape of the post-office ribbon-border, so called because extending from Lady Stamford's garden to that private entrance, running nearly parallel with part of the straight ribbon-border already referred to (*5*), and with the private road, but so thoroughly blocked out from both that you might well imagine there were no such things near you. Beginning at the grass verge this border was planted as follows: Two rows of Golden Chain Geranium; a broad band of Lobelia speciosa from seed; a fine row of Little David Geranium, dwarfed and more free-flowering than Tom Thumb; a fine thick row of Flower of the Day Geranium with the flowers nipped off; a row of Perilla, with standard Roses at regular intervals; and the back row Hollyhocks, chiefly grown with a single stem, and which showed to great advantage from the dark mass of evergreens behind them, relieved, however, by the varied hue of the finer-foliaged Hollies. Golden Chain was thoroughly at home in the front belt, and to make this three thousand good plants were required. This ribbon was a gem.

The pools to which we have now come are different, but communicating with each other. All are well supplied with waterfowl, and their banks are well fringed with plants, chiefly Rhododendrons, Willows, Alder, &c., except the south and west banks of the upper pool, which thus bring the water in view from the conservatory. The east side of that pool, besides the evergreens, was also fringed with some herbaceous plants, as Variegated Balm and Variegated Alyssum; but any thoughts of their appositeness for the situation were dispelled by the proud demeanour of the swans, who followed us all round the upper pool, no doubt disputing our right to visit their domains. Between the

middle pool and the east end of the conservatory is a fine mass of evergreens, fronted with Rhododendrons. On the south side of the upper pool close to the water is a fine mass of Oaks; and on the west side is a fine old gnarled Oak, with the top branches beginning to decay, telling of the hundreds of years it has braved the tempest as well as the breeze (28).

From the vicinity of this Oak (28), a good view is obtained of the north side of the conservatory, and the pinnacles of the museum and smoke-tower; and direct west on to the owl and eagle-house, and thence to the pagoda is comparatively open lawn, with dense groups of evergreens, and Pines, &c., thinly scattered and enlivened by but few of the large circle flower-beds which so bewildered us near the fine ribbon-border. As to the eagle-house (27), we may here say, that it is a fine, strong, rustic structure surrounded by stout wire fencing. There are fine specimens of both kinds

of birds; but what rather surprised us was the fact, that though there are large holes made in the artificial rock for the denizens to retire to when they think proper, especially in severe weather, they hardly ever enter them; and even the owls prefer building their nests and hatching their young on the ground in a sheltered place between jutting stones, instead of going into the deep recesses which we would have thought they would use.

The conservatory (19), is a very elegant building combining great artistic and architectural taste with much fitness for the object contemplated. It was designed and erected by the late firm of Messrs. Gray & Ormson. It is in length 160 feet, and in breadth 79 feet. It stands upon a raised platform some 20 feet above the level of the upper pool, and has a broad gravel terrace all round it, graced with fine pyramidal plants of Sweet Bay in tubs. These fine Bays are placed under protection in winter. The stoke-

CONSERVATORY AT ENVILLE.

holes are reached from an opening, close to the steps, in the sloping bank on the north side of the terrace. Three boilers are used, and 5000 feet of four-inch piping.

On the lawn at the base of this slope are placed six raised beds or baskets of an hexagonal or octagonal shape, their sides covered with bark, and these baskets were all planted in the mixed style; all attempts at artistic arrangement being thoroughly concealed. They afforded a relief after looking at the hundreds of flower-beds, so neat and trim that not a twig or a blossom seemed as if it could get out of place. We were reminded of what we have sometimes noticed in nosegay making—one person will take a long time to produce a desired effect, and after all the composition will be as stiff as a poker in its symmetry; whilst a young lady in a few minutes will go to her own border, pull a sprig here and another there, place them in position as she goes along without making great pretensions to aiming at taste, and yet eight out of ten people would prefer the

nosegay thus huddled together just because there was more of the natural than the artistic about it.

The inside of the conservatory is not yet finished, as it is desirable to allow the ground full time for sinking and becoming consolidated before putting down beautiful pathways. On this account little except a few creepers are permanently planted out. There is to be a wide pathway or road down the centre, and narrower ones along the sides, and by the sides of these paths the pipes for heating are placed in chambers, with open iron-grating work over them. The main supports of the building are of iron, and the main columns are hollow to act as drain-pipes from the roof. All the rest for the reception of the glass except the domes is formed of wood. The ventilation is ample, and the tops of the domes are easily opened and shut by a wire rope concealed among the climbers round the pillars. About the middle of one end were two fine plants in tubs of *Araucaria excelsa*, which will soon be through the roof if not provided

for elsewhere, and to balance these on the other side were two fine plants of *Yucca*, or *Dracena*, with good clear stems and large heads of green leaves. *Camellias*, *Azaleas*, *Oranges*, *Fuchsias*, &c., made up the most of the present furnishing, and the prominent creepers and climbers dangling in profusion from the roof were *Tecomas*, *Acacias*, *Passifloras*, and *Tacsonia mollissima*.

We forgot to mention, that the smoke from the furnaces of this conservatory is conducted underground to an elegant tower at the north-east corner of the museum (21), and at a short distance from this museum is Lady Stamford's dove-house (22), where an interesting collection is kept.

From the middle of the terrace on the south front of the conservatory a walk, with flower-beds on each side, leads up to an open lawn on which are some wonderful Lime trees, of which more anon. This walk if it had gone straight on would have landed at a fine Rhododendron close to the mansion. At the centre of this walk there is a beautiful basin and fountain with fine specimens of pyramidal Sweet Bays set round it in tubs on the gravel. The basin is deep, but to prevent waterfowl from getting in and possibly not getting out, strong wire-netting is placed across some 15 inches or so below the surface of the water. We have thought that the large beds, some 20 feet in diameter, placed on each side of this walk on the south front of the conservatory might help to give an idea of the system of planting. We will just premise then that the opposite beds were planted alike to balance each other, as well as to contrast with their neighbours, and that in the first row next the walk there were four beds; in the second and third rows three beds; and these were mostly placed so that the beds in one row angled the beds in the other row next it.

In the first row then, beginning at the conservatory, the opposite sides of the walk being the same, the first bed was Little David Geranium, edged with Variegated Alyssum; the second bed Lobelia speciosa, edged with Golden Chain Geranium; the third bed the same, being on the opposite side of the fountain; and the fourth bed was a repetition of the first. In the second row, the first bed was Hendersonii nana Geranium, edged with Pink Pearl Geranium; second bed, Rosy Queen Geranium, edged with Ageratum kept low; third bed, Hendersonii Geranium, edged with Pink Minimum Nosegay. In the third row, the first bed was Purple King Verbena, edged with Lord Stamford Verbena, a white-leaved variegated with pink flowers and much valued; second bed, Emperor of the French Geranium plunged in pots, edged with Purple King; third bed, Amplexicaulis Calceolaria, edged with Amaranthus melantholicus, the latter doing well; and so on with the other rows. These beds from their very massiveness looked very well. All these beds and also the other circles were raised in the centre so as to make half, and some fully more than half a ball, and all were densely filled.

Among the many fine beds, it may not be amiss here to mention a few that struck us as being particularly fine; and here we must, perhaps, mention first the circle 23 feet in diameter, near the lower conservatory pool, planted with Trentham Rose Geranium, and densely edged with Centaurea candidissima, and a bed of the same size filled with a fine dark Petunia, named Lord Stamford. Then the following beds—Amplexicaulis Calceolaria and Ageratum; again with Amaranthus, and again with a strong blue purple Verbena; Gazanias, very fine, with blue Lobelia; Brilliant Geranium with Purple King Verbena; Cloth of Gold Geranium and Purple King Verbena; Purple King and Lord Stamford Geranium; Pearl Geranium, a dwarf pinkish Nosegay, with Madame Vaucher; Alma Geranium with Trifolium repens nigrum, a pretty bed; Lord Stamford Geranium with the above Trifolium; Lobelia speciosa, strong plants from seed, edged with Gazania splendens; Geranium Rosy Queen with Ageratum; Trentham Rose Geranium and Cineraria maritima; Mrs. Pollock Geranium and Lobelia speciosa; Purple King Verbena, and Lord Stamford Geranium, &c. Nothing surprised us more than the extreme brilliancy of the Amplexicaulis Calceolaria, which made it a striking feature all over the grounds. It used to be equally fine with us, but owing to the drought and no water to help it, we had but few flowers after the middle of August.

On second thoughts we think it better to defer some concluding remarks—a few words on the style of arranging these huge beds.

From the south of the conservatory a fine peep is obtained of the top of the museum, and the elegant smoke tower, surrounded with Ivy, and banked up with huge banks of evergreens; and between the museum and the fine Lime tree, the eye passes far beyond the dressed grounds to the arched gates that lead to the drive in the woods, that takes onward to the more elevated sheep-walks. In the front of the above bank of evergreens at the museum, extending a long way westward, is a narrow ribbon border of three rows (29), *Manglesii Geranium* next the grass, *Brilliant* behind, and then *Amplexicaulis Calceolaria* next to the bank of green and telling very much by its bright yellow for a great distance.

Of the museum itself, though we took a few notes, we must say nothing of its birds, and fishes, and animals, and shells, and fossils, and ores, and minerals, and kinds of rocks, but from its pinnacled turrets, and pretty oriel windows, and its position on a knoll, and its background of trees and evergreens, it forms a fine feature to the grounds from many distinct points of view.

R. FISH.

(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

KEEP the heaps of compost well turned over, as the time is approaching when every advantage must be taken of frosty mornings to wheel it over the land. As a general rule, ground that is very deeply trenched should be manured after the trenching, and the manure forked in, except in the case of its being intended to be cropp'd with tap-rooted plants, which will require the manure to be trenched-in deeply, and not incorporated with the surface soil. Trenching all vacant ground must be vigorously followed up, taking care to trench-in all green and decaying refuse, which is better than throwing such materials in a heap to decay, which entails a positive loss of fertilising matter. *Broccoli*, it is now high time to perform the operation termed "laying" with the stock of spring *Broccolis*. A tender vegetable will endure severe weather better when deprived of a portion of its succulence than when overtaken by frost when in a luxuriant state. *Cauliflowers*, those already headed to be carefully taken up and stacked in a dry pit, or under the protection of a wall, where a thatched shutter may be employed in unfavourable weather to ward off the wet. *Endive*, as many as possible of these plants and of Lettuces should be transplanted into frames, where they may be at least protected from rain. Sudden frost succeeding rains will more injuriously affect advancing salads than any other possible circumstance of weather. *Mushrooms*, take advantage of wet days for making fresh *Mushroom-beds*, and clearing out those that are spent; also, collect and prepare droppings for forming fresh beds by spreading them in a shed and turning them every day until they are sufficiently dried to prevent excessive fermentation after putting up. Look over root-stores occasionally to see that nothing is going wrong. Take advantage of a dry day to earth-up Celery, which now should be done effectually, as we are uncertain how soon frost may set in. Clear off all decaying leaves, &c., and stir the surface of the soil on dry days among growing crops.

FRUIT GARDEN.

Gooseberry, *Currant*, and *Raspberry* pruning and planting should be in progress. An adequate quantity of cuttings of the first two should be put in every season to provide for possible losses. The due preparation of borders for the reception of fruit trees should be completed, and the trees planted in the course of the month. Pruning and nailing may be commenced, a judicious system of stopping in the growing season renders the first-named operation a comparatively light and easy task.

FLOWER GARDEN.

Make the garden look as pretty and lively as possible during the winter, and this can be done with comparatively little trouble and expense after the first outlay, by filling those beds which are not planted with bulbs, or sown with hardy annuals, with dwarfed specimens of shrubs. The beds near the house would look best filled with *Laurustinus*, *Aucuba japonica*, *Golden* and *Silver-leaved Hollies*, *Arbutus*,

Berberis, evergreen Rhododendrons, and Box; those at a greater distance with Portugal and common Laurels, Arbor Vitæ, Phillyrea, &c., filling each bed with one distinct sort. We have frequently seen shrubs kept in pots for this purpose, but we consider this as unnecessary trouble. In removing them from their winter to their summer quarters, plant them in prepared beds in the reserve garden, and by regularly pruning back the summer growth of some, and pinching off the ends of shoots of others, a compact dwarf shrub will be obtained, and thus be in readiness for another year.

GREENHOUSE AND CONSERVATORY.

During the short dull days and long nights of this month, great care must be taken with all plants that have finished their growth to keep them free from all excitement, and pretty dry at the roots. Chrysanthemums will now be decorative plants here and will require attentive watering. Although they are very showy plants, and to see them arranged as to colour, size, &c., to advantage, they would require a house to themselves, nevertheless, it is necessary to be cautious that they are not introduced to such an excess as to overcrowd other and more valuable plants. All dead leaves to be picked off. A gentle fire to be applied during the day, which will allow of a free circulation of fresh air being afforded, and, by closing up early in the afternoon, will produce sufficient heat to resist the encroachments of ordinary frosts at night. Even when severe frosts occur, night coverings, if possible, should be applied in preference to fire heat. All hardwooded New Holland plants, such as Eutaxias, Boronias, Pimeleas, &c., are very susceptible of injury from cold drying winds; therefore, if they are wintered in the same house with the more hardy sorts of greenhouse plants, they should be accommodated with a situation free from draughts, with plenty of air from the top sashes in fine days. Choice Fuchsias that have been trained with a handsome leader should be preserved in the greenhouse, to be supplied with plenty of air and light to keep the wood sound and healthy, in preference to storing them away under the stage, or any other out-of-the-way place. Creepers to be closely tied that they may not interfere to an injurious extent with the amount of light in the house.

PITS AND FRAMES.

The cheapest and most effectual coverings for pits and frames are wood frames the length and width of each light, thatched 2 inches thick with wheaten straw. The frames to be made of well-seasoned deal, the sides, ends, and centre bar to be $1\frac{1}{2}$ inch thick by $2\frac{1}{2}$ wide, to be morticed and glued together, and small bars 1 inch square to be let in at about 1 foot apart to support the straw. Any two handy men will thatch one in a few minutes. A more temporary framework may be formed of shingles such as are used for making sheep-hurdles. Such coverings are neater, cleaner, cheaper, more easily put on and taken off, and more efficient than mats or any other covering at present in use. Indiscriminate watering must be avoided in the treatment of stock in pits and frames. Well-matured plants with no stagnant water about the roots, will resist such a low degree of frost as would be immediate death to others of the same sort that are succulent, of immature growth, and saturated with moisture. Hyacinths may still be planted in pots or put into glasses, and those which have been brought forward according to previous directions, may be forwarded in heat if required for early bloom. They can also be grown in pots of moss kept moist

—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

HAVE done little here, being anxious to collect turf and soil for future composts whilst the weather remains dry, as that makes such a difference in the carriage. Preparing for future planting, and especially opening holes for transplanting good-sized Larches and other forest trees, as, the holes being opened and the soil spread out, the latter will have the advantage of the first rains that fall, so that moist earth may go against the roots at least. The same should be done as respects preparing to plant fruit trees. In our circumstances it would be folly to plant anything until the ground be more moistened, or there be plenty of water at hand to supply the deficiency. In making the holes for

forest trees we never saw such dryness, and to great depths. Our prophecy in summer as to wells becoming dry in November is being too much verified from the accounts we receive from many quarters; and also, as we stated then, the taking the water in August somewhat freely, and the using it with great care and stint, have made little or no difference. Use it, or not use it, the water in the well would sink to the general level, and when dry we must either sink the well deeper or wait until the water rises.

The nearest running streams to us are $3\frac{1}{2}$, 4, and 5 miles distant, and we are from 250 to 300 feet above them. As these streams sink so do our wells, as we presume none of them are deep enough to go beyond the chalk formation. Many of us rejoiced in the water we obtained by the last rains, and we would just throw out the hint to those whose wells are low or dry to use even the rain water with care and economy, as if we have a wet winter, and get plenty of water in our tanks and pools, the spring will have come before these rains tell much on our wells. There is an old axiom, that almost every housetop will catch enough of rainfall to meet the wants of those who inhabit it; but then how few houses have tanks or reservoirs sufficiently large to hold the whole of the water that falls in the case of heavy rains. Even in the last rains there were many thousands of gallons that went from our walks and roads that would have been worth almost anything in summer. Many summers like the last will make us more careful of the water that falls from buildings at least, and we know of several instances where all overflows from the soft-water tanks will not be allowed to escape by the main drain as heretofore, mixed with all the house sewage, but will have a separate drain for itself into a reservoir, that shall be filled with pure water only. Instances also occur of parks and fields being so drained that the water shall be first emptied into a reservoir before the overflow finds its way into ditches or other outlets. As an instance of the scarcity of water this season, we may mention that buildings stood still for want of water to make mortar, or were continued at a ruinous cost to the contractor from having to cart water from a distance of four miles, and up and down steep hills.

With all the dryness, however, the late rains have brought up the Wheat beautifully, and vegetables are thriving well when once established. As a measure of precaution, broke some leaves over the heads of Cauliflowers to prevent a slight frost injuring them. Hoed and cleaned among young Onions, Spinach, Cabbages, &c. Looked over seed Potatoes, took up Carrots, planted Shallots and Garlic, earthened-up Celery, especially one bed of tall strong red, that requires endless work in comparison with the Dwarf Incomparable. Cut a good many of the Red Cabbage for pickling. Switched the walks hard to prevent them becoming a harbour for worms and slugs.

FRUIT GARDEN.

Looked over gathered fruit, removing any that are specked, just leaving a little air on the house, to prevent too much clammy sweating. We lately said that Pears ripened under glass were rather deficient in flavour, but some forward specimens, Marie Louise and Glou Morceau, were pronounced most excellent. We fear we overdid the little trees with bearing. A small garden of dwarf trees would be most interesting. Say a hard concrete bottom, soil 20 inches deep, trees well pinched-in, planted 5 feet apart, in rows 6 feet from each other, and a frame put over, so as to permit of covering with frigi domo. Heavy crops, summer pinching, and surface manuring, would keep these healthy and fruitful with but little necessity for root-pruning or frequent replanting. Pruned as we could find an opportunity, but wished we could do more, as it is more comfortable doing it now than in winter; but where attention could be given in summer, the pruning now will chiefly consist in removing or shortening the late summer and autumn growths.

Here is just one of those cases in which the amateur or the nurseryman who chiefly affects one department of gardening, should, and so often does, beat the gentleman's gardener. In the one case, everything may be done at the right time; in the other, one sort of work must often wait for another, unless in those extraordinary cases where labour is very plentiful, and one man, or set of men, may be set to attend to one department. Even a little extra work or job

will often throw all arrangements out of gear until the leeway can be brought up again.

In the orchard-house we swept and cleaned the leaves from the earliest part, and moved the trees in pots, setting them closer together, and will put litter among and over the pots by-and-by, and thus placing them close together will give room for lots of Geraniums, &c., from the beds, and for Cauliflower, Lettuce, and Endive for the winter. These trees have all been syringed with water at about 170°, after the smoking with Laurel leaves that we gave them. After the smoking we noticed some Ribston Pippin trees in pots, that had some *American blight* (*Aphis lanigera*), on them that did not seem killed by the smoking, the woolly matter, no doubt protecting them. These we have set out of doors as a preparatory step to thoroughly cleaning them top and roots, for on examining the roots we found there was as much blight below the soil as above it. We shall use strong lime water, or ammoniacal water, if we can obtain it, and then paint with Gishurst or sulphur and clay. We never had this insect on Pear trees but once, and that was on an Althorp Crasanne, and it existed at almost every bud. It had several scourings with lime water in the autumn, and was painted with clay and sulphur in winter, and the insect never made its appearance again. Turpentine, and even oil, will kill all the insects they touch, or shut them up from the air; but both are so far injurious to the plants. Thick lime wash would be as effectual for shutting them up from air for a time, and would do no harm.

Mr. Rivers, at least, ought to have the credit of doing away with the idea, that a man could only plant Pear trees for the benefit of his grandchildren. These Apple trees, and some Plums and Pears, were procured, as far as we recollect, as maidens, in the spring of 1863, and then potted. They were grown out of doors that year in small pots, and were fruited in-doors in the present season, and just bore too heavily to perfect a forest of buds for next season, but with a more moderate crop, they would continue year after year. Even as it is, there will be plenty of buds for a crop. If deemed necessary, therefore, by station planting, root-pruning, or summer pinching, the plant that is budded or grafted in the season of 1864, may produce fruit at least in 1867, and often in 1866, if you wished merely to say that such a thing could be done. The fruiting so early would, however, like taking a crop from Vines some fifteen or eighteen months from the bud, render future crops from the plant a very problematical affair.

For other matters see notices of previous weeks.

ORNAMENTAL DEPARTMENT.

Did a little to keep the lawn and the walks passable, have too much in hand to attempt to go over them every day. Will defer a good thorough cleaning in all parts until the most of the leaves have come down. Ash, Lime, and Elm leaves are now nearly down, but those of the Beech stick as if glued with bird lime, and Oaks are as yet rather green. The very sight of the tops of the trees now, will tell at once the nature of the tree as respects its rooting. All those whose roots extend chiefly along the surface, as the Ash and the Elm, have shown long ago the ripening effects of the dry summer, whilst the deep-rooting Oak shows no great difference from its state in ordinary years. In the fruit garden the state of the foliage will also often give a good lesson. Thus, where it has fallen, or is in course of doing so, nothing is wanted but a little top-dressing to increase vigour if required. Where the leaves are still vigorous and green, it says plainly enough that the roots are going down deep, and might be the better if their points were nipped off to lessen the vigour.

Took up a number of Geraniums from the beds, and placed them thickly under cover until we have time to look over them. Took up and potted a number of large plants that formed the centre of the pyramidal beds. Talking of pyramidal beds, we hope ere long to describe some pyramids of Calceolarias, &c., at Bentley Priory that did thoroughly surprise us, and that made a grand contrast with the usual beds.

We have not had time to finish our *Calceolaria cuttings*, but will be satisfied if we can do so before the old plants are touched with frost. We are glad that a correspondent has drawn our attention to our description of putting in these cuttings at page 338. That description is all right enough, with this exception that "10" is printed for "2." The little

sentence that puzzles him should read thus—"This season we plant them in rows 1 inch apart, and the rows are nearly 2 inches from each other." Last season the rows were only 1½ inch apart, but that was rather close, as the rooted cuttings became a perfect thicket early in spring. Had we plenty of room we would give the cuttings more of it—say from double to three times as much—and then we might save ourselves transplanting until we turned the plants at once into the beds. Our practice hitherto has been to take up these thick-set Calceolarias in March, plant out in beds where we can give a little protection, lift with balls in May, and transfer to the blooming-beds.

Another correspondent asks if it would not be better to take up now and pot or plant under glass nice stubby plants from the beds? We say, No, except you wish to have large plants as centres, or to grow in pots for early spring and summer blooming. For symmetrical plants in beds we prefer plants from cuttings inserted now, and a score of cuttings may be placed in the room that would be required for a fair-sized plant. "AN OLD BIRD" tells us, "My Calceolarias were all struck in the end of September, long before you put one in. I saw your Calceolarias in September, and they were only passable, whilst mine were extra good. I mean to keep to early striking." By all means: a man is right to use the bridge that takes him safest over the stream. We have struck late for many years, and never missed a fine bloom in September and onwards until this season; and that we consider entirely owing, not to the time the cuttings were put in, but to the great drought with which we were visited. Our object in late striking is, that the plants may have as little check as possible, and yet be kept in a small space until May. Older plants, and plants curbed and checked, we thought we had proved were apt to wear out, or only yield leaves instead of masses of flowers in the autumn. We are thoroughly convinced that, had we a stream or a large reservoir of water near us, our Calceolarias this autumn would have been as good as they usually are; still, that is no reason why another plan may not be as good or better than ours in different circumstances. A sense of honour must insist on detailing the very plans used, and mentioning failures as well as successes, otherwise these notes could be of no value or interest whatever. We like to hear everybody's opinion, and still more their practice; for even if we cannot adopt all these modes, we may still have the advantage of knowing that "in the multitude of councillors there is safety."

All bedding plants are now kept rather dry—that is those struck lately, and a little hay and litter is in readiness to throw over them in a sudden frost, as we are not ready to take many into our fruit-houses as yet. Commenced clearing out the conservatory, and fresh surfacing and cleaning the pots to go there. Chrysanthemums with us this season will be late and we fear rather inferior, in consequence of keeping them for two months banked-up against the north side of a shed very much shaded by trees. As we could not give them any water, this was the only shift we could resort to to keep them alive. They now look fair after being exposed since the rain came. Cinerarias, Primroses, &c., have had all the air possible, with shutting up partially at night. Shortened the climbers in conservatory to give more light, and cut the leaves from lots of fine-leaved Begonias that the pots may stand in another house anywhere in the shade. Plenty of air will be required for Croweas, Leschenaultias, Diosmas, Boronias, Gompholobiums, &c., but if they are near the front glass, the air should not pour at once on the stems. It is safest in winter to give top air rather freely, instead of giving so much by the front sashes. Pots should also be frequently rung with the knuckles to see that they are not over-dry, as dryness now is the fruitful cause of so many Camellia-buds dropping before expanding. Azaleas should also now be kept free from thrips, and if there is room might as well remain in a coolish house before the leaves drop that are likely to do so. Stove plants to bloom in winter, as Euphorbias, Poinsettias, and Justicias, should now have less water and more air until the flower-buds appear, when more water, heated, may be given to encourage strength and size of flower. It will now be time to trim creepers and twiners in this department. In summer they act as one of the best shades; but now light will be the chief thing that we cannot command, and, therefore, every advantage should be taken to get as much as possible of it.—R. F.

COVENT GARDEN MARKET.—NOVEMBER 5.

The market continues well supplied, and continental arrivals are heavy. Pines are far from plentiful, and prices are maintained. Grapes are sufficient for the demand, and include Dutch Hamburgs, but being inferior to home-grown fruit prices rule lower. New Lemons from Messina begin to arrive in quantity, and are of excellent quality; Oranges of the new crop are not yet coming in freely. Dessert Apples and Pears, both of the best and inferior quality, are very abundant; the former include Ribston, Newtown, Cox's Orange, and Golden Pippins, and King of the Pippins; the latter, Crassane, Duchesse d'Angoulême, Marie Louise, Glou Morceau, and great quantities of common Bergamots. Some fine specimens of foreign Apples and Pears are now to be seen in the fruiteers' windows, consisting of Uvedale's St. Germain, under the name of Belle Angevine, Catillac, Glou Morceau, and Easter Beurré Pears; and of Reinette du Canada and White Calville Apples.

TRADE CATALOGUES RECEIVED.

William Barron, Elvaston Nurseries, Derby.—Select Catalogue of Ornamental Plants. 1864-5.

Smith & Simons, 34 and 35, Argyle Arcade, Glasgow.—Catalogue of Gladioli, &c.

James Veitch, Royal Exotic Nursery, King's Road, Chelsea, London.—Descriptive Fruit Catalogue, 1864-5.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

SIX CHOICE PLUMS (W. K. H.).—Green Gage, Reine Claude Violette, Coe's Golden Drop, Transparent Gage, Kirke's, and Reine Claude de Bayav.

VINE-BORDER (W. D. P.).—Under the circumstances your predecessor did quite right in making the drain, but it would have acted better if it had been 2 or 3 feet deeper, so as to have been below the depth of the border. We approve of all you propose, but if on chalk you think the firm bottom necessary, we would concrete it by mixing lime and gravel with the chalk, and then rolling it firm when wet, and on that we would place fully a foot of lumps beneath the soil.

LARGE CROPS OF PEACHES.—We are informed that the whole length of the wall, producing the crop mentioned at p. 349, is 155 feet, by 10 feet high. Of the eight trees, three occupy 63 feet and the remaining five 90 feet. The produce of the former, respectively, is thus shown:—No. 1 (23 feet width), 350 Peaches; 2 (20 feet width), 400; 3 (20 feet width), 400; other five trees (18 feet each), 1350—in all, 2500 Peaches.

COATING FOR HOT-WATER PIPES (C. K.).—Before laying the pipes we coat them with black paint, composed of lampblack and boiled linseed oil sufficient to be of the consistency of thin paint. This is applied with a brush, working it in well so that every part of the iron may be covered, and it is allowed to become thoroughly dry before the pipes are fixed or jointed together. When the boiler is first set to work and the pipes as hot as they can be made, we give another coat with the same composition as thick as it can be put on, as it becomes much thinner when applied to the pipes. The oil paint applied on a hot surface finds the bottom of the uneven surface of the iron, and the heat being kept up until the paint is dry, it will last a long time without the iron rusting. We have it good at the end of ten years, and when it gives way we repaint the pipes as before whilst hot. Applying the paint to the pipes whilst hot creates an intolerable smell, and is not good for vegetation. The painting should therefore be done when the house is unoccupied with plants, and air being given the operator will be enabled to paint the pipes while hot, otherwise it is pernicious to breathe the atmosphere. If the pipes are not painted whilst hot, the paint is apt to peel off, but by heating the pipes are made thoroughly dry, and the paint runs to the very bottom of every hole and crevice; besides though there is a strong smell it is gone all at once. This is our mode of painting pipes in cool dry houses—as stoves and greenhouses. We have another for pipes in moist houses, it is the best for any description of iron exposed to wet, and we only name the preceding, as it is a practice we followed successfully before we were aware of the latter, which is to coat the pipes whilst hot with genuine red lead paint. This is the best coating for ironwork of any description that we have tried, and we therefore recommend it in preference to black paint, or any paint that has nothing anti-corrosive in it except oil. Two years ago we removed about 400 feet of four-inch hot-water piping that had been down thirty years, and externally they were as good as when put down, and this with a good coat of white lead paint. They had not been painted during that period. Whether white lead years ago was different from that which is now sold we cannot say, but it is certain that it will not at the present day preserve hot-water pipes from rust for half that period. Red lead paint, then, is what we recommend, and it should be put on whilst the pipes are hot, or they ought to be heated immediately afterwards and kept until dry, all plants being taken out of the house. Coating with gas tar is death to all vegetation if the pipes ever become hot, and the "blacking" of the foundryman is worse than useless, it is deceiving. For iron in or out of water, nothing is better for cheapness and efficiency than three good coats in the former case, and two in the latter.

VARIEGATED HYDRANGEA CUTTINGS (M. F.).—The best time to strike these is after the shoots have grown from 4 to 6 inches long, and have become a little hardened. This, under ordinary treatment, is in June, when the points may be taken off with three joints and a growing point, cut transversely below the lowest joint, the leaves there and at the joint above removed, and the cuttings inserted in sand a little below the second joint. They will strike either in heat or in a shady part of the greenhouse. Cuttings of the young growing points taken now will root freely if the pots are plunged in a mild hotbed.

STOVE PLANTS WITH YELLOW FLOWERS—EVERGREENS FOR SMOKEY LOCALITIES (*Constant Reader*).—Allamanda cathartica, grandiflora, nerifolia, and Schottii; Impatiens Jordoni which has yellow in the flowers; Hibiscus tiliaceus plena; Streblus reginae; and Hexacentris lutea. The most suitable shrubs are Rhododendrons of sorts, Aucuba japonica, and Hollies. Of smaller shrubs the very pretty Pernettya mucronata, Andromeda floribunda, Heaths, Kalmias, Ledums, and Berberis Darwini. Most annuals do well; and of biennials or plants treated as such, the Wallflower is pre-eminent for spring, and Canterbury Bells for early summer; and Sweet Williams are invaluable. To give you full information on all that relates to the management of smoky gardens, take more space and time than we can at present devote to it; but we hope to treat of the subject fully in an early Number.

VINES NOT THRIVING (York).—We think there is something pernicious in the soil, and that the border is quite rich enough. The indifferent colouring of the berries would indicate that the border is a little too rich rather than that it is not sufficiently so; or the unthriving state may be caused through an insufficiency of air, and the Vines carrying too heavy a crop. The reason of the soil being obnoxious to the roots is, that it is strong dark soil. It ought to have been sound light-coloured loam, the top spit of a pasture being best. To it we added one cartload of rotten manure to every four of soil; a cartload of brick and lime rubbish from an old building to every three of soil would have been better especially with dark strong soil. The crushed bones are good, and that was all we would have enriched the border with at the time of making, for the rotten manure could not retain its fertilising properties longer than a couple of years and then they are gone, and a close soap-like mass, in which Vine-roots do not like to run, is left behind. We presume the border is drained with rough stones to the depth of a foot, and that there is a drain along the border, and having an outlet, to take away the superfluous water. This being the case, and you being satisfied that the border is not a close, wet, soapy mass, but free and open, we would cover the outside border now with a few inches of litter to protect any roots that may be near the surface, and in February or March we would spread over the inside border 3 inches of partially decomposed short manure, and any nutrient the latter contains will be washed down to the roots with the waterings. We would also place from 6 to 9 inches of litter manure on the outside border at the same time, and any enriching matter which it may contain will be washed down to the roots by the rains that occur between then and June, when the litter may be removed, but the covering on the inside must be allowed to remain. This, if the border is not rich enough will do much to give the berries size, thinning them well when smaller rather than larger than Peas being another essential to obtaining large berries. Taking a moderate rather than a large crop, will do much towards securing proper colouring if accompanied by free air daily, and a little at night when the berries are colouring. On the other hand, if the border is wet and close, and the roots running badly in consequence of its not being drained, we can only recommend you to take up the Vines and make a fresh border, but you must draw your own conclusions as to that, as we can only form an opinion from the data furnished.

WIDENING VINE-BORDER (*Moonshine*).—You may add another yard to the Vine-border now. It will not injure but improve the succeeding crop. By all means place the Strawberries for forcing on the shelves in the cool viney, especially if they are to be forced early. You may stack them outside if you do not want to force them much, but they will ripen their buds much better in the cold viney.

AMARYLLIS LONGIFOLIA AND ROSEA.—**POTTING ISMENE CALATHINUM BULBS (Thorn).**—Pot them forthwith in turfly loam and leaf mould in equal parts, with a free admixture of sand. If the soil is moist do not water, but place the two former in a cool greenhouse, and the last in a warm greenhouse or cool stove. When they begin to grow, which they will do towards spring, water sparingly at first, gradually increasing the quantity as growth progresses, giving plenty in summer, reducing the quantity in autumn, and giving but little in winter. Keep in a light airy situation. In labelling, for *Amaryllis longifolia* write *Crinum capense*; and for *Amaryllis rosea*, *Crinum capense rosea*. They are nearly if not quite hardy in some parts of the country. They will grow in sheltered situations with a little litter over them in winter.

BOOKS (Sandhurst).—There is a cover for each volume of "The Florist and Pomologist," and it may be procured at our office. No "Annals of Horticulture" has appeared since 1849. "The Gardeners' Year Book" is published annually at our office, and contains the information you seem to require. (*A Young Gardener*).—There is no difficulty in the way of any bookseller, who has a trustworthy London agent, obtaining "The Wild Flowers of Great Britain." The Numbers appear regularly on the 1st of each month, and may be had direct from our office free by post for thirteen penny postage stamps. McIntosh's "Book of the Garden" is an excellent work for a young gardener. It may be obtained through any bookseller. It is in two volumes, price £1 11s. 6d. and £2 12s. 6d.

GAS STOVE IN GREENHOUSE (Ryde).—If, as you describe, all the fumes arising from the burning of the gas are conveyed by a pipe into the outside air, the stove may be safely used.

PEARS (G. I. L.).—Six Pears for your walls, to ripen from October to March, may be Beurré Diel, Beurré Rance, Giou Morceau, Passe Colmar, Ne Plus Meuris, and Winter Nelis.

DISEASED GRAPES (W. M. C.).—They are "spotted" as gardeners describe ulceration of the berry. As the crop is very heavy, the disease is probably caused by the roots not being able to supply sap sufficient to maintain healthy growth. The berries were too bruised to enable us to identify the variety. The roots are probably outside and too cold.

PLANTING FLOWER GARDEN (Alpha).—We think your proposed planting will do very well, though it would have been easier done with small beds. The design is pretty, but the fine figures in the centre will be drowned by the large ones round them. We question whether one bed of an octagon shape would not have looked better.

HOLES IN RHODODENDRON LEAVES (E. W.).—The leaves on the shoots enclosed are eaten or punctured through by the larvae of some insect, but what that has been we are unable to tell. Ants have nothing to do with the mischief. Had you looked at the Rhododendron foliage in July and August you would have found a dusky-looking caterpillar, about three-quarters of an inch in length, feeding on the then succulent leaves; and had it been picked off with the hand and destroyed, the mischief would, to a certain extent, have been mitigated.

BOXES COATED INSIDE WITH GAS TAR (A. H.).—If the tar was allowed to become thoroughly dry, or be absorbed by the wood before soil was put in the boxes, it will not injure the cuttings more than had the boxes been coated with ordinary lead paint. The roots, however, of all plants do not like tar, and we do not see why it was applied to the inside of the boxes. After the boxes have been used some time the tar will wear off; but if the plants will not grow in them satisfactorily you have no remedy but to take the boxes to pieces and have the tar planed off. We think this will be unnecessary, and that you are needlessly alarmed; for what we said of gas tar had no relation to such work as yours. It related to an entirely different subject; but yet no plant will grow well in a tarred tub or box.

ALOCASIA METALLICA AND LOUIII DRYING OFF.—NEPENTHES DISTILLATORIA (A Sunderland Amateur).—The Alocasias should have less moisture, less heat, and no more water during winter than is necessary to keep the soil barely moist. The temperature named is quite low enough, a minimum of 65° being most suitable. The bottom heat is right, but the sangers of water ought to be dispensed with at this season. The soil should not be allowed to become dust dry, nor ought the foliage to be allowed to suffer for want of water. A rest is essential to free growth next season. They should not be dried like Caladiums, but still rested by diminishing the atmospheric moisture, heat, and the supply of water at the root. They will do under the conditions named in the refuse or tan, preference being given to the former. The Nepenthes also should have a rest, and it will do under the same conditions as the Alocasias at this season. In winter it should not have so much moisture, nor heat, as when growing.

NAMES OF FRUITS (G. Taylor).—1, Beurré de Rance; 2, Forelle Pear; 3, Cellini; 4, Wormsley Pippin; 5, Nonpareil; 7, Reinette du Canada; 8, Golden Winter Pearmain; 10, Cellini. 2—1, Autumn Bergamot; 2—2, Passe Colmar; 2—3, Margil; 2—4, Trumpington; 2—6, Perry Pippin. (*H. B.*).—1, Dunelow's Seedling; 2, Herefordshire Pearmain; 5, Winter Greening; 6, Autumn Pearmain; 8, Court of Wick. (*Bushbridge*).—1, Fondante de Malines; 2, Sans Pepins; 3, Duchesse d'Angoulême. (*C. F. O.*).—1, Suffolk Thorn Pear; 2, Blenheim Pippin; 3, Ribston Pippin; 8, Mank's Codlin; 9, Wyken Pippin. (*H. P.*).—33, Emperor Alexander; 38, Nonpareil; 60, and 77, Court of Wick; 80, Herefordshire Pearmain. When numbers are not mentioned the specimens were not recognised. (*W. B. B.*).—**Pears.**—1, Beurré Diel; 2, Beurré Bois; 4, Beurré Diel; 6, Beurré de Rance. (*Apples*).—1, Hollandbury; 2, Dunelow's Seedling; 3, Scarlet Nonpareil; 4, Beauty of Kent; 5 and 6, Court Pendu-plat.

NAMES OF PLANTS (M. D.).—*Salvia Grahami*. (*Earn*).—1, *Corydalis lutea*; 2, Too young to name; 3, *Inula dysenterica*; 4, *Eupatorium cannabinum*; 5, *Nardus stricta*; 6, *Agrostis alba*; 7, *Spergularia rubra*. (*Orchidophilus*).—We see no reason why your plant should not be *Cattleya superba*, except that the flower is smaller than usual. (*Eskdale*).—1, Seems to be a *Tadescantia*, but the flower is completely smashed by the post-office stamp; 2, *Tritonia aurea*.

a stranger to things existing in the manufacturing districts of Lancashire, and my eye has always been upon poultry. First, in regard to shows, their uses and benefits. By placing prominently before the eyes of many persons beautiful specimens of the various breeds of fowls, it follows that at every show a desire arises in some of the lookers-on to possess such fowls as they behold. Also, in some who already keep good birds, there comes a wish to possess better. Hence each show increases the love of poultry. It is seed sown: therefore, shows should be encouraged by all who are lovers of, or who are interested in fowls. Again: shows are supported to a great extent by amateurs, more or less wealthy, who keep no account of expenditure, and, doubtless, sacrifice a considerable sum yearly, only being paid by the pleasure afforded; and who will say, that to such persons so situated, this is bad pay?

Next we come to a class of fanciers of special sorts of fowls, who having a name, in most cases well earned, make their hobby self-supporting, or even very remunerative. But poultry shows must for stability look to something else. To succeed permanently they must rest upon a broad commercial basis. Fancy alone will not do; whims even the most amiable seldom fill the pocket, though by the way, I am for hobbies without loss at any rate. In short, shows must pay, and they can only pay by introducing or encouraging those kinds of fowls which are profitable. Now, in the south, Dorkings are chiefly kept. Without doubt, the Dorking is the paying table fowl; its square build, its deep breast giving an extra cut, point it out as the very fowl for the cook. But fowls have another use—viz., they are producers of eggs, and hundreds of eggs are broken in our kitchens to every couple of fowls cooked. Now, in the south of England egg-producing fowls are not kept in sufficient numbers, hence French eggs, Jersey eggs, and Irish eggs, are imported in thousands, and who is to know when they were laid? By the way, I always date each egg with my pencil as I take it from the nest. It is such a comfort to see the date before you break the top at breakfast, feeling quite sure that all is right inside. Dorkings for farmers, and for others who supply the southern markets with table fowls. For them many prizes should be given at all southern shows. The egg question remains, and I am sure many may add to a living by the sale of eggs, who cannot breed fowls. I say, then, to our southern friends: your motto must be, "Hamburgs come south," and to bring them south offer many and good prizes. They, the Hamburgs, are our best egg-producers, and until the breed is made tolerably universal in England, there will be a deficiency in eggs. Fancy will do for other fowls, but Dorkings and Hamburgs do not rest on mere fancy. Surely the admirable qualities of the Hamburg cannot be known. At the Chippenham Show last year, not one pen of Silver-spangled was exhibited, and only two of Golden-pencilled and Silver-pencilled, and only one of Golden-spangled. Eggs are the want, and from Hamburgs alone can come the supply. Let them not, then, be regarded any longer as mere pretty fancy fowls. People who keep poultry for profit have something yet to learn. Dorkings for farmers; Cochins and Spanish for town yards; Hamburgs for eggs where a tolerable run is to be had.

In writing upon this subject I take care to keep quite clear of my own individual taste or fancy, and to take a broad view. Pet love blinds one eye at least. A fancier will naturally "write up" what he fancies. Lovers of Brahmans, those "wandering Cochins," or Cochins without one great benefit of Cochins—viz., being stayers at home, will write up Brahmans. All this is natural, but what we want is more eggs. I quite endorse the words of "A THOROUGHBRED SPANISH," "unless we cultivate and encourage the breed of everlasting layers, we shall not be able to compete with the French in eggs." So, again, I say, "Hamburgs of all kinds to the south." They are profitable where profit is needed. Other classes for fancy, and fancy prices; but Dorkings and Hamburgs for profit. Their excellencies are opposite, but keep the two, then the table will be supplied both with chickens and eggs. Let these two kinds be especially encouraged in all poultry shows in the south, this will bring both before the eye, and encourage both breeds; and I feel sure, both breeds being profitable, they will, if kept in great numbers, in turn support the show. WILTSHIRE RECTOR.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS IN THE SOUTH.

I SHALL be glad if I can be spared a little space to say a few words on this subject. I know England, north and south, pretty well; I may add east and west too, nor am I

POULTRY JUDGES.

I PERCEIVE by your Journal of the 18th ult., that the Poultry Club are dissatisfied with the Judges of the Show at Birmingham, and are about to memorialise the Committee, either to change the Judges or to add to them other Judges "who will have the confidence of the exhibitors."

What does this mean? I, as well as many others, were under the impression that the Committee at Birmingham had carried out a most onerous undertaking in a most satisfactory manner, and the number of the entries and the quality of the birds exhibited, are a proof of satisfaction on the part of a very large number of exhibitors. Query, can Judges be had who will please all the exhibitors?

I can give you an idea of what some amateurs expect of Poultry Committees. We have a Society in this city, and for the past four years we have had an annual Exhibition which has been remarkably successful, and the general details of schedule, pens, Judges, and other arrangements have been highly approved of by every one who has visited the shows; but we find our arrangements do not please some members of the Poultry Club, as we have received a letter from a Dublin gentleman stating that though he highly approved of the schedule, &c., yet he had lost all confidence in any "Irish Judges" that he ever met with, and, therefore, he suggested that we should place ourselves in the hands of the Poultry Club, adopt their rules, and get them to send us two Judges, adding that the Club would pay a portion of the expenses of the Judges, and that he would make a large entry, and, besides, would give £3 in money, or medal, for the best pair of fowls exhibited. You will understand that this disinterested offer was conditional on our placing ourselves in the hands of the Poultry Club. The Committee answered, that they had the most perfect confidence in the Irish Judges, but that in the present case they had already appointed their Judges; and as it so happened, both of them were Judges approved of by the Poultry Club.

This you would fancy ought to suit the gentleman in question; but no, the Judge appointed for poultry, though admittedly a first-rate Judge, was not the one he wanted, so he "hung fire," and as far as could be judged from his letter in reply, was inclined to back out of the matter. Some members of the Committee were of opinion that it ought to be explained to the gentleman in question, that the Society was composed of gentlemen who bred and exhibited birds not for profit or puffing, but to improve the breeds through the country, and for their own amusement; but the majority decided on making no reply, but they were unanimous in declining to relinquish the control of the Exhibition at the suggestion of an interested exhibitor, even though he was willing to pay for their doing so.

I am a fancier of Pigeons, and have read a very excellent work on them by Mr. Eaton. He says in it, that one of the ways to get prizes at a Show, is to "buy the birds from the Judges," and from the awards at some of the late Exhibitions (*vide* last Islington catalogue), I am inclined to agree with him; and as we have kept clear of any "jobbing" up to this time, we do not wish to commence now. The Judges appointed for the Show are both well known in London, Birmingham, and Glasgow, and in no instance have their awards been questioned.—A CORK "FANCIE."

SUNDERLAND ORNITHOLOGICAL SOCIETY'S FANCY PIGEON SHOW.

THE first annual Exhibition and competition of fancy Pigeons in connection with the above Society was held in the Central Hall, John Street, Sunderland, on the 1st, 2nd, and 3rd inst. Originally the Society was only intended for the immediate locality, but, encouraged by distant fanciers, the Committee determined to make it open to the United Kingdom. Since the discontinuance of the late Halifax Exhibition—an event deeply regretted by all true fanciers—there has not been a really first-class Pigeon Show, with the exception of that at Glasgow, now also given up; and it was therefore to supply this want that the present undertaking was inaugurated, more particularly as the town of Sunderland is of easy access to both English and Scotch

exhibitors. A fancier unconnected with the Society, anxious to lend a helping hand, undertook to offer a silver cup value £5, to be purchased by private subscription, and to be given as might be determined upon; and through the same channel John T. Lawrence, Esq., of Liverpool, sufficiently contributed no less than five similar cups to be offered for five different varieties. One of the Hon. Secs., G. R. Potts, Esq., gave a similar cup, which, with two more given by the Society, enabled the Committee to offer no less than nine silver cups, value £5 each, for competition, in addition to nine classes with prizes of £2 and £1 each, as well as a selling class. Acting on the suggestion of Mr. Lawrence, the entry fees were fixed low—namely 5s. each pen, except for the selling class, the result being that most of the very best birds in the kingdom were sent for competition, numbering upwards of 230 pens.

All the birds were ranged on a level, the Glasgow circular pens being used on the occasion. Some of the birds were scarcely through the moult, but we understand that next year the Exhibition will be held at a later date, so as to enable the whole of the various specimens to be in greater perfection of feather. Under the able management of the Hon. Secs., Messrs. G. R. Potts and J. R. Robinson, the arrangements were most complete and admirably carried out in every respect, their exertions being crowned with entire success; and we hope the Society will continue to receive the encouragement to which it is so eminently entitled.

In the class for the best pair of *Almond Tumblers* there was an entry of twelve pens. Mr. Peter Eden won the cup with a splendid pair, good in all points. Mr. Else secured second position with a pen excellent in feather, but not so perfect in head and beak.

In the class for *Carriers* the cup was also awarded to Mr. Eden for a remarkably good pair of Duns. Mr. Colley was second and highly commended with good Blacks. In Mr. Else's highly-commended pen (Black), the hen was out of condition.

For the best pair of *Pouters* eight pens were sent, the competition being extremely close. The cup was awarded to an extraordinary pair of Yellows, belonging to Mr. George Ure; the hen being unquestionably the best of the colour ever exhibited. Mr. Eden took second with very fine Blues, and Mr. Potts received very high commendation for a capital pen of the same colour, the cock being slightly out of order; while Mr. Ure's Reds, a splendid pair, were highly commended.

Mr. Lawrence's cup for *Barbs* brought some first-class birds of this variety, more particularly in cocks, perhaps four of the best ever seen together competing. The cup was awarded to Mr. H. Beldon for Yellows of most unusual merit; the second went to Blacks, the cock with the drawback of having yellow eyes.

The *Fantail* class was an excellent one, numbering fifteen pens. Mr. Else secured the cup (Mr. Lawrence's), with a plain-headed pair, small and fine, good in carriage and condition; a nice pair were second; and seven pens, including a good pair of Laced, received notice, proving the closeness of the competition.

In *Jacobins* ten pens were sent for Mr. Lawrence's cup, which was taken by a beautiful pair of Reds, very small and fine, an equal match, with good hood and chain, belonging to Mr. Esquillant; fine Blacks were second; while Reds (two pens), and Blacks were highly commended.

In *Turbits* fifteen pens were exhibited, Mr. Lawrence's cup being awarded to a splendid pair of shell-crowned Reds, clean and fine, belonging to Mr. S. Shaw; a small pair of peaked-crowned Blues were second; two pairs of good Yellows and a pair of Silvers receiving high commendation.

The *Owls* formed a beautiful class of a dozen entries, Mr. Lawrence's cup falling to Mr. Sanday's fine pair of Whites, shown in capital condition, with the exception of the hen being slightly picked on the head. Mr. Eden took second with very good Blues, a good match; and the Blue cocks in each of the pens shown by Messrs. Else and Fielding were highly commended, as well as a pair of Whites belonging to the latter.

In the class for *Trumpeters* fourteen pens competed. The cup, given by distant fanciers, was won by Mr. J. R. Robinson with a splendid pair of Black Mottles, good in rose

marking and size. Mr. Shaw was second with the same colours, his famed old Mottled cock not being so well accompanied as formerly. First-class Whites received very high commendation, and good Whites, Mottles, and Blacks were highly commended.

Blue Powters formed a class of seven pens. Mr. G. Ure had first with an extraordinary pair in every point. Mr. Cochrane's second-prize birds were also very good. *Black Powters* only numbered four entries, but each was worthy of a first prize, and such a class was never, we believe, brought together. Mr. Potts was first with birds of great length. Mr. Eden was second. Mr. Ure's highly-commended pen contained a particularly good cock. *White Powters* were not numerous but good. Messrs. Eden and Ure divided the prizes in the order named. In any other colour of Powters, Mr. Ure had first with a pair of Reds of extraordinary length; and Mr. Potts' second-prize pen contained one of the best Red hens known.

Black Carriers mustered eleven pens, but Mr. Eden out-distanced competition with remarkably good birds, and took both prizes. In the class for *Dun Carriers*, Mr. Colley took both prizes with capital representatives.

Balds or Beards formed a pretty class. Very fine Blue Beards were first, and Blue Balds second. The latter were unusually good in head and beak, and clean cut, but slightly deficient in matching, the hen being unequal in colour to the cock.

In the class for *Mottles* or *Kites*, Mr. Eden had both prizes with his wonderful Black Mottles, four pens receiving notice.

Any other Variety Class numbered fourteen entries. The first prize went to Mr. Shaw's Blue Shields, shown in fine condition. The Rev. C. Spencer was second with Swiss Pigeons. Isabels, Satinettes, and Brunswicks were highly commended.

The *Selling Class* brought no less than sixty-five entries. Black-headed Nuns were first; Helmets second; and Fantails third.

The following is the prize list:—

TUMBLERS (Almond).—First and Cup, P. Eden, Salford. Second, F. Else, Westbourne Grove, Bayswater. Highly Commended, P. Eden; G. Ure, Dundee; F. Else.

CARRIERS.—First and Cup, P. Eden, Salford. Second, T. Colley, Sheffield. Highly Commended, T. Colley; F. Else. *Cock*.—Highly Commended, W. Massey, Gedney.

POWTERS.—First, Cup, and Highly Commended, G. Ure, Dundee; P. Eden, Salford. Very Highly Commended, G. R. Potts, Sunderland.

BEARDS.—First and Cup, H. Beldon, Bingley. Second, W. B. Van Haasenbergen, Newcastle. Highly Commended, P. Eden, Salford. *Cock*.—Highly Commended, W. H. C. Oates, Besthorpe, Notts.

FANTAILS.—First and Cup, F. Else, Bayswater. Second, J. R. Jessop, Hull. Highly Commended, T. Ridpath, Rusholme; A. P. Leite, Manchester; J. Thackray, Petergate, York; H. Yardley, Birmingham; G. Ure, Dundee; F. Else; R. T. Jarvis, Dartford.

JACOBINS.—First and Cup, F. Esquiant, Oxford Street, London. Second, T. Ridpath, Rusholme. Highly Commended, S. Shaw, Halifax; F. Else, Bayswater; F. Esquiant.

TURBITS.—First and Cup, S. Shaw, Halifax. Second, J. R. Robinson, Sunderland. Highly Commended, S. Shaw; H. Yardley, Birmingham.

OWLS.—First and Cup, G. H. Sanday, Nottingham. Second, P. Eden, Salford. Highly Commended, P. Eden; J. Fielding, jun., Rochdale. *Cocks*.—Highly Commended, J. Fielding, jun., and F. Else, Bayswater.

TRUMPETERS.—First and Cup, J. R. Robinson, Sunderland. Second, S. Shaw, Halifax. Very Highly Commended, F. Else, Bayswater. Highly Commended, W. B. Van Haasenbergen, Newcastle; W. H. C. Oates, Besthorpe, Notts; S. Shaw; F. Else; J. R. Robinson.

POWTERS (Blue).—First, G. Ure, Dundee. Second, J. Cochrane, Glasgow. Highly Commended, H. Beldon, Bingley; H. Brown, Walkley, Sheffield. Commanded, G. H. Ellis, Leicester; P. Eden, Salford.

POWTERS (Black).—First, G. R. Potts, Sunderland. Second, P. Eden, Salford. Highly Commended, G. Ure, Dundee. Commanded, H. Beldon, Bingley.

POWTERS (White).—First, P. Eden, Salford. Second, G. Ure, Dundee. Highly Commended, P. Eden; R. Fulton, Deptford.

POWTERS (Red, or Any other colour).—First, G. Ure, Dundee (Red). Second, G. R. Potts, Sunderland.

CARRIERS (Black).—First and Second, P. Eden, Salford. Commanded, H. Martin, Glasgow; A. P. Leite, Manchester.

CARRIERS (Dun or Any other colour).—First and Second, T. Colley, Sheffield. Highly Commended, F. Else, Bayswater; F. Esquiant, Oxford Street, London.

TUMBLERS (Balds or Beards).—First, W. H. C. Oates, Besthorpe (Blue Beards). Second, F. Esquiant, Oxford Street, London. Highly Commended, J. Fielding, jun., Rochdale (Blue Beards); T. Ridpath, Rusholme.

TUMBLERS (Mottles or Kites).—First and Second, P. Eden, Salford (Black Mottles). Highly Commended, W. H. C. Oates, Besthorpe, Notts (Red Mottles); J. Peroval (Kites). Commanded, J. Fielding, jun., Rochdale (Black Mottles); F. Else, Bayswater.

Any VARIETY NOT PREVIOUSLY NAMED.—First, S. Shaw, Halifax (Blue Shields). Second, C. Spencer, Attleborough (Swiss Pigeons). Highly Commended, Rt. Hon. Countess of Derby, Prescot (Isabels); H. Yardley, Birmingham (Satinettes); H. Beldon, Bingley (Brunswicks).

SELLING CLASS (Any variety).—First, W. Johnstone, Carlisle (Nuns). Second, H. Yardley, Birmingham (Helmets). Third, T. Rule, Durham (Fantails). Highly Commended, T. C. Taylor, Middlesborough (Nuns); J. Bell, Newcastle (Tumblers); H. Yardley (Tumblers); J. R. Robinson, Sunderland (Carriers). Commanded, J. W. Edge, Birmingham (Turbits); J. Key, Beverley (Turbits); J. Pringle, Newcastle (Balds); W. Massey, Gedney (Dragons); J. Bell (Tumblers); H. Yardley (White Trumpeters and Yellow Magpies).

The Judges were Mr. T. J. Charlton, of Bradford, and Mr. D. Wolstenholme, of London, and their decisions gave general satisfaction.

LIGURIAN BEES DETERIORATING INTO BLACK BEES.

THESE are a long review of the *Times*' "Bee master's" book in the *Morning Star* of the 25th of October, which, no doubt, you and many of your readers will have seen; but we shall feel much obliged to Mr. Woodbury if he would say if it is a fact that the pure Ligurian bee changes into the common black bee in course of time, as the reviewer states. But I have no doubt that many of your apiculturists would be much obliged to Mr. Woodbury if he would review this book, and also the *Star's* reviewer in your Journal.—A. W.

[The *Star* reviewer is quite wrong in stating that "pure Ligurians change in the course of generations into the common British variety," if he meant that this change can be effected in any other manner than by interbreeding with the black species. I am, in fact, pretty certain that this latter is what he really did mean, although he was rather ambiguous in his mode of expressing it. There is no doubt whatever that the tendency to cross between the two varieties is the great difficulty to be encountered in introducing the Ligurian to a country so well stocked as England is with the common black bee. Still I know cases, and could point to one in particular, where a Ligurian stock was introduced into an apiary of common bees some years ago, and permitted to increase by natural swarming only. The result has been, as was to be expected, a considerable number of hybrids; but even now some stocks continue to present all the characteristics of pure Ligurians.

I regret that I cannot comply with "A. W.'s" request by reviewing either the book or the *Star* reviewer, since I agree with nearly all the conclusions at which the latter has arrived, whilst I feel precluded from noticing the so-called "bee-book" itself by the fact that a great part of it consists of mere personal vituperation directed against—*A DEVONSHIRE BEE-KEEPER.*]

BEES ARE NOT CARNIVOROUS.

BELIEFS however mistaken, and statements however absurd when honestly made are entitled to respect, and should not be cast overboard without investigation, as the groundless superstitions of some Jonas Jackson. When "RUBY" gravely informed us that bees, like flies, fed on flesh and fowl, or possibly garbage and carrion, I would have looked upon him as gravely facetious, had not the Editors of the Journal assured us that the alleged fact was supported by most respectable testimony.

Besides, the Ligurians bore a striking resemblance to wasps in their outward appearance, and why might they not also resemble them in their habits? But, unhappily for antiquated notions, neither black bees nor Ligurians, so far as I can perceive, are disposed in the very least degree to be carnivorous.

About three weeks ago I presented two hives with pieces of roast beef, pheasant, and thrush. Some pieces were simply roasted, others were basted with honey, or immersed in syrup of sugar. Those saturated with honey and sugar were the only pieces that the bees cared about, the others were quite unheeded; although a process of disintegration went on in the pieces made attractive by honey and sugar, not one particle was eaten. What was wanting in the original size of the pieces was found under the drainer on the bottom of the feeding-trough, in granules reduced to about the size and form of eggs laid by the queen bee. Had I not taken the precaution of using a trough protected by a bar-drainer, the particles would doubtless have been thrown down on the floor-board, or carried out. As soon as the

honey and syrup were extracted the pieces were abandoned, and they have been lying within the hives from the time I inserted them till now, as uncarred for as a cast-out maggot.

Bees, under certain conditions, when gnawing flesh with a view to its removal, may make use of the juice; but I am persuaded no amount of fish, flesh, or fowl, would preserve the lives of a famished hive a single day. It is the saccharine matter on which bee-keepers must depend for the safety and prosperity of their bees. Next to honey, the best food and most easily procured for feeding purposes, is lump sugar melted in the manner recommended by Mr. Woodbury, the proportions being 3 lbs. of sugar to 2 lbs. of water.—R. S.

JOINING LIGURIAN BEES TO ENGLISH OR BLACK BEES.

In the Journal of October 11th, "A. W." says he joins stocks of bees by fumigation. Now, it is decided by bee-masters that fumigation by whatever process it is accomplished, more or less injures the bees. The great secret of joining bees or uniting stocks is, after having removed one of the queens, to liberally sprinkle each lot to be joined with sugar and water. The bees immediately commence lapping it up. The stock to be joined should then be well sprinkled and shaken down in a mass upon the top of the bars. The bees of each lot commence cleaning one another, and the assistance rendered makes them friends and proves the old saying, "A friend in need is a friend indeed." If the bees joined are from the same apiary, it is well to confine them in the hive until the next night, when very few bees will go back to their old place.

I have this last month joined twelve stocks of common bees to my Ligurians, and in some cases have joined the Ligurian bees to a black stock; but I of course destroyed the black queen in every case. I have not lost on an average more than a dozen bees in each stock joined, and have not had a single failure. It is all nonsense about peppermint scent and all other nostrums.—WILLIAM CARE.

[You appear to have been very fortunate in uniting bees this autumn. Following precisely the same course, you may be equally unfortunate next year, as no means have yet been discovered by which we can be absolutely certain of avoiding a quarrel. Be not too hasty in condemning the use of peppermint-scented syrup. We believe it to be serviceable in confounding the sense of smell by which bees are supposed by many to recognise each other. No harm, at any rate, can result from its use.]

BEE-HIVE PROTECTORS.

I HAVE been a bee-keeper for several years, and during that time have tried various contrivances for protecting my hives from the weather. Bee-houses I have discarded on account of the large number of bees which I generally lost during the autumn from spiders' webs. Some mornings I have found as many as a dozen bees entangled in the meshes of the spiders' webs, if I omitted to clear the houses early in the morning before the bees ventured out. Large straw hives I have also used for coverings, but they also want something to cover them, or during very wet weather the rain is apt to soak through and cause dampness in the hive which they are intended to protect. Some bee-keepers recommend covering the hives with earthenware dishes similar to milk-pans. I have also used these, but have found it necessary to have stakes fastened in the ground to secure the covers to, or off they would have come the first windy day. The stakes and the string which are required to keep this description of cover on the hives make it look a very untidy affair. Well, after having tried almost everything that I could think of, I came to the conclusion that something in the shape of a large hive would answer the object I had in view, and could be made to look ornamental; but as I work my bees on the depriving system, I was at a loss how to contrive a cover which would keep my bees free from damp in the winter, and without removing it enable me to work them in summer. After some little reflection I determined to have a large clay pot made in the shape of a bee-hive, but with the top moveable like the top of a sea-kale pot. Having some business to transact with

the manager of the Southborough brick field at Kingston, I explained to him what I required, he readily understood me, and made some pots with moveable tops sufficiently large to enable me to put a cap on in summer, and then make use of the top of the cover to protect the cap from getting wet. At the present time I am, of course, using them to cover the stocks only, and to my mind they are an ornament to the garden, but I think that they will be much more so in the summer, when I am using the small straw caps, and the cap covered with the clay top. I have shown the covers to many friends who are interested in bees, and they all pronounce them to be good, and I think that if they were generally used we should not hear of so many hives being annually lost through damp. I intend painting the covers with stone-coloured paint, at present they are as I received them from the potteries.—J. W. T., Wandsworth, Surrey.

THE "TIMES" BEE-MASTER'S BLUNDERS.

A good deal of Dr. Cumming's nonsense about bees is tolerably harmless; and had it not most unfortunately appeared under the authority of the *Times* newspaper, would no doubt have been passed over with the silent contempt which no real bee-keeper could help feeling on reading the letters. In your notice of his lecture at Liverpool you quote him as saying, "Swarms always take place between twelve and three o'clock," and you pass over this most mischievous misstatement without correction. Every one who really keeps bees must know that if he never began to watch before twelve o'clock most of his swarms would be lost, and I cannot imagine a piece of information more likely to ruin the hopes of a beginner. I may as well add that bees on fine days, at swarming time, may be expected to come off at any time from 9 A.M., and even earlier, up to 3 and even 4 P.M.—FRANK GRANT.

FOUL BROOD.

ON reperusing my notice of foul brood in pages 343 and 344 I fear I have not been sufficiently explicit in disclaiming all participation in the absurd notion that this disease is due to the mode in which the queens of infected stocks deposit their eggs. If this were really so, no mode of treatment would avail in mitigating the disease so long as the faulty queen was retained. I need hardly say that so far from such being the case, a change of queens is not even of the slightest service. My object was merely to draw attention to the fact that in more than one instance diseased brood has been found to be inverted, and to inquire how far this circumstance had come to the knowledge of other observers.

—A DEVONSHIRE BEE-KEEPER.

DEADLY EFFECTS OF THE YEW TREE.—It appears from recent facts which have come under our notice that the Yew when taken into the animal stomach becomes fatal in its poisonous effects, which proved to be the case a few days since. Some men employed by the Llanelly and Swansea Extension Railway Company had occasion to fell a Yew tree that stood in the way of some cuttings on land in the occupation of Mr. John Morgan, Bolgoed, where some cattle belonging to that gentleman happened to be grazing on a field into which the tree fell, when unfortunately one of his best cows, in full profit, browsed some of the Yew leaves, which in a few hours proved fatal. A post mortem examination was made, and proved that among the contents of the stomach was a quantity of Yew in a high state of fermentation. Only a few days since we heard of a similar occurrence to a horse belonging to Mr. J. Bailey, of Littleton Drew.

TO PREVENT CATTLE FROM JUMPING.—At the last meeting of the Am. Inst. Farmers' Club, the following novel way of preventing cattle from jumping fences was promulgated. Its parentage is good:—"We lately learned a curious remedy to prevent steers from jumping fences, which is so easy of application, and appears so effectual that we give it to the public. It is simply to clip off the eyelashes of the upper lids with a pair of scissors, and the ability or disposition to jump is as effectually destroyed as Samson's power

was by the loss of his locks. The animal will not attempt a fence until the eyelashes have grown again. Of this we are informed by Samuel Thorne, the great breeder of Dutchess County, who assured us that he had tested it upon a pair of very brachy oxen. As it was of great value to him he hopes it will be tried by others."—(Canada Farmer.)

RAISING THE CALF—A HINT TO THE CRUSTY.

"ISN'T she a beauty, father? Only see what a handsome little head she's got, and how fat she is. I don't believe there's another calf in the town that can beat her."

"That's just what I think, Nathan," replied the farmer, without raising his eyes from his axe-grinding. "She'll do to kill by Saturday. Joel Smith wants part of her. We might as well sell the whole, for the head and pluck will be as much as we shall want this hot weather."

"Don't have her killed, father. Why can't we raise a calf as well as other people? Ford said when he was getting the hay yesterday that it was a shame to have all of old Brindle's calves killed, for she was the best breed of cows anywhere about. You know what a pailful of milk she gave all last summer, and that you got the premium on her butter."

"Well, I know all that, boy, but she would cost more than a hundred dollars before she would bring a cent. If anybody is fool enough to raise them when they can buy them all ready for milk at 20 dols., to 30 dols., let them do it. I'm too old for such calculations."

"Perhaps it is so, but I can't bear to have her killed. If you will let her live I will take all the care of her, and raise a bed of carrots for her to eat next winter. Why, she shan't trouble you."

"Your mother wants the milk right away, to make all the butter she can this month, and if we keep the calf she must have it two or three weeks longer. Then, what will you do with her this summer?"

"Oh, let her go in the pasture with the cows. She can eat a little clover now; I fed her with some yesterday. Ford said she would eat almost anything in a little while."

"It would make pretty work to have her run with her mother; she'd take all her milk each day."

Here Nathan was at a loss for another plea, when he happened to think of the little orchard, and proposed to put her in there. But his father told him she would eat the sour apples that fell off and spoil her teeth. He thought he could put Bossy in her pen at night, and get up early enough in the morning to pick up the apples. Several other objections were raised and met with the same boy-earnestness, when his father told him to go to his work and he would see about it. This "see about it" gave the boy some encouragement. He thought it would be a good plan to get his mother on his side. When he went into the house he found her so busy in soap-making that all he could get from her was, "Just as your father thinks best about it; I shall want the rennet, for I am going to make cheese in dog-days. The butter isn't worth much that's made then." Here was something new for Nathan, who did not know what rennet was for, or where it came from. When his mother told him it was the calf's stomach, he thought it would be an easy matter to get one of some of the neighbours who never made cheese. A few mornings after this conversation, farmer Gaines asked his wife what she thought of letting Nathan raise the calf. Her reply was, "You know best about it, father. I should like to have the boy gratified, if it don't give you too much trouble." What an excellent lesson this reply was to all dictatorial, unthinking wives, whose opinion must rule, or there will be a drizzle or storm within and without.

Nathan heard and said nothing about Bossy for a week, expecting every day that she would have her throat cut, loving her all the more with the fear of losing her. In the meantime the farmer had been resolving the subject in his mind, and came to the conclusion that if keeping the calf would make an early riser of his boy it would be worth while to try it, for the summer at least, when he thought he would get enough of taking care of her, and be glad to have her sold in the fall to the drovers. No farmer could have been more pleased with a present of the best Devon or Ayrshire cow, or seen from her a better prospect of wealth, than did Nathan Gaines when his father told him he might keep the

calf, if he would take good care of her, and raise all the roots she wanted for next winter. All this he promised to do, and anything else that was desired. Never had he so high an opinion of his father before. This unexpected favour made obedience a very easy matter. Every morning Nathan was up bright and early to take care of his calf and look after his carrot-bed, so as to be ready for any other work. Bossy soon became so much of a pet with the family that she never went hungry. Even the farmer, who feared so much the cost of raising her, seemed to enjoy giving her an extra bite as he went to feed his horses, and often Nathan found bits of bread and other morsels from the table, which she liked very much. When autumn came the calf had done so well there was no danger of her being sold. Every one who saw her said she was the largest and best one of the season. Farmer Gaines thought his boy had done enough more work to pay for all she ate, and if it took a ton of hay to keep her through the winter, he had no idea of having her sold. Nathan's interest in the calf never flagged, neither did he allow her to be any trouble to his father. We will pass over three years of her life, when we find young Brindle giving as much milk as her mother, and will soon take her place in the barn, for old Brindle's cow-life is almost over, and she will in a year or two be consigned to the beef-barrel.

Farmer Gaines has never regretted that the calf's life was spared, for he has a better cow than he could find elsewhere; and by gratifying Nathan in this act the boy had formed habits of carefulness and industry which will be worth a fortune to him. No father loses anything by giving the boys reasonable indulgence, even if the cost is not always repaid in cash.—(Ohio Farmer.)

OUR LETTER BOX.

SILVER-PENCILLED HAMBURGH COCK'S TAIL (R. W.).—It should be white with a black tip to each feather. A black tail would be a disqualification. Any approach to it is therefore a defect.

WASHING FOWLS (Fancier).—As a rule it is only the outer feather that is dirty, therefore it is only that which requires washing. Wash with soap and water, then put the bird in a basket partly filled with hay or soft straw, and let it stand before a fire till dry.

DR. CUMMING AND VIRGIL.—I noticed in your Journal of last week that "A CONSTANT READER" had called your attention to Dr. Cumming's saying in his lecture on bees that "Virgil has given an account of bees in one of his Eclogues," which should be "Georgics." In justice to Dr. Cumming, I beg to say that the mistake was my own, in inadvertently transcribing Eclogues, instead of Georgics, in the report, for which I beg to apologise.—EATON CLIFF.

TOMATO SAUCE.—Break the tomatoes into an earthen pan or jar, bruise, and sprinkle with a handful of salt, and let them stand twenty-four hours; then stir them up, and put them into an oven closely covered, and let them simmer very gently for about two hours; then wash them through a sieve till the seeds are quite dry. Add some spice according to taste, and a root of garlic chopped fine, and a teaspoonful of dry sweet herbs to every quart of tomato. Put into the oven again, and let the whole simmer till it attains the thickness required. The spice stated in the recipe is a quarter of an ounce of cloves, a quarter of an ounce of mace, half an ounce of allspice, and one ounce of ginger, cut in slices, to each quart of tomato. If you prefer it you can substitute Cayenne pepper for ginger.

Tomato Sauce to keep through the winter.—Put a peck of tomatoes, six large onions, one or two capsicums, and six shallots, into an earthen crock, and place it in an oven, when the bread is taken out; leave them until quite soft; then, when cold, pass them through a fine hair sieve. Add pepper and salt, and boil the purée until sufficiently thick, about the thickness of very thick cream. When cool, bottle for use in wide-mouthed bottles, covering the corks with sealing-wax or resin. If at any time it appears to ferment boil it again, adding a little more pepper and salt.

"A GARDENER'S WIFE" can recommend the following recipe for making tomato sauce, to which horseradish can be added if the recipe is liked:—When quite ripe take off the stalks and wipe the fruit quite dry, put into a slow oven or stew-pan till soft, then put through a hair sieve to separate seeds from pulp. To every pound of pulp add one pint of gooseberry vinegar, twenty large shallots, half an ounce of garlic, half an ounce of capsicum, half an ounce of ground white pepper, and 2 ounces of salt. Boil the whole until the shallots and garlic are soft, rub through the sieve again, and give another boil. If too thick, add more vinegar; bottle when cold. If gooseberry vinegar cannot be had common will do.

LONDON MARKETS.—NOVEMBER 7.

POULTRY.

There is a good average supply of poultry, and a very bad demand; prices are consequently low. Partridges, as usual, are becoming scarce, but the supply of Pheasants is large.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 48.3°, and its night temperature 34.2°. The greatest heat was 62° on the 16th, 1840; and the lowest cold, 18°, on the 15th, 1848. The greatest fall of rain was 0.87 inch.

DECORATION OF THE FLOWER GARDEN
IN WINTER AND SPRING.

(Concluded from page 369.)

3RD.—YELLOW-FLOWERING PLANTS.

UNDoubtedly the handsomest of yellow spring flowers is *Alyssum saxatile*. It is now in bloom with me on rock-work, and it, with *Aubrieta deltoidea* and *Arabis alpina*, promise to bloom abundantly throughout the winter. Being in patches of several superficial feet, and running over large stones, these have the appearance of little mountains of blue, white, and yellow. *Alyssum saxatile* is a free-blooming evergreen undershrub, forming gorgeous beds of yellow in April and May. It is readily propagated by cuttings taken off with a little of the old stem, or a heel, or slipped like Sage. It is also raised from seed. There is a variety called *A. saxatile compactum* which is very desirable on account of its dwarf close habit and profuse blooming. The variegated form (*A. saxatile variegata*), forms a lovely golden mass in early spring, its foliage being also very ornamental. All the above thrive in well-drained soils of any description, but best in sandy loam.

Alyssum montanum is a dwarfer free-blooming yellow than *A. saxatile*, being only half the height of that species. It is increased by division. Under the name of *A. alpestre* two distinct kinds are sold—at least, I had one *A. alpestre* that had flowers more curious than ornamental, appearing in June, and under the same name another, which was a lovely mass of golden yellow in April and May. It was also much more dwarf and compact. The latter is, I think, the same as that sold by nurserymen under the name of *A. alpestre*, and it is, I believe, the *A. Marshallianum* (Andrews), or *A. alpestre* of Bieberstein, which is from the Caucasus, whilst the other is to be referred to *A. alpestre* of Linnæus, it being from the mountains of Southern Europe. However this may be, the *Alyssum alpestre* that I wish to note for spring decoration does not exceed 6 inches in height, differs little from *A. montanum*, flowers most profusely in April and May, and is increased by division.

Alyssum orientale differs little from *A. saxatile* if both are not identical; the variegated form of it is, I am sure, not different from *A. saxatile variegatum*. They are pro-

pagated by cuttings, like sandy soil, and are very handsome in a mass.

Primroses. The most handsome of spring yellow-flowering plants is the Primrose, than which nothing makes a lovelier bed, and if it be edged with the Aucuba-leaved Daisy, nothing can be finer. The double form (*Primula vulgaris plena-sulphurea*), is unquestionably a diamond of the first water. It makes fine beds if edged with *Stachys lanata* alone, or with the latter planted alternately with the Aucuba-leaved Daisy.

Adonis vernalis. A mass of this old herbaceous plant is gorgeous in April and May. It grows about a foot high, and thrives in all well-drained soils, doing best in sandy loam or sandy peat. It is increased by division. There is another pretty kind (*A. volgensis*), little different from the preceding.

Onosma tauricum, than which few plants have brighter yellow flowers, is fine even as a specimen, but much handsomer in a mass. It grows from 6 to 9 inches high, flourishes in light soil, and is increased by division. It is, however, somewhat difficult of propagation, but at Well Head, Halifax, Mr. Baynes propagates it by layers, and it may there be seen in a pot looking as handsome as anything well can be. *O. arenarium* is a rather taller species, and equally handsome.

Double Marsh Marigold. For wet soils we have the Double Marsh Marigold (*Caltha palustris plena*), which is a gorgeous mass of gold, the flowers individually like buttons, and it grows with its roots in soil under water. It should be grown in wet soil, and is increased by division.

Cheiranthus alpinus is a dwarf yellow-flowering Wall-flower, not more than 6 or 9 inches high, a perennial undershrub, increased by cuttings taken off with a heel, and inserted in July in sandy soil in a shady border.

Yellow Wallflower. The yellow variety of the common Wallflower (*Cheiranthus Cheiri luteus*), is very fine, and may be increased by inserting cuttings or slips with a heel in sandy soil in a shady border, keeping moist till well rooted. Plants may also be raised from seed, which should be sown in May in an open situation, transplanting the seedlings when large enough into nursery-beds in lines 6 inches apart, and the plants 3 inches apart in the rows. Under this treatment, with a rather light soil and copious waterings in dry weather after pricking out, they make fine plants by autumn, when they may be removed with balls to the places assigned to them, or transplanting may be deferred until spring. This, however, is best done in autumn, as the plants bloom much stronger; but a reserve should be provided to fill up any gaps that may occur.

Cheiranthus Marshalli, a splendid variety, is the next best yellow bedder to *Alyssum saxatile* and *Adonis vernalis*. The flowers are a good yellow, but to make sure of the stock being true it is best propagated from cuttings; for seedlings sport much, as do those of the common Wallflower, though it occasionally comes pretty true from seed. It makes a fine bed, and is fragrant withal. Propagated by cuttings or seeds the same as the common Wallflower.

Saxifraga cymbalaria, or Ivy-leaved Saxifrage, forms dense erect tufts from 3 to 6 inches high, with succulent ivy-shaped shining leaves, surmounted by a profusion of pale yellow blossoms, spotted with orange at the base. It prefers moist situations, but will grow anywhere, seeds most freely, reproducing itself in great abundance, and is evidently an annual. Seeds sown in June make splendid plants for blooming in the following year. For the ledges and fissures of rockwork this is a gay plant during the early spring and summer months.

S. arctioides is a yellow-flowering Swiss pigmy, of no mean appearance in a bed, but is better suited for rockwork. It is increased by division.

Anthyllis vulneraria is pretty enough for a bed, but flowers rather late, still it is worthy of a place. It is only the common Houndwort, however, common enough in chalky pastures, and therefore many people will not care to have it. It is increased by sowing the seeds when ripe, and by division when there is anything to divide.

Hippocratea comosa, another English weed, and a very pretty one, not exceeding 6 inches in height, makes a neat bed. It is an evergreen trailer, and increased by division.

Uvularia perfoliata, and *U. flava*, are nice dwarf plants, increased by suckers taken off with a little root. They flower finely in May.

Narthecium ossifragum is another plant for wet soils. It would, however, be all the better if it bloomed a little earlier. It is a curious little thing, occasionally blooming well early in the season. It is increased by division.

Eremurus spectabilis, which I have not seen for a long time, strikes me at the moment as being likely to form a fine yellow bed to flower in May; it is increased by offsets.

Gagea lutea, a pretty little bulbous plant, a native of our woods, *G. stellaris*, a Scandinavian, and *Sternbergii*, a Swiss, make pretty beds in well-drained soils.

Trollius americanus. This really gorgeous species which is less than the magnificent *T. europaeus*, must not be omitted. Both will grow anywhere, and are of easy management. Division.

Ranunculus illyricus, and *R. pygmaeus* (often confounded with *R. montanus*, which is taller, and does not flower so early) make splendid beds; but none rival *R. gramineus*, which is one of the many fine things to be found in Wales, the double form (*R. gramineus flore pleno*) being the best of all. Division.

Doronicum austriacum, and *D. scorpioides*, are nice plants, growing about 1 foot high. *D. plantagineum*, and *D. pardalianches*, are about double the height of the two preceding, the latter being the well-known Leopard's Bane, so plentifully found in many meadows. Division.

Gratiola aurea is a very pretty dwarf plant, not exceeding 6 inches in height, and it will grow anywhere. Division.

Last in my list of yellow-flowering plants are *Primula auricula lutea*, which is excellent for a yellow bed; *P. elatior*, *P. Pallasi*, a dwarf species, and *P. Palinuri*, an excellent small kind from Naples, rather tender, but doing well in sheltered situations in sandy loam.

4TH.—PURPLE-FLOWERING PLANTS.

Aster alpinus is a free-flowering purple, but somewhat late, and it is not always to be depended on. It grows about 9 inches high. Division.

Lamium orvala is a deep purple, the plant somewhat tall, and it flowers rather late. Division.

Myosotis purpurea, like the last, is another tall plant, having a very handsome flower much in the way of Chicory. Division.

Orobous vernus is a plant worthy of being planted in a mass. It grows well in any ordinary garden soil, attains a height of about a foot, and should be increased by parting the roots.

Ramonda pyrenaica, a dwarf plant, from 3 to 6 inches high, flowering in May, is a good purple, thriving well in sandy soil.

Tussilago alpina, about 6 inches high, is a pretty light purple, increased by division.

Hyoscyamus orientalis has purple flowers, with a tinge of yellow, grows a foot or 18 inches high, and prefers light soil. Division.

H. physaloides is a dwarfer and hardier species, a better purple, and flowers more profusely. Division.

Primula carniolica is a pleasing purple, and not more than 3 or 4 inches high. *P. viscosa*, *villosa*, and *nivalis* are pretty, and worth more attention than is at present accorded them. *P. purpurea*, a species from the Himalayas, is, I think, likely to prove the finest purple Primrose yet introduced. When we have added *Soldanella alpina* and *montana*, *Aubrieta deltoidea* and *purpurea*, which are blue rather than purple, we have no more purple flowers for spring, except *Viola odorata purpurea*.

5TH.—REDS, INCLUDING REDDISH PURPLES.

The lack of blues and purples is fully compensated for by the richness of the flowers of this division; they are not, however, so bright in colour as desirable, nor so profuse in blooming as the whites and yellows.

The Hepaticas, double and single red, are amongst the foremost of spring flowers; in fact, Hepaticas form a charming class by themselves, and being amongst the earliest of spring flowers they deserve even more attention than is accorded them. *Hepatica triloba rubra* (single red), and *H. triloba rubra plena* should be associated with Snowdrops and Crocuses, as they flower earlier than the majority of spring-flowering plants.

Saxifraga oppositifolia is a charming plant, making one of the loveliest of beds. It should be raised as described for *S. oppositifolia alba*. *S. crassifolia*, and *S. cordifolia*, are also desirable. They are increased by division.

Lychnis alpina, from the Scotch hills, *L. viscaria*, and the double form of the last, are charming plants that must be hunted out of their native wilds, and planted in our gardens. Light soil is preferable for them. Division.

Hutchinsia stylosa is a somewhat tender plant, dwarf and very pretty. It is increased by division.

Erinus hispanicus, a pretty dwarf plant, is very fine, and of free growth, though it does not exceed 6 inches high, and is increased by division.

Epimedium alpinum is a creeper, growing some 9 inches high, and having blood red flowers in April. It is a native of this country. Increased by rooted cuttings, and will grow anywhere, but best in wet soils.

Phlox pilosa, *amœna*, and *verna*, are pretty flowers, flourishing in light loams, and growing about 6 inches high. All make nice bedders, and are increased by division.

Linnæa borealis, than which few plants are prettier, likes dry ground, and is an evergreen trailer, increased by division. It is a native of Scotland, and does not grow more than 3 or 4 inches high.

Arabis rosea is a glorious plant for filling a bed with fine rosy flowers in spring. It is as hardy as any *Arabis*, and is readily increased by division and seed.

Cortusa Matthioli is one of the many lovely plants of the order Primulaceæ. It grows 6 inches high, produces fine rosy red flowers, and is increased by division.

Ajuga reptans rubra, a dwarf plant, 6 inches high, is suitable for wet soils, but will grow anywhere. It has pretty flowers in May, and like most hardy plants is increased by division.

Canadian Columbine (*Aquilegia canadensis*), is a nice plant, with a pretty reddish orange flower. It may be raised from seed or propagated by division. It prefers sandy soils, doing best in sandy peat.

And why not have a bed of Geraniums in spring by planting *Erodium alpinum*, which does well in all sandy soils? It is dwarf, has handsome foliage, and is propagated by cuttings and division; also, a bed each of *Geranium nepalense* and *G. tuberosum*, which bloom in May in warm situations, and are then amongst the handsomest of pink flowers. Sandy loam is the best soil, and a stock may be obtained from cuttings or by division of the roots, which is a slow but sure process.

Silene acaulis, a little plant common on some hills in Scotland, makes a neat mass, but is at least a month too late in blooming, though it does sometimes come early. It is propagated by division.

Pulmonaria grandiflora, a fine pink, and *P. officinalis* will deck a couple of beds, and will grow anywhere. *P. virginica* is as good as either of them but a little taller. Division.

Melitta melissophyllum of our woods, grows about a foot high, it being beaten by the Swiss form (*M. melissophyllum alpina*), which is dwarfer and more profuse-blooming. The flowers are flesh-coloured and fine. Division.

Heuchera glabra, grows about 1 foot high, has very pretty pink flowers in May, makes a lovely bed, and is increased by division.

Saponaria ocymoides with its dense cushions of pink, makes one of the loveliest of beds. It is an evergreen trailer, doing best in light soils, and is increased by cuttings, which root freely in sandy soil in a shady border.

To these may be added the rose Siberian Violet (*Viola Krockeri*); *Paeonia anomala*, with red flowers; *P. decora*, purplish red; *P. lobata*, with rosy flowers; the double form of *P. tenuifolia* being fine, and *P. tenuifolia*, good. Nor must we omit *Corydalis bulbosa*, a pretty pink-flowering tuberous-rooted plant, which prefers lightish soil, but will grow anywhere, and when we have a bed of *Dielytra spectabilis* in pots, which is most excellent, only it blooms quite late enough, we must rely on Primroses for the rest that is to be done towards decorating the flower garden with red flowers in spring.

Of these the pretty reddish purple varieties of the *Primula auricula* are excellent; *P. Allioni*, *P. altaica*, the lovely *P. cortusoides*, the pretty *P. ciliata*, and the handsome Danish *P. stricta*, are all excellent. The double red Primrose of gardens (*P. vulgaris plena-rubra*), the double purple, and others in red shades are excellent in beds by themselves, as margins to others, or associated with other plants, nothing being prettier than a bed of double red Primroses edged with white double Daisies; and, last of all, the different forms of *Polyanthus*, whether single or double, are very fine.

As regards other plants, we have Pansies in many shades of colour, and many other really good early-flowering plants might be found, and brought into use as spring ornaments to the flower garden if, only, all of us would set to in earnest, and having found a plant blooming early communicate its name to others through the medium of the horticultural press.

Having the plants named, or others equal to them, in stock, and they should be stiff strong plants grown in an open situation, and not huddled together in some out-of-the-way corner, they are to be taken up with nice balls. Whether they be deciduous or evergreen plants, herbaceous, bulbous, or tuberous-rooted, they must all be taken up with some earth to them, at least as much of it as adheres to the roots, be planted immediately (closely so as to cover the surface if evergreen, or so as to do so if deciduous by the time they flower), in their several positions, doing the work carefully so as not to break or injure either the tops or roots. This may be done any time in mild weather from October to the middle of February, and when the ground is in good working order so as to insure neatness. It may be necessary to water after planting, but not often, once at planting being enough to settle the earth about the roots. This even is misapplied if the weather be at all wet or showery. A reserve of most kinds should be kept back to fill up any blanks that may occur during the winter, the beds being made good by the beginning of March.

By the last week in May, or first week in June, all of them, owing to their places being required for summer bedding plants, must be cleared off, and this is done in the same manner as at planting, taking them up with a ball, and removing them to their summer quarters, which should be an open yet sheltered sunny situation. After removal water well, especially if the roots are bulbous or tuberous, and continue to do so according to the weather until the plants become well re-established. Such as have done blooming and are in a fit state for propagation should be divided, as in the case of *Primulas*, or cuttings or slips should be inserted, as in the case of *Alyssums* and *Wallflowers*, or seeds sown if propagation is to be effected in that way. If bulbous-rooted they are best divided at the time of planting, if that be in October, but if later it should be done when the foliage decays.

G. ABBEY.

NOTES ON A COLLECTION OF GRAPE VINES

FRUITED IN POTS IN THE SUMMER OF 1864.

In the month of March, 1864, I took from my collection of Grape Vines, one plant of each of forty-four sorts, and placed them in a cool viney with the view of testing. 1. Their suitability for pot culture. 2. Their quality. 3. Their comparative earliness. The pots were placed on slates so that

the roots could not escape from the pots; the rods were trained up the rafters of the house, and the plants fully supplied with weak manure water. The whole of the plants were but one year old and of equal strength.

I shall proceed to describe them in the order in which they ripened. Those marked B, are Black; W, White Grapes.

1. Chasselas Vibert, W. Ripe August 26th. Produced six medium-sized bunches of large well-flavoured berries. It was the earliest and best of the Sweetwater race, and set better than any other.

2. Grove-End Sweetwater, W. Ripe September 10th. Produced six small bunches, rather loose. Berries large. First-rate.

3. Muscat de Juillet, B. Ripe September 10th. Produced three small bunches. Berries small.

4. Chasselas de Falloux, W. Ripe September 10th. Produced ten large bunches. Berries large. A good pot Vine.

5. Chasselas Bulberry, W. Ripe September 10th. Produced ten large bunches. Berries of medium size; flavour good.

6. Almeria, W. Ripe September 10th. Produced ten large bunches. Berries large. A good pot Vine.

7. General Della Marmora, W. Ripe September 10th. Produced ten large bunches. Berries large; flavour above the average. Quite first-rate.

8. Royal Muscadine, W. Ripe September 10th. Produced eight medium-sized bunches. Berries of medium-size. First-rate.

9. Foster's White Seedling, W. Ripe September 13th. Produced eight large bunches. Berries large. A hardy good Grape.

10. Muscat St. Laurent, W. Ripe September 13th. Produced six small bunches. A rich-looking Grape of good flavour. Hangs well.

11. Chasselas Duhamel, W. Ripe September 16th. Produced four small bunches. Berries large. Flavour very good.

12. Chaptal, W. Ripe September 16th. Produced ten large bunches. Berries of medium size.

13. Black Hamburg, B. Ripe September 18th. Produced seven large bunches. Berries large. Still one of the best for pot culture.

14. White Frontignan, W. Ripe September 18th. Produced six medium-sized bunches. Berries of medium size. First-rate.

15. Buckland Sweetwater, W. Ripe September 18th. Produced six large bunches. Berries large. A good pot Vine.

16. Trentham Black, B. Ripe September 20th. Produced one small bunch with large berries. Of doubtful value for pot culture.

17. Chasselas Musqué, W. Ripe September 20th. Produced seven medium-sized bunches which did not crack; ripened well. Berries large; of exquisite flavour.

18. Esperione, B. Ripe September 20th. Produced ten large bunches. Berries large; flavour good. A first-rate pot Vine.

19. Pope's Hamburg, B. Ripe September 20th. Produced ten large bunches. Berries large. A first-rate pot Vine.

20. Black Frontignan, B. Ripe September 26th. Produced nine medium-sized bunches. Berries small. Not so good as the White Frontignan.

21. Muscat Hamburg, B. Ripe September 26th. Produced seven small bunches; shanked. Berries large; flavour exquisite.

22. Alicante (French), apparently Black St. Peter's, B. Ripe September 26th. Produced ten small bunches. Berries of medium size; flavour first-rate.

23. Madeira Muscat, B. Ripe September 26th. Produced three small bunches. Berries small, of exquisite flavour.

24. Perle Impériale, W. Ripe September 26th. Produced six large bunches. Berries large, of a rich golden hue; skin thick; flesh solid; flavour good. Hangs well.

25. Sarbelle Muscat, B. Ripe October 1st. Produced eight small bunches. Berries of medium size.

26. Purple Constantia, B. Ripe October 1st. Produced eleven medium-sized bunches. Berries of medium size; flavour exquisite. A good pot Vine.

27. Ahbee, W. Ripe October 1st. Produced four large

bunches. Berries large and handsome; slightly acid. Not so good as Raisin de Calabre.

28. Black Prince, B. Ripe October 6th. Produced three large bunches. Berries large. First-rate.

29. Chasselas de Fontainbleau Rouge Hâtif, B. Ripe October 6th. Produced seven small bunches. Berries small.

30. Muscat Noir de Jura, B. Ripe October 6th. Produced six medium-sized bunches. Berries large. A good hardy sort. Foliage beautiful in autumn.

31. Ingram's Prolific Muscat, B. Ripe October 6th. Produced seven small bunches. Berries small; flavour good.

32. Raisin de Calabre, W. Ripe October 6th. Produced three large bunches. Berries large and handsome. Flesh firm; flavour good. Hangs well.

33. Chavoush, W. Ripe October 6th. Produced three large bunches. Berries large. A fine-looking Grape.

34. Cambridge Botanic Garden, B. Ripe October 6th. Produced three large bunches. Berries large.

35. White Romain, W. Ripe October 10th. Produced ten medium-sized bunches. Berries of medium size. A good pot Vine.

36. Lady Downes' Seedling, B. Ripe October 10th. Produced seven medium-sized bunches. Berries large. A good pot Vine.

37. Black Monukka, B. Ripe October 15th. Produced four large bunches. Berries large, conical, and stoneless; flavour fine.

38. West's St. Peter's, B. Ripe October 18th. Produced six small bunches. Berries large. Quite first-rate.

39. Morocco Prince, B. Ripe October 20th. Produced eleven medium-sized bunches. Berries large. Quite first-rate.

40. Burchardt's Prince, B. Ripe October 20th. Produced eight large bunches. Berries large. Not sufficiently known and valued. Quite first-rate.

41. Kempsey Alicante, B. Ripe October 20th. Produced seven large bunches. Berries large. A good pot Vine.

Three varieties—Trebiano, Mill Hill Hamburgh, and Duc de Malakoff, bore no fruit.

The large bunches averaged 1 lb. in weight; those of medium size three-quarters of a pound; the small half a pound.

Now, for the application of these facts. With an ordinary greenhouse or viney a good supply of Grapes, White and Black, and of various flavour, may be secured for at least three months in the year at a very moderate cost of money and trouble. The entire weight of fruit gathered off the forty-one one-year-old Vines may be fairly set down at rather more than 2 cwt. Had they been placed where the roots could have been passed through the holes at the bottom of the pots, I doubt not that a heavier crop would have been secured; but I could not conveniently accomplish this, nor did I deem it necessary for my purpose.

Reasoning from this and previous experiments, for seven of the best pot Vines I should choose for weight—Esperione, Pope's Hamburgh, Chasselas de Falloux, Chasselas Bulberry, Almeria, General Della Marmorata, and Chaptal; for an additional seven—Black Hamburgh, Morocco Prince, Burchardt's Prince, Foster's White Seedling, Purple Constantia, Kempsey Alicante, and White Romain. Chasselas Vibert should be added for its earliness.—WILLIAM PAUL Waltham Cross, N.

ROSES PAST, PRESENT, AND FUTURE.

HOWEVER desirable the plan proposed by Mr. Curtis (and anything on the Rose, from one bearing that name ought to be listened to), I fear it is impracticable. There is not the same spirit in France as to exhibiting that there is here; for although the Central Society of Horticulture has held meetings somewhat similar to the Floral Committee of the Horticultural Society here, yet very few of the growers, even around Paris, thought it worth while to send their seedlings. Something of the kind was suggested to me some years ago, but I could not do it.

I had hoped to have continued my dissection of the Rose lists this week, but have been prevented; and I find that there is a mistake in the printing of the first paper. In speaking of M. Eugène Verdier's Roses I am made to say I have selected "these"; it should be "three"—the two Hybrid Perpetuals mentioned, and Maréchal Niel, Tea, which

I shall speak of by-and-by. As far as my judgment and knowledge of the Paris Roses are concerned, Duchesse de Medina Coeli, Duchesse de Caylus, and Rushton Radclyffe, will be the leading varieties. In a letter received from M. Charles Verdier the other day he speaks highly of Duc de Wellington (Granger) as being a very fine Rose.

What a splendid season it is! I have cut blooms this month which were first-rate; and have now two beautiful flowers of Devonensis and Madame Joseph Halphin, taken from standards, in the vases on my chimney-piece—quite refreshing on Lord Mayor's-day. Although the term Hybrid Perpetual is abused, yet to be able to cut blooms of Senator Vaisse, Général Jacqueminot, &c., as I have done from my small collection, in the month of November, entitles them to our gratitude.—D., Deal.

LARGE CROPS OF PEACHES.

MR. DALY (page 348), expresses a wish that some remarks may be made on his communication about his crops of Peaches. If the Englishman referred to means the undersigned I make no apology for taking precedence, as I am entitled to correct an error. The Peaches gathered from my three trees this year were 560, and not 510. Of the quality of these Peaches the best proof is their winning the first prize at Blandford, Baron Hambro being second, and that they were good enough to send to Mr. Eyles for the *déjeuner* at the Kensington Exhibition in September. I say quality with emphasis, because it is simply ridiculous to talk of quantity without quality. The *quantitas vocis* is a good thing, but the *qualitas rei* is a better thing. The *qualitas* of a Peach depends (supposing the sort to be good), rather on the size of the Peach than on the number of Peaches on the tree. The heaviest crop that I ever grew on my three trees, which were, and are still, about 52 or 53 feet wide by 9 feet high, was 1024. What was the effect of this unwise crop? The next year I had only 197 Peaches. From this I learnt that to overdo is to undo.

I do not speak in defiance of Providence, still less will I lay a charge against Providence if I fail; but I firmly believe that I shall be able to gather next year 500 Peaches from the above trees. This will make 4500 Peaches in nine years off two trees now in their forty-sixth year, and off one tree now in its twenty-ninth year, the men being alive in this parish who remember their being planted. After the crop of 197 Peaches I believe that the next crop was 775. Lord Portman's present gardener, Mr. Leach, came that year to inspect the trees. I had taken off a vast quantity, and had left on the unwise number of 1200. Mr. Leach said, "I advise you to take off one-half at least." Well, I am never prejudiced or obstinate. I therefore, though they were thoroughly separated before, thinned them down to a number that allowed me to gather 775 good Peaches, not tasteless witherlings. I fancy that the next year the crop gathered was about 468. I say fancy, because I have not my references here. This leads me to diverge.

This summer my old and valued friend Mr. Shipp, bookseller, of Blandford, came here to see the Roses and eat Strawberries. I hardly need say that the two hallucinated him. Being here, he said, "I wish you would let me have your articles already published. I will cut them out and paste them into an album free of cost, with thanks for the amusement and edification that I have received from them." Hence, as he has my periodicals, I must be forgiven for an erratum.

To return. I think that in an article on Peaches in my "Florist," now in Blandford for the above purpose, Mr. Powell, of the Royal Gardens at Frogmore, has said that three Peaches per square foot are sufficient. I am not expert enough to say much on this matter; but I firmly believe that what we gain in numbers by overcropping we lose in weight, size, and quality this year, and next year in quantity and quality. I believe yet further, that where we leave on six Peaches the Jerseymen and Frenchmen leave on three.

Mr. Daly's crops in 1863 and 1864 are certainly very great; but, will he not say in due time, "There is nothing like moderation and a good annual supply?" What sort of land has he? It must be a land of "nuggets" to stand for any length of time such heavy cropping. I for one shall

be glad to know what is the crop of 1865. I am very glad to see that he manages his Peach trees as regards protection much the same as myself; but I fear our error is a leaning towards overcropping. I do not attribute the loss of his leaves and the non-setting of his fruit to the same causes as he does—quite the contrary. It was not from keeping the sheets on, but probably from having left them off on “mild nights,” when the frost caught him napping. In bad weather I leave them on for days and nights together. When will people learn that the leaves of a Peach tree are more tender at their unfolding than even the blossoms?

I went this year to review my oldest friend's large garden near here. What did I see? A capital crop of Peaches protected by tiffany; but the north-east wind and frosts had gone through the tiffany, and blistered the leaves almost to a totality. The leaves looked as if a mole had burrowed between the cuticles. These blistered leaves must drop; what is to become of the tree and fruit till new ones spring up? The tree, being deprived of lungs at such a time, must suffer in its general health, and the fruit can never be of first-rate quality. Pines, Grapes, Ferns are well done at my friend's: the two things wanting there are glass casings and more pumps. In such a large garden, with so many trees, it is of no use to talk of sheeting, which is better than any glass casing for the general health of the trees, unless it can be drawn up and let down by rollers. Where there are only a few trees, and where the amateur takes particular interest in them, sheets will (put on at 4 p.m. and taken off at 10 a.m., and only left on in discourteous weather), beat everything. The trees are much more healthy, thus protected, than when permanently stowed under glass. Had I a glass casing I would, in torrid summers, remove every bit of it after the danger is over. The mess made under glass arises chiefly from a want of free circulation of air, and from deficient watering.

In conclusion, I must say that it is not the fault of gardeners that their Peaches fail; they cannot do impossibilities. A Peach tree is as much an exotic as a Muscat. The Muscat is protected, but the poor Peach tree, blossoms and leaves, is suffered to “rough it.” The wood this year is nicely ripened, and the leaves drop fast. I am like Mr. Micawber in the Fleet prison, hoping some good thing will “turn up!”—W. F. RADCLIFFE, Rushton.

CULTURE OF THE ALPINE STRAWBERRY.

NOTWITHSTANDING the excellence of the Alpine Strawberry as a dessert fruit, comparatively little attention has been paid to its cultivation. This is evidenced by the fact, that we too often see it grown in some out-of-the-way place, or trampled under foot, as if kept for the mere sake of having the variety. Consequently, it is no wonder we so often see such small fruit from this valuable Strawberry. Knowing its value, and that its culture should be more cared for, I offer to your readers a few notes on the mode of cultivation I have practised with good results.

To obtain seed, procure some fine and well-ripened fruit; bruise it, and spread it over some thick paper for drying. Place it out in some dry airy place, not allowing the damp to affect it; when dry scrape it off from the paper, and store it away till the following March; then sow in pans, just covering the seeds with light soil. Place the pans in gentle heat until the seedlings are up and sufficiently strong; then gradually harden them off. Never allow the plants to become too dry. When sufficiently hardened, prick them out, in a rich and open piece of ground, in rows 9 inches asunder, allowing 4 inches between the plants in the rows. Keep all runners cut off, and give water when required. Nothing more will be wanted but keeping the plants free from weeds during summer, until the following spring, then a piece of ground in an open position must be provided, highly manured, dug, or if well trenched all the better. Choose a fine day for transplanting the plants to their fruiting place—a care that cannot be too strongly recommended for all planting.

The ground being ready for planting, mark out the rows 2 feet apart; then with a plunging-fork take up the plants, and set them in their new quarters a foot apart in the rows. Neatly finish off the ground, and never allow weeds

to encroach. Keep all runners cut off during the summer, which will enable the plants to swell their fruit better. Watering is one of the essentials for the Strawberry, therefore it must be duly done. Another point is to cover the surface round the plants with some kind of material, such as flints, broken tiles, or slates. I use flints, which not only allow the water to pass more readily to the roots of the plants, but keep the ground near the roots more moist.

Following the above hints, one may have ripe Alpine Strawberries from the time the other larger kinds have done bearing until the end of October, and often later; and thus the labour bestowed on this Strawberry will be amply compensated, and especially to those who, like myself, have many dishes to make up every evening.—C. P.

VISITS TO GARDENS PUBLIC AND PRIVATE.

MESSRS. F. & A. SMITH, DULWICH.

As some years had elapsed since I had been able to visit the well-known nursery at Dulwich, I was not sorry of the opportunity afforded me in the month of September of again going through the extensive houses which cover so large a space in this nursery. When I was there before, the nursery was in a transition state. It had formerly been one from which Covent Garden Market had been largely supplied with those plants which are not indeed

“born to bloom unseen,

And waste their sweetness on the desert air;”

but are born to die an untimely death, killed by the dust, and dirt, and gas, and fire heat of London rooms. The Messrs. Smith were then getting out of this, and at the present time the houses and pits that used to be filled with such plants are occupied with the choicer and more valuable ones that are comprised in a good nursery stock. The success which has attended their efforts at hybridisation in the many beautiful varieties of Cinerarias, Azaleas, &c., which they have from time to time brought before the public show that they are not novices at such things; while their magnificent show of Balsams has always been acknowledged as about the finest in the kingdom, and, as I witnessed, there is no retrogression in this department.

It would be impossible for me to describe (and were I to do so it would be a useless attempt), the whole of the plants contained in this extensive establishment; and I shall therefore select a few such salient points as seem to me to especially mark it. Thus their collection of Zonale Geraniums is probably as extensive as any in the kingdom, comprising every variety of home and foreign growth; while their own establishment has afforded them thousands of seedlings, many of them of great promise, especially amongst those Tricolor variegated ones of which Mrs. Pollock is the type, and on which there is now so great a run. The Messrs. Smith have largely hybridised in this class, and some of their results are very curious. Selecting one of the plain yellow-leaved sorts, such as Cloth of Gold, for the mother plant, they have hybridised with some of those broad-zoned varieties of which there is a plentiful assortment, and thus the combination is obtained; while the bright flame, varying from light pink to brilliant crimson, is found in a large proportion of the issue. In some the marking partakes more of a marbled character, being irregularly disposed over the whole leaf. Then, again, there were plants which were absolutely double, half the plant was green and half variegated. Nor was this confined to the leaves only: the stalk was in the same way divided, one half of it being green, the other marked. Whatever may be the cause of variegation, be it disease or not, some light might surely be thrown upon it, by such curious results as these, in the hands of a botanist. Then, again, some plants run up quite green throughout. To the eye of an inexperienced person they would seem to be useless; but Mr. Smith waits, and strangely enough they break, from the base of the stem very frequently, quite variegated. Others again, which show symptoms, very faint it may be, of variegation, when potted into richer soil break into colour. While alluding to this subject I may mention that I have this autumn put in a large quantity of cuttings of Mrs. Pollock, and that I have not lost one. My plan is to put three or four cuttings in a pot, and place them in the sunny part of my little greenhouse.

I mention this because some persons have remarked to me that it is a queer thing to propagate. Amongst other bedding Geraniums I noticed as very good Prince of Orange, an orange scarlet, and two others (under numbers), which promise to be acquisitions—20,64 and 58,64; the former of these is a very fine flower.

Azaleas form a large feature in this establishment, upwards of ten thousand small plants alone being grown, and, as we know, many fine sorts have come from here. Flag of Truce fully bears out the high estimation formed of it when it was first exhibited. The foliage is handsome, while the purity of the white exceeds that of nearly all the single varieties. Thrips is a great plague here, owing in a great measure to the existence of some Thorn hedges, which harbour this pest; and the experience of the Messrs. Smith differs from that of Mr. Barnes and others, inasmuch as they find tobacco of very little use, but use a preparation something like Gishurst, which they say, as indeed I could see, effectually stops its ravages. There was also a quantity of their pretty rosy pink Azalea Clapham Beauty, which has, moreover, the advantage of being very early in bloom; and possessing as it does an excellent habit, it is a very desirable plant for the spring decoration of the greenhouse. Crispiflora rosea, an improvement on the old and pretty crispiflora, is also largely grown, and meets with a ready sale.

In the stoves I found a very excellent assortment both in old and young plants, of the rarer and more valuable plants that have been introduced of late years. Alocasia metallica, Lowii, and zebrina were excellently done; while Cyperus alternifolius variegatus was in greater masses than I have anywhere seen it. Here was also a good stock of the very pretty Saxifraga Fortunei, which will ere long find its way into many a cottage window, supplanting its plainer relative, which is now so extensively grown by cottagers.

In the cooler houses many of the recent introductions from Japan were found, such as Thujopsis dolabrata variegata, Retinosporas, Osmanthus, Eurya—plants which, if they only prove hardy, cannot fail in a few years to make a considerable change in the landscape gardening of our days. Many of the new varieties of Zonal Geraniums, which are more adapted for greenhouse culture than the open air, were also to be found here. Amongst them I noticed Marie L'Abbé, Mrs. Theirs, Ornement des Massifs, a curious plum-shaded scarlet.

Fuchsia Pillar of Gold, which was originated in this establishment, has proved itself a very useful ornamental plant, and when well grown, and mixed with others, the effect is excellent. There were large quantities of it grown here; but to my mind it looked better when placed amongst other plants than when used in large quantities. Cloth of Gold is another somewhat similar variety, which deserves all the praise that has been given to it, affording a very pretty contrast to the previous one. The other varieties of Fuchsias were also to be found here in large quantities.

In Balsams the Messrs. Smith are certainly in advance of all others, and I found pit after pit filled with plants which were maturing their seed. The different varieties are all kept perfectly distinct, and I can only say that I did not see one plant with single flowers throughout the thousands that were there; so that if single flowers are obtained from their seed it must be owing to some mismanagement in their culture; and as I had myself been disappointed, I asked Mr. Smith how it was that I came to have so many single flowers. He quietly asked me, "How do you grow them?" I told him that I potted them off singly, and then as the flower-buds showed rubbed these off, repotting them into larger-sized pots, and then trusting to the later buds for the bloom. "I thought so," was the rejoinder. "It is the earlier buds that ought to be depended on; and the plan is to leave them on and grow the plants well, so as to develop the flowers well." Some of these were very fine, quite like variegated Camellias, while those of a plum-coloured shade were truly magnificent.

It will thus be seen from this necessarily brief and hurried sketch, that in point of interest this nursery is not behind any of its metropolitan neighbours, and that enterprise, skill, and energy are at work to give it a foremost place. This Messrs. Smith have effected at a very large outlay; but the great sale that their productions have will, I doubt not,

amply remunerate them. I need hardly add that I feel sure that any one visiting this nursery, which lies conveniently between the Crystal Palace and Victoria line, and the London, Chatham, and Dover, will meet with the greatest civility, and be politely shown everything of interest pertaining to it.—D., Deal.

WINTER DECORATION OF THE FLOWER GARDEN.

I HAVE read with considerable interest the remarks of Mr. G. Abbey on the winter decoration of the flower garden. The subject deserves the attention both of the writers and readers of your journal. The present system of flower gardening renders it necessary that something should be done to remove the nakedness of the beds throughout the winter season. Geraniums, Calceolarias, &c., are gorgeous enough through the summer months; but by the middle or end of October, if not absolutely killed their beauty is entirely gone, and then the sooner they are taken away the better. But it would cause a very serious blank if the beds had to remain empty and bare from that time till the third or fourth week in May, the time when bedding plants would be again brought forth to occupy the place of their predecessors.

It becomes, therefore, a matter for serious consideration which way the deficiency would be best supplied. Of course the plants must be hardy to stand the rigours of the winter, but they should also be of an ornamental character. I know of nothing so suitable as evergreen shrubs, with their various shades of green and different habits of growth. I am not much in love with deciduous shrubs for the purpose, whether they be flowering or otherwise, as they look so bare when the leaves are fallen, nakedness being the object sought to be removed.

Your correspondent has given a list of those evergreens which are most suitable for decorating the beds when divested of their summer occupants, and any one taking that list or selecting from it will not go astray in the matter.

In reference to planting them, however, there may be a difference of opinion. I have been in the habit of following a plan different from the one recommended by Mr. Abbey, and one which some might feel disposed to adopt. If so, I think they will be satisfied with the result.

Your correspondent recommends that two-thirds of the beds be filled with shrubs, evergreen and deciduous, and one-third with bulbs and spring-flowering plants, and that each bed be devoted to one separate kind—grouping them, in fact. This is not my method. I prefer planting shrubs in every bed, but not to fill any of them, and to mix the different kinds together, carefully distributing each so as to secure variety and at the same time uniformity. The more conspicuous and distinct sorts are particularly attended to in this respect, Aucubas and Irish Yews, for instance; for wherever one of these is planted a similar one to match is placed, so as to balance, as it were, one side with the other. Yews should not be too numerous; one here and there to take off the flatness is quite sufficient.

The beds are 4 feet in width, the walks 2 feet. In small circular beds I place one plant in the centre. In the middle beds, which are nearly square, I place five—a centre, and one near each corner. The largest contain seven or eight, and the others about three each. When thus planted the garden presents a very striking appearance, exhibiting a great variety both of form and colour. Probably where there are large beds on grass, and these disconnected and far apart, the plan of your correspondent may be the best; but in geometric designs containing a number of comparatively small beds close together, I think it preferable to adopt the open plan above described.

Every bed is planted with clusters of the Crocus; and here again I follow the mixing system—not, however, with each cluster, which is of one distinct kind, but each bed contains clusters of each colour, yellow, blue, and white repeated all the way round near the edge at about a foot apart. Being planted near the edge they are out of the way of the bedding plants, and consequently are not disturbed when their flowering season is over. I find it necessary, however, to take them up every three or four years, for the double purpose of dividing them and planting them

at a greater depth, as they work up nearer to the surface every year by forming the young bulbs on the top of the old ones.

I should have planted a ring of Tulips or Hyacinths round inside the Crocuses; but these being beyond my reach, I have to make the best of the materials at hand, and the Crocuses on a sunny day in February present a picture which is not surpassed by Geraniums, &c., in the month of August.

The shrubs are not potted, but are removed in spring and autumn without the slightest injury, except the Portugal Laurels, which will not bear the constant removal, soon presenting a sickly appearance. All the others do well.—T. JONES, Manchester.

[We think that it is as well to print this without much comment. Edging beds with evergreens would also be a good idea, using Box, Ivy, Holly, &c., a foot high.]

THE ROYAL HORTICULTURAL SOCIETY'S CHRYSANTHEMUM SHOW,

NOV. 9TH, 10TH, AND 11TH.

THE opening-day was unfortunately chosen, being that on which those of high degree meet to celebrate the anniversary of the birth of England's hope and heir, and that, too, on which portly aldermen, good citizens, and many guests are wont to enjoy the splendid hospitalities of the Mansion House and City halls. There could, then, be no reasonable prospect of a large attendance of visitors, and a large attendance there certainly was not, the number present in the conservatory where the "show" was held never amounting at an outside computation to three score at any one time.

But what of the Show itself? There was but one exhibitor of specimen plants—Mr. Adam Forsyth, of Stoke Newington; there were but two collections of cut blooms, one furnished by the same exhibitor, the other by Messrs. Downie, Laird, and Laing, and there was but one collection of new varieties—that of Mr. Ingram, of the Royal Gardens, Frogmore. The unfortunate choice of an opening-day could have little, if anything, to do with the lack of competition, and this can only be accounted for by the inducement offered being certificates, bearing a money value, it is true, according to the receipts, but which in the present case must have been less valuable than American greenbacks. It is evident that without a more solid inducement than these certificates exhibitors will not come forward, and there will be no show; and, on the other hand, if there is nothing worthy of the name of a show, the public will not come if they become aware of that fact; or, what is more mischievous still, coming they go away angry and disgusted at having put themselves to much inconvenience, and wasted their time and money to meet with a disappointment. Among Mr. Forsyth's specimen plants which, however, had not generally arrived at their full perfection, there were good examples of Lord Ranelagh, orange red; Rifleman, ruby; Prince Albert, crimson; Bernard Palissé, a showy orange; Florence Mary, and some others. In Pompons we remarked nice standards of Cedo Nulli and the Golden and Lilac varieties of the same kind.

Of cut blooms, as already stated, there were only two exhibitions; that of twenty-four, from Mr. Forsyth, contained good blooms of Queen of England, Mrs. W. Holborn, Alfred Salter, Novelty, and other leading kinds; that of twelve from Messrs. Downie & Co. contained some blooms of remarkable size. Of the beautiful orange Jardin des Plantes there were blooms upwards of 4 inches across, while Lady St. Clair (white), was of even larger size. Of Alfred Salter there was an immense bloom, as well as large ones of Her Majesty, and Nil Desperandum.

Of Mr. Ingram's seedling Pompons Alice, a pretty free-flowering yellow, received a second-class certificate; and a similar award was made to Princess Beatrice, brownish red, the florets tipped and edged with yellow.

The only other feature in the Show worthy of remark was contributed by Mr. Veitch, of the Royal Exotic Nursery, being Cattleya labiata with five splendid spikes of its beautiful crimson lilac blooms, Lycaste Skinneri with eight fine spikes, and the interesting hybrid Cattleya Dominiana alba,

white, with the front of the lip purplish rose, and a delicate yellow tinge in the base.

It is due to Mr. Eyles to state that scanty as the materials were they were made to present the best possible appearance by the skill with which they were arranged. Chrysanthemums, plants of the Society's own, were placed by the sides of the main conservatory walk, whilst the baskets along the front were filled with Chrysanthemums and Geraniums, edged with Selaginella denticulata. Centaurea candidissima was introduced with good effect in some of the baskets. The eastern glazed entrance had likewise an interesting appearance, especially the further end, where a mixed bank of shrubs, Chrysanthemums, &c., served to shut out the view of the door.

This intended Exhibition, for Exhibition, except in a sense disgraceful to the Society, it was not, is only one of many—very many—evidences that the management is in totally incompetent hands. We will only quote at present one additional evidence.

Sir Joseph Paxton, as chairman of the Show Committee—a Committee appointed to inquire what alterations in the Society's Exhibitions are desirable—wrote an excellent letter, lithographed for circulation among the Fellows, asking for their opinions and information how they would co-operate in sustaining weekly shows. Replies were requested to be sent by the 15th of October, yet some of the Fellows only received a copy of the circular on the 8th of November, and some have never received any at all!

FLORAL COMMITTEE, NOVEMBER 8TH.—But few specimens for examination made their appearance this day. Had not Messrs. Ivory, Dorking, most kindly sent a large and most interesting collection of their multiformed British Ferns, which received a special certificate, there would have been a very small exhibition. Messrs. Ivory sent several new forms or varieties of British Ferns, among them Polystichum angulare grandiceps, P. angulare rotundatum, Athyrium Filix-femina Veronica, A. Filix-femina Victoriae, all of which received first-class certificates. Athyrium Filix-femina Barnesii, and A. Filix-femina tortile, with Scolopendrium vulgare marginato-papillosum—well may we ask "what's in a name?"—will be seen again before their merits are decided upon. Messrs. Waterer & Godfrey sent Cupressus Lawsoniana argentea, a very distinct glaucous-looking plant—first-class certificate.

Mr. Ingram, Frogmore Gardens, sent seedling Pompon Chrysanthemums, neither new in colour nor distinct from others in cultivation:—Princess Beatrice, a yellowish buff, not unlike Aurora borealis, but smaller, a nice compact flower—second-class certificate; Alice, an early, very small-flowering variety, deep yellow—second-class certificate; Gipsy Girl, yellow and buff; Pretty Polly, orange yellow petals, tipped with brown; Princess Alexandra, a small white; Little Bob; and Canary Bird, with bright lemon-coloured flowers like Berrol. From Messrs. Lee, Hammersmith, came a new species of Epidendrum (the name was missing) with dull purplish flowers, deep purple lip—first-class certificate; Epiphyllum truncatum tricolor, a very showy plant with bright scarlet flowers shaded with purple, and the backs of the petals having a bronzy tint—this is a great acquisition among the autumnal decorative plants—first-class certificate. From the same firm came also Epiphyllum truncatum Salmonium marginatum with crimson and white flowers.

Messrs. Downie, Laird, & Laing, sent twelve cut blooms of Chrysanthemum Queen of England, Jardin des Plantes, Lady St. Clair, and Striped Queen of England, three fine specimens of each—a special certificate was awarded them.

STOKE NEWINGTON CHRYSANTHEMUM SHOW.

The annual Exhibition of this Society took place on Thursday and Friday last, and was as great a success as the South Kensington one was a failure. Comparisons are said to be invidious, but no one who was at the Royal Horticultural Society's Show (we use the term for convenience) could help comparing what that Society, with all its high patronage, numerous supporters, and ancient prestige, then

effected, with what a few earnest amateurs accomplished without such powerful auxiliaries.

This year the Stoke Newington Show was held at the Tabernacle, Kingsland Road, instead of, as heretofore, at the Manor Rooms, and, being within a few yards of the railway station, was much more convenient of access. The display of specimen plants and cut blooms was even better than in former years, and not being scattered to fill space, was extremely effective. The arrangement was much the same as last year, the plants in pots being placed at the sides and ends of the room, whilst the cut blooms occupied the tabling in the centre, a row of pyramid Pompons running along the middle. It is not too much to say that there was not a bad specimen or bloom in the whole Show; a few might be defective, but they were amply compensated for by the excellence of the great majority.

For Six Plants Mr. Ward, Tottenham, was first, with Prince Albert, covered with its large crimson blooms, Golden Christine, Defiance, Annie Salter, Alma, and Lady Hardinge, all of which were large healthy plants, and in fine bloom. Mr. George, gardener to — Nicholson, Esq., Stamford Hill, came second with fine plants of Alma, Jewess, densely covered with its orange and red blooms, and very even as regards size, Little Harry, and Defiance. Mr. A. Forsyth, nurseryman, Stoke Newington, was third, with Vesta, Annie Salter, Lady Hardinge, fine, and others all good.

In the Class for Three Plants Mr. Howe, the Secretary, was first, with a magnificent specimen of Vesta 4 feet across, and with probably not less than one hundred fine blooms, Rifleman, and Lady Hardinge excellent. Mr. Forsyth was second—his Prince Albert was very fine; and Mr. George third.

In the Class for Six Pompons in eight-inch pots Mr. Ward was first. Salomon, Général Canrobert, and Duruflet, were remarkably fine, particularly the last, which was so densely set with bloom that there was not more than enough foliage left to set it off. Mr. Forsyth was second, having, among others, fine specimens of Cedo Nulli, Lilac Cedo Nulli, and Duruflet.

For Three pyramid Pompons, Mr. Butcher was first with nice plants of Cedo Nulli, Andromeda, and Général Canrobert; Mr. George second; and from Mr. Ward came Duruflet, Général Canrobert, and Cedo Nulli, in beautiful bloom, but they were not considered sufficiently pyramidal in their growth to entitle them to a prize.

Extra prizes were offered for the best two collections, and Mr. Howe carried off the first. His Prince Alfred had an extraordinary bloom, measuring 4½ inches in diameter every way, and in fact forming a perfect ball. White Globe, in the same collection, was 4 inches across, and beautifully incurved, while of Lord Ranelagh, Lady Hardinge, Antonelli, Annie Salter, and Alma, the specimens were likewise fine. Mr. Forsyth was second, with excellent specimens of Beverley, Chevalier Domanie, and others; and among Pompons, Golden Circle, and a very good standard Cedo Nulli.

The Cut Blooms formed an excellent and very effective display, and many of them were of extraordinary size and perfection. It would be tedious to enumerate the blooms exhibited in every stand, or even name the best where all were so good; we must, therefore, confine ourselves to stating that we observed a wonderfully fine bloom of Queen of England from Mr. Moxham, Lady St. Clair, White Globe, Lady Hardinge, Themis, Princess of Wales, varying considerably in colour but very beautiful, Prince Alfred, Jardin des Plantes, in some instances of astonishing size, Beverley, Nil Desperandum, and many others.

For Twenty-four Mr. Robinson, Islington, was first; Mr. Slade second; Mr. James third. Twelve, Mr. Moxham first; Mr. Ward third; the name of the winner of the second prize we omitted to take down. For Six, Mr. Moxham first; Mr. James second; and in another class for the same number, Mr. Howe first; and Mr. Butt second, the latter being first for a nice stand of Anemone-flowered varieties, and Mr. Snare second. Very good stands of thirty-six Anemone Pompons came from Mr. Ward and Mr. James, who took the first and second prizes respectively; and Mr. George had a first-class certificate for a seedling called Princess Dagmar, blush white with a high centre, which promises to be an acquisition. Several extra prizes were offered by members of the Society to winners in certain classes; three by Mr.

Salter for three blooms of Princess of Wales, and three for Robert James; three by Messrs. James & Howe for Robert James; and one by Mr. Snare for Jardin des Plantes. The last was taken by Mr. Cornwall, Kingsland, with some very fine blooms.

The exhibition, and the arrangements connected with it, reflected great credit on the Society and its Secretary, Mr. Howe, and we hope that it may continue to meet with that support which it so well deserves.

HEATING TWO PEACH-HOUSES.

I AM about heating two Peach-houses, standing upwards of 20 feet from a range of vineries which are about to be heated by hot-water. Of course I must take the flow and return pipes underground to the first Peach-house; but what I want to know is, How can I take a flow and return pipe to my second Peach-house without heating my first one? I have no sheds behind the houses, otherwise I would take them in that way. I intend forcing the first house, but only to assist No. 2 a little.—INQUIRER.

[We do not think it is possible to do what you propose—heat the second Peach-house without heating the first, except by having separate flow and return pipes for each. However, we see no necessity for this, as you mean to force the first house, and merely to assist the second. Let the flow and return go all the way; but join the flow and return in the first house by a semicircular joint, and shut off the circulation beyond by a valve or a stopcock. This will enable you to heat the first without heating the second. You will want more piping than this for the early house. When you do not want heat shut off from the other piping, and when you want heat in the second house without wanting it in the first, leave only the flow and the return, and counteract the little heat by more air. This will be every way better than taking a distinct flow and return to the second house under the ground. If you had given us the position of the houses we might have been able to advise better.]

GARDENER EMIGRATING TO NEW ZEALAND.

IN answer to the query of "J. C." as regards taking Strawberry plants to New Zealand, if some of our finer sorts could be taken they would, no doubt, be valuable, but good kinds can be had there. Tools should be taken, for almost everything in that way, clothing, and furniture, are from 50 to 75 per cent. dearer than in England. I have no doubt Quick would do well, as all our deciduous trees flourish there, and keep their leaves longer than in England. My friend took chestnuts, acorns, and the seeds of almost all our hardy trees; but said they were of little use, as there were plenty of all our common trees, as well as fruits and vegetables. He advises people to take a little of the seeds of the very best sorts of the following—Cabbage, Cauliflower, Peas, Radish, Cucumber (Melons will not do without a frame), Geraniums, Verbenas, Stocks, Asters, Delphiniums, and, in fact, the best of every kitchen vegetable and flower seed, as they will be handy; always, however, bear in mind that nearly all the trees, vegetables, and flowers which are grown in England are found there, being taken by former emigrants.

Geraniums, Verbenas, &c., will live out all the winter near a hedge where there is a little protection. Grass seeds may be grown there on a small scale, but it would be cheaper and better to take them. Were I going I would take all seeds that I might have saved, as well as all my friends could give me. My friend took chests of drawers, beds, blankets, carpets, linen, crockery, and all kinds of small articles, as these are dear there. Of course, this is only advice for married people; if single, take no furniture or household things. For the voyage take no hams or bacon, as pork and other good provisions in plenty are served out; but cheese, or anything that requires no cooking, is very handy. A few pounds of peppermint cakes or drops, or a few bottles of wine or spirits, a table-spoonful to be put into water when sickly, are very desirable. Also take plenty of Onions and preserves, as they are very good in sickness. Of course these instructions are for working people who

wish to save their money, as most luxuries can be bought on board by those who do not mind paying an increased price.—W. C.

LILIUM LANCIFOLIUM CULTURE.

It is not very generally known that the period at which *Lilium lancifolium* may be had in bloom, may be very greatly lengthened, and this simply by a system in the time at which different bulbs are to be started, the first quantity being by a very gentle system of forcing hastened into flower about the middle of July.

To effect this, carefully remove from the bulbs all decayed matter, old lifeless roots, &c., and set about potting them in the first week of January. Where pots of fine specimens are wanted choose 12-inch pots, giving them an efficient drainage. For soil use an admixture of good turf yellow loam partially decomposed. I prefer that in which an abundance of white sandy grit is found. This should be chopped up into moderate-sized lumps, to be afterwards sifted to remove all the more dusty portions of the soil. The more turf portions only ought to be used. With this mix a few lumps of charcoal, some well-decomposed leaf mould, adding a dash of silver sand. Fill the pots to within 3 inches of the top with these well mixed together, making the whole tolerably firm. Into this firmly press the bulbs, taking care not to bruise or otherwise injure the scales. Let the tips of the upper scales upon the bulb appear through the soil, placing the same firmly around them. This is very essential to all fresh-planted bulbs, &c. The number I generally place in a pot of the above size is from seven to nine. It depends whether any of them are likely to produce two stems upon the single bulb.

Any who may not wish to have large specimen pots, or may prefer to have them of a more portable size, cannot do better than choose seven-inch pots, in which four or five bulbs may be placed in a similar manner.

These smaller pots will not need half the care and attention that the larger ones do, as the same caution as to watering, &c., need not be observed. The large mass at this early season of the year getting so easily overladen with moisture, will cause the soil, being without roots, to sour if great care is not observed.

Place the pots in a situation where they will receive a moderate amount of light and heat; the temperature not to be below that generally kept up in a greenhouse. As I have before observed, care should be taken, especially at this early season, in watering them. They will require none until the plants have made a start, when a thorough good soaking of tepid water will greatly benefit these. They should now be removed into a temperature of at least 55°, with light and air. When they have made a growth of 6 or 7 inches they can be removed to the more airy end of the greenhouse, or to a pit, from which the frost is excluded.

At the base of that portion of the growth which may be above the soil, a quantity of strong healthy roots may be observed; firmly cover these with some pieces of turf yellow loam, leaf mould, &c., sufficient to fill up the pot to within the customary distance from the rim. With occasional sprinklings overhead, and as they advance in growth more liberal root-waterings, they may, taking care to tie them when necessary, remain in this situation until the period of their flowering, which should be about the middle of July at the latest.

The next batch may be potted about the middle, or in the end of February. These should be treated precisely like the former, save that they will require no heat, but should be placed in any sheltered position until they show signs of growth, when they should be removed into a light, airy situation, where the frost cannot reach them, there to remain until they require staking, and are showing for flower, which will be about the end of August.

The next in succession are to be grown entirely in the open ground, where they will flower readily with the following simple treatment. Pick carefully out of the old soil every bulb. I dibble these out in the ground where they are to stand, four or five in a patch, taking care to place them some 3 or 6 inches deep. An American-bed I find to be the most suitable for them, especially one of those which for the want of better material is composed of an ad-

mixture of heavy sandy loam. These small bulbs, some of them scarcely more than a scale in size, perfect a growth sufficient in one season to flower in the following one, and thus I have annually in that spot a goodly bunch of these blooming more or less efficiently according to the season, and giving a succession of flowers from July until the frosts of autumn visit us.

These Lilies have the additional merit of being good flowers for travelling long distances without losing either beauty or fragrance. They should be taken off the main stalk with a reasonable quantity of the flower-stalk, at from two to four days before the period at which they would naturally expand, and if desired to be sent any distance before expanding, they only require to be placed where they will not become crushed, wrapped up in paper. I forward them from here each season by post to beyond Inverness.—W. EARLEY, Digswell.

ENVILLE HALL.

(Concluded from page 376.)

We now pass from the museum to the comparatively open lawn, to which we have already referred, to notice the singular mass of Limes, one being of the *parvifolia* or *microphylla* kind, and the other the common Lime (*Tilia europaea*). Both kinds now come so close together as to resemble almost one mass. The *parvifolia* seems to have been three trees planted closely to each other, but now appearing as one, and sweeping the ground with their healthy branches. The common Lime had only been one tree, and though lofty, the bole is not particularly large; but branches from that tree had touched the ground, layered themselves naturally, in the manner of the Banyan tree, had a good fight for pre-eminence on the principle of the law of the strongest, and now good-sized trees are rising, with but very slender branch-like connections between the old stems and the new ones, and the process has been repeated, and even now the small outside branches that sweep the ground are many of them beginning to take hold of the soil. The circumference of the heads of these trees is respectively 132 and 116 yards. We are a little in doubt whether the latter figures are correct. A part of this fine mass of Limes is seen in the accompanying engraving.

Without attempting to describe the varieties of Hollies and other evergreens in these grounds, we must content ourselves with mentioning particularly three fine trees—the first is a beautiful upright-growing deciduous Cypress, near the mansion; the second a splendid Chestnut (24), near the east end of the seahorse pool; and the third is a very fine plant of *Picea nobilis*, well planted on a lawn between that pool and the museum walk. This massive plant, well worthy of an engraving, is 34 feet in height, 66 feet in circumference of branches, and 4 feet 10 inches in girth of stem. From opposite the fine Chestnut fine views are obtained over the pool, and across the rising ground of the park up to the arched gates, &c.

The seahorse pool (23) is one of those combinations of the seemingly natural and the purely artistic, conjoined with the mythological, that never fail to delight. The beauty of the statuary (the heads of which appear in the engraving) is enhanced by the softening influence of the mirror of water, reflecting the shading of the evergreens and the drooping Willows that fringe its banks. We have become so dull in all that pertains to classic lore that we were unable to read the history the figures were no doubt intended to illustrate, so we just make a story for ourselves, which may do until the true one is told. The central figure we conclude to be Triton, the son and the trumpeter of Neptune, blowing his shell horn to arouse the sleepy but beautiful Nereids to come and take their morning gallopade, that will leave no sound of hoof or footfall behind it. Striking as this pool is when in repose, what shall we say of it when a water jet rises to the height of 80 feet, when numerous jets play and cross each other, and when amid the mist and the spray the beautiful rainbows are ever forming and disappearing, now aloft, now almost touching the water, chasing each other as if some unseen fairyland, and not this earth, were their destined home?

If we go a little southward from this pool to a higher walk (25), we obtain one of the finest views within the

dressed part of the demesne. Looking down upon the pool we see part of the water, and most of the statuary, and onwards, past the fine Chestnut (24) on the left, and the mass of Limes on the right, part of the conservatory terminates the view in the engraving; but the eye sweeps far beyond that, and takes in the tower and the flagstaff of the parish church, &c. This view is that which we have engraved.

From this same walk (25) on the plan, a fine view is obtained over the top of the pool of the serpentine ribbon-border (30), which, commencing in a low level near the west end of the pool, winds somewhat abruptly up the hill, the rising as well as the winding giving additional charms to its beauty. Both these borders are beautifully backed by evergreens, which reflected the bright colouring of the ribbons. They were thus planted on each side of the walk beginning at the grass verge:—*Cerastium tomentosum*, 18 inches in width, followed by *Lobelia speciosa*, *Aurea*

floribunda Calceolaria, and old, bright, rather strong Scarlet Geraniums, each of these 18 inches in width, the same as the *Cerastium*. The dense planting, with the rise and bending of the borders, rendered them very attractive.

There is a beautiful Weeping Willow at the top of the seahorse pool; and between it and the terrace at the west end of Jordan's pool is a steep sloping bank of beautiful grass, the one pool being some 20 or 30 feet in height above the other. From the walk above this bank a fine view is obtained of part of the mansion over the head of the Willow, part of the seahorse pool, and onwards beyond the mansion, over part of the Scotch Firs, of the racecourse.

Jordan's pool (32), is much the largest, and has a brick wall all round its sides, and a nice boat-house. There is an island chiefly of the Alder, and some nice Oaks, Birches, and Willows fringing its banks. On the terrace at its west end are four very lofty vases filled with Scarlet Geraniums and sculptured with the heads of celebrated warriors, poets, and

statesmen; but which our artisans of the black country have christened The Twelve Apostles, showing that they knew rather more of their Bible than the great names of the world's antiquity. The great attraction of this pool is its wonderful jet, which rises in a straight column of water and spray to the enormous height of 180 feet. The boatman by rowing to the jet puts on ever so many devices; but to us one lofty jet was the grand one. Many years ago we witnessed the jet of the Emperor fountain at Chatsworth, and though memory is deceitful, and the present is apt to drive out the past, this at Enville seemed the more lofty and magnificent. One great charm was, that we were privileged with the sight of numerous beautiful rainbows, two or three in the dashing spray at one time. We had never seen any but the slightest appearance of them in similar circumstances before, but here they were massive, and no sooner was one gone than another and another appeared. We stood with our backs to the sun which was shining brightly. Mr. Craw said he never saw anything so grand in that way before. There might

have been some peculiar condition in the atmosphere that helped to give us so many of these shifting, shading, coloured bows. We could not help wishing that they had been seen by some four thousand of our brethren of the black country as something of the beautiful to talk about for days and years to come. The gardens are open during summer for two days in the week, and frequently there are from three to four thousand visitors, Lord Stamford adding to his other liberality, the great kindness of having these fountains played half an hour each day for their gratification.

These fountains are supplied from a reservoir on the elevated sheep-walks which we afterwards visited, and which is itself filled by two engines of thirty-five horse-power each, and managed by an engineer and assistants. The size of this reservoir, strongly and securely built, is in length 435 feet, width 135 feet, and depth 10 feet, and it holds when full 4,110,750 gallons. In noticing such works and their results, we could not help reflecting, that though it is often a great thing for the designer to derive personal satisfaction

from his work, it is still a far greater and nobler result to be thus the means of imparting a high-toned gratification to the thousands who otherwise might have little opportunity of being influenced by such assemblages of the beautiful.

By a walk on the north side of this Jordan's pool, we pass the boat-house (33), a rustic bridge (36), and continuing our course through a dell with picturesque wooded banks on each side, we reach the bird cottage in the woods. This charming retreat would just have suited some hermit and anchorite of the olden time, to try at least, however vainly, if happiness could be gained by shutting the heart up from the associations and the sympathies of humanity. The cottage is roughly piled with blocks of brick, covered with grey sheets of lead, and has even bits of stained glass in the windows, but is comfortably finished within to meet the wants of its inmates. Leaving out of consideration at present the workman and his family who inhabit this sequestered spot, its chief charm consists in the picturesque arrangement of the trees and shrubs, a fine Oak tree at the entrance, and great numbers of fantailed pigeons, which with their pure snowy plumage, contrasted charmingly with the dark sombre Yews, among which they moved as coquettishly, as if they had never known what it was to be disturbed by the presence of a stranger.

From this point we retraced our steps, and climbed up a steep bank to the pagoda (34), placed at the western point of the dressed grounds, with the rich woods behind it. A cluster of flower-beds had previously ornamented the front of this pagoda, but with great good taste these had been removed, so that nothing of the little, even though beautiful, should interfere with the open expanse of lawn, and its side masses of evergreens and single specimens of Conifers arranged for picturesque effect, or distract the attention from glancing over a good portion of the pleasure grounds, the racecourse beyond, and a portion of the country onwards to Dudley on the one hand, and the woodlands of Hagley Park on the other.

We forgot from what point through the woods we went to the sheep-walk, and the reservoirs for the fountains, but we could not help noticing that the fine picturesque effect of these boundary woods was chiefly owing to the undulating character of the grounds, and the high crests and the deep valleys between them. In one of these is placed the seat in the valley, with a wide expanse of turf between the shelving mounds, which were clothed near the edges with fine Oaks and other trees, with their branches sweeping the rich pasture. From this seat on which we rested a fine view is obtained of the surrounding scenery; and the same may be more truly said of the rich and varied scenery seen from the rotunda, which itself forms a fine feature in the landscape as approaching Envile from Stourton Castle.

But not to weary our readers, we may just state that the last place we visited in the park were the arched gates that led through to the drive to the upper sheep-walks. The view from thence was rich and varied. On the left the eye sweeps over Jordan's pool in the valley, the corner of the serpentine ribbon-border, and other fine parts of the flower gardens, passes on to the tower of Envile Church, and farther on to the great expanse of the common of Highgate Heath, and the black hills beyond. In the middle view the eye sweeps over part of the seahorse pool, a part of the front of the museum, with its fine oriel windows, the towers and domes of the conservatory, a portion of the village of Envile, and obtains peeps of the glass houses in the kitchen garden, whilst a little to the right part of the mansion is seen through the trees, the distant windmill, and farther distant still the Sedgley and Dudley hills. On the right the eye sweeps down on the mansion, with the temple pool in front (not shown in plan), fringed with Firs, Willows, and other trees, and in the distance are seen the sombre Fir woods of the racecourse—the view altogether is so striking, that the visitors to Envile should endeavour to realise it.

We must now conclude with a few general observations.

1. As to the industry, cultural skill, refined taste, and general intelligence of the superintendent of these gardens, were we to attempt anything in the way of eulogy it would be summed up in a single word "*Circumspect*"—Look around!

2. Few places owe more than Envile to the fine natural position, with its lofty undulating backgrounds. These

have been so improved by judicious planting, and leaving wide massive spaces for herbage, as to present a scene of rare contrasted beauty. Even in the more polished gardening departments, thanks to the good taste of the proprietors, and the various artists employed, none of these grand features have been obscured or frittered away by any of the so-called improvements of the day.

3. The style of flower-gardening adopted is one of the most simple and unique. There is no such thing as a regular group of beds, which, by the disparity of their size and the irregularity of their outline, are made to unite to form a symmetrical whole. The only form or figure of a bed used is that most pleasing of all, the circle. Each of these circles, as planted by Mr. Craw, with its centre and bordering, is perfect in itself. Where numbers of these are placed in masses, as south of the conservatory, and north of the ribbon-border, each circle is not only complete in itself, but it is planted so as to balance, contrast, or shade, with the circles near it, so that there is as much care taken in the planting as if the clumps belonged to a regular group. A look at the very reduced ground plan would lead the reader to suppose that these circles were crowded together so as to do away with the feeling of repose, but that is not so in reality, and this any one may perceive who will recollect that each of these usual-sized circles is from 18 to 20 feet in diameter, as then he will see that the spaces of lawn between them are wide. To compensate for even the appearance of crowding beds here, there are but few on the fine open lawns north and west of the conservatory; and perhaps the large circles there might be lessened in number with advantage. With all our love for the circle, however, and beautifully as these beds were filled, there seemed a degree of sameness even as to their outline, and the regularity with which they were placed upon the ground, so that, though we would not wish the present system to be altered, we would wish it to be so far broken in upon as to give variety even in outline. Suppose, for instance, that a simple regular group were placed on each side of the walk in front of the conservatory, not only would a new feature, as well as variety, be produced, but the clumps of the groups being placed closer together, there would be more of contrasted colour brought at once under the eye, and larger spaces of turf would be secured near the museum border, and round the fine purple Beech (13), whilst a good opening would be made for the introduction of vases and statuary, of which, considering their grandeur, these gardens cannot be said to be rich at present, if we except the seahorse pool.

4. The ribbon-borders are a grand feature at Envile, and that not so much owing to the planting and the plants, though both were very good, but to their massive backgrounds of various-tinted green of Laurels, Hollies, Laurus-nutus, and Rhododendrons. The fine spikes of the Holly-hocks looked very noble against such backgrounds. The very best level ribbon-borders we ever saw, as proofs of cultural skill and unremitting care, were at Oulton Park, under the management of Mr. Wills, but they lacked the grandeur of the post-office ribbon-border at Envile, because they had no such background.

5. In looking at the ground plan one would be apt to suppose that the walks would be too numerous, and that several, as yellow or brown strings could be seen from almost any place; neither is the case. We hardly recollect seeing one walk from another, except at the points of junction. The very number seemed necessary to get to see the different objects comfortably. The intrusion of the sight of other walks is almost constantly prevented by the undulating character of the ground, the position of the masses of shrubs, and even by the size and rounded outline of the beds.

6. Whilst the masses of shrubs and the background of the ribbon-borders are densely planted, all single specimens of Conifers and others will have ample space not only to grow, but to show off their beauties.

7. We have incidentally alluded to the kindness and liberality with which the noble proprietors of these grounds open them two days in the week during the summer to the public. Entrance is obtained by ticket, procured readily at the hotel or from Mr. Craw, the tickets being chiefly a matter of form, but so arranged as to enable the manager easily to know the number of visitors that are present each day. Thousands of all ranks and classes use and appreciate the

boon, and with scarcely an exception the great myriads act thoroughly as if they felt their sense of right and honour appealed to. We have lately heard a good deal of the axiom, that "Property has its duties as well as its rights." It is characteristic of our times, that so many of our nobles and gentry go far beyond the stern demands of duty in the sympathy they manifest for all that will interest, amuse, instruct, and elevate their humbler brethren. The standing aloof in solitary dignity, the attempt to live for ourselves alone, will ever be found a mistake and a failure, whether tried by the peer in his palace or the peasant in his cottage. We have heard some would-be independent people sing until they were hoarse—

"I care for nobody, no, not I,
And nobody cares for me."

But the louder they sang the more did they confirm the impression that they did care, just as the schoolboy who has learned enough to make him superstitious, "whistles the loudest to keep his courage up," whilst shaking like an Aspen leaf at every wind rustling among the grave-stones at night, as he passes through the churchyard. No man, however much he may wish it, can stand alone uninfluenced or uninfluencing, or escape if he would the attendant responsibility. A great step in human progress would be gained were there a more general practical recognition of the fact, that one of the very best means of securing happiness for ourselves, is simply to be engaged in making others happy.

And, lastly, whilst such means as these are presented for the gratification of the inhabitants of the surrounding districts, the best interests of the villagers of Envile have not been neglected. The last place we visited was a very elegant school-house, and residence for the schoolmaster, erected by Lady Stamford, and presented by her ladyship as a free gift to the village. Before seeing the master, we had a walk through the garden, and found that he was as fond of the garden as ourselves, although the hares had tried hard to lessen his enthusiasm by nipping the points of his favourite fruit trees. We hope that by this time they are thoroughly excluded by a close fence or wire netting. Everything in the school, from the stained and varnished open roof, the maps and illustrations on the walls, the tables and forms, and the unique desk of the master, spoke not only of comfort, but elegance, and in this respect contrasted strongly with what we had lately been reading of the dirty, hacked, and whittled appearance of the forms and tables, and even what served as tutors' desks, at Eton. We are not in a position to say what effect such appearances of the untidy and the dismal may have on the young gentlemen who congregate there, but we do know that a dirty church or chapel, and a miserable-looking schoolroom, exert a deteriorating influence on the rising generation amongst us of the working classes. At Envile we can fancy many an urchin curiously scrutinising the wonderful rostrum of the teacher, with its many distinct boxes, and next to countless drawers, all so bright with their varnished handles, until he feels that everything approaching the untidy and the slovenly would be quite out of place. We are not disposed, without a proviso as to the kind of beauty, to join thoroughly in the proposition, "A thing of beauty is a joy for ever," but we do maintain that all beauty does exert a softening, refining, and elevating influence. We hope the villagers will sufficiently appreciate their advantages, as that will be the best compensation they can give for such kindness and liberality.

We take this opportunity of correcting a misprint which occurred in the third paragraph of page 376, in which the first bed in the third row is said to be edged with Lord Stamford Verbena, instead of the Geranium of that name.
—R. F.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHEELING out manures, composts, earths, mud, &c., trenching, draining, making new walks, and repairing old ones, are amongst the principal operations at the present season in this department. Always make choice of suitable weather for performing each, with a view to cleanliness and good order. Asparagus, some of the earth may be removed from the surface of the beds, and its place supplied

with strong, rich, decomposed stable-manure, to which may be added, with good effect, a sprinkling of salt. The fine dry weather we have had lately has been particularly favourable for taking up Carrots, Parsnips, and Beet, and if not already done, let the ground they occupied be trenched; and where the soil is clay or strong loam, let it be ridged, that the frost and air may act on as large a surface of it as possible. If the ground is required for planting Potatoes, the ridges may be made 2 feet apart from the centre, and the Potatoes may be put 3 or 4 inches under the surface of the soil between the ridges, and the ridges will crumble down as frost approaches, and protect the tubers from its action. Jerusalem Artichokes, a bushel of them may now be taken up, and placed among some mould in any convenient corner, for use when frost renders it difficult to get them up in the open ground. The same applies to Horseradish. Onions, the ground intended for them next year to be trenched up, and some rich manure laid on the top, which must be well knocked about in dry frosty weather during winter. Peas, about the 20th of the month is by many considered quite soon enough to sow them, as also Broad Beans, to stand through the winter. Sea-kale, clear off the decayed leaves, and cover a portion with pots, to be ready for covering with leaves and fresh manure, or leaves alone if the other is not attainable. Ground may now be made ready for new plantations of this, Rhubarb, and Asparagus, and as these are what may be termed permanent crops, every care ought to be bestowed on the thorough preparation of the soil for them. The ground to be trenched $2\frac{1}{2}$ feet deep, manured, pulverised, and drained, and where it is exhausted in some of its essential qualities—as nearly all old garden soil is—there ought to be an addition of new loam; for real success this is imperative. Clear away dead leaves from all growing crops, and fill up blanks as they occur.

FRUIT GARDEN.

Continue to prepare for fruit-tree planting by draining, trenching, and pulverising the soil, and after planting stake, tie securely, and mulch them in good time. Clear away all dead leaves from wall trees, and remove the green fruit from Figs. The established strong-growing fruit trees that are tardy in producing fruit should be root-pruned; but this must be performed according to circumstances, if the trees are planted too deep, or the soil has been raised above or about them since planting, by all means fork the roots out carefully, and plant them again on the surface, spreading out the roots judiciously, and then mulch them. If the trees to be operated on are planted high and dry, fork about them at a reasonable distance, and prune back the main or strongest roots as you find them. Raspberry plantations to be cleared of the dead canes and superfluous wood, the suckers taken off, and, where required, the strongest to be at once planted for succession.

FLOWER GARDEN.

To keep the walks, lawn, flower-beds, and borders clear of the fast-falling leaves, when all traces of the labour and attention of one day may be effaced by the next, will now require unremitting attention, if the garden is daily visited for amusement and fresh air, or if it is seen from the windows. Now, that the frost has transformed the gay and lively tenants of the garden into blackened spectres, it is advisable to remove them out of sight, and to fill up their places with bulbs or evergreens, as recommended last week. We have seen small branches of evergreens stuck all over the beds as "make-believes" that they were plants in pots. The difference to the eye of taste is as great as the difference between mock turtle soup and real turtle soup to the taste of an alderman. Flower-borders of a stiff and unkindly nature will be improved by an admixture of road sand, leaf mould, wood ashes, or any other light soil dug in, leaving the surface to be fully exposed to frosts, when it will be in a more pulverised and fine state for planting or sowing at the proper season. Many trees and shrubs that had been at first planted to produce an immediate effect, are too generally left to spoil each other. The reluctance to prune and thin shrubberies is particularly conspicuous in the gardens of amateurs, but by removing such trees or shrubs as are too near, and by giving more space to the more valuable varieties a more natural and delightful effect would be produced.

GREENHOUSE AND CONSERVATORY.

The frosty nights will render a recourse to fires absolutely

necessary. Regularly remove all dead leaves and prevent the spread of moss in any situation. Creepers should be closely tied that they may interfere as little as possible with the fall of light on the houses. Give timely attention to providing a succession of bloom with which to keep the conservatory gay. Be careful not to let plants in bloom suffer for the want of water, giving weak clear manure water to Chrysanthemums, Salvias, Camellias, &c. Damp and mildew are the great enemies to be guarded against in the greenhouse, and these must be sharply looked after, especially in the case of plants that have not well ripened their growth, and are in rather a soft state. If such things as Geraniums, Cinerarias, and herbaceous Calceolarias must be wintered in the same house with Heaths and other hardwooded plants they should be kept as much as possible by themselves, as they will require a somewhat closer temperature than hardwooded plants.

PITS AND FRAMES.

Let straw shutters or whatever covering it may be intended to use here be prepared without delay. Expose the stock here freely to air on every favourable opportunity, so as to check growth and get the wood firm, in which state the plants will be less liable to suffer from the confinement which may soon be necessary than if kept close and coddled with too much warmth and moisture now. Very little water will be required at the root, but look over the stock every few days, withholding water until it is absolutely necessary, and then giving a moderate soaking, which is the only safe method of giving water at this season. If green fly makes its appearance on any of the softwooded things apply tobacco smoke at once.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

SEVERAL sharp frosts have made us look about us, as all our bedding stuff was in old pits and frames. However, as yet we have escaped unhurt.

Cauliflowers.—Took up some dozens of Cauliflower fit for use, and placed them in a shed, standing them upright, where we can throw a little dry litter over them if necessary. Took up a lot more, which would grow a little without detriment to their appearance, and planted them under the thatched shed in a part of the first Mushroom-bed that is now about over, and where also extra protection can be given if required; and moved a nice lot of young plants just beginning to show their heads, moving them with good balls, and planting them in an earth pit, to be covered with old sashes, and extra litter over that when necessary. The earth was very dry, but we merely watered round the balls after firming the soil about them, and left the surface dry, which will be a better preservative against frost than a moist state of the soil at the surface. The heads were also, by slanting the plants, well covered to their bottoms with the dry soil, which as well as the leaves would protect them. We have generally had a good supply from such late Cauliflowers so treated, if we can manage to keep mice from them in severe weather. Of course both rats and mice can easier penetrate into earth pits than those formed of brick, though they can also get into the latter when a light is left open for air. When, from severe weather, such crops must be covered up night and day for a week or two, it is a good plan to shut a cat in during part of a day, as it is very annoying on uncovering to find the best heads all nibbled. Where no such conveniences exist, but there is a good shed or back house from which frost may be excluded, and the Cauliflower-heads are nearly as large as they will be wanted, all the leaves may be removed, except the few short ones close to the head, and the stems cut over some 15 inches or so in length, and then fastened upright in damp sandy loam, just near enough for the heads to be free of each other. The heads thrown into sweet cold water for a few hours before using them will scarcely be distinguished from those cut from free-growing plants. For this plan the heads must be firm and wanting a little of their full growth, as if large they will open and spread out, and thus lose their compactness. Even in that case they make a nice dish when cut up into little pieces, and look like the little heads from white Sprouting Broccoli.

Looked over the *Cauliflower* plants in hand-lights. By some mistake we have too many. We wanted nine in a light, to be thinned in spring to four or five, but there are more we find, but they may as well stand now. These, as they have taken hold, we shall keep as hardy as possible until March, and will only cover the glasses after the plants have been frosted slightly. Potted a few of the forwardest plants left into 60-sized pots, to be kept protected during the winter, and shifted into larger pots as they grow. Pricked out a lot more of young plants in light, sandy soil, with a little sand on the top, so as to protect them with old sashes when necessary, as we find that in our cold place this is better than pricking-out by the side of a wall. These will be planted out finally about March, to succeed those under hand-lights.

Lettuces.—Took up a lot of the forwardest, and placed them in orchard-house, watering at the root as we went on, and leaving the dry soil as above on the surface. Hoed those that can be protected out of doors, and the younger ones intended to stand the winter, having great faith in a fresh-stirred surface for keeping frost in its severity from the roots.

Endive.—Covered up a part of a bed with dry tree leaves and a little litter, to prevent the leaves blowing about. Took up a lot of succession for orchard-house, and also for earth pits. Where none of these conveniences exist, a good plan is to tie up rather loosely, and then earth-up with dry earth, and place a board or a little litter on the top in severe or in very wet weather. Fine large green heads taken up now, with a little earth attached, will grow slowly and blanch at the same time, if packed rather closely in a dark cellar, or in any place where little light and no frost can reach them. These will keep good a long time, and eat very crisp and sweet. We have tried these, Cauliflowers, &c., in the dark passage of an old-fashioned ice-house, but though there was no fault with the look, the flavour was in general very insipid. So far as our opinion goes, everything suffers in flavour that has been long in an ice-house, or the chambers adjoining.

Chicory and Dandelion roots may now be taken up and stored ready to be used as salads when desired, by being forwarded in a dark place, or forced in a warm place, all the growth being made in the dark. To have these good, the heads should not be more than 6 inches in length, if an inch or two less they will be better still. When the leaves are drawn by heat to 9 or 12 inches in length, there is little more substance in them than thin paper. For a salad all these things look nice, but for flavour command us to a crisp Lettuce. We believe that Endive is often used, because it looks more ornamental in the salad bowl, but it lacks at the best of times the sweetness and the crispness of the Lettuce.

Mustard and Cress, where in regular demand, should now be sown once a-week. For small families nothing is better than shallow narrow wooden boxes—say 3 inches deep, and 3 or 4 inches wide. Small pots may also be conveniently used, just sowing a pot after the produce is cut over. Sandy leaf mould is about the best soil to grow it in, the surface made level, the seeds then sprinkled over it rather thickly, then patted level, well watered, and covered with a paper or cloth until the seed-leaves appear, when they must have light to make them green. It is not advisable to cover the seeds with sand or earth of any kind, as when thus covered there is a good deal of trouble in cleaning the crop. Done as above stated the crops may be cut clean over, and sent pretty well as cut to table.

Cabbages.—If the frost threaten to be severe, will take up or cut over heads well swelled of the common, and the Red not used; meantime have forked the ground among the young plants intended for the next spring's first supply. The grub now seems to let us alone. We think its leaving was helped by sprinkling a little tar between the rows.

Dwarf Kidney Beans.—Moved a number of pots, when the plants were in bloom and setting their pods, from a cold pit to where they could get some fire heat in a pit, as we want them in a fortnight. Even Scarlet Runners out of doors, though protected, are pretty well done for now.

Cucumbers.—Gave a little more heat to these, now bearing freely. Will hardly keep them over the winter as we used to do, as they are little in demand now, except on some

particular occasions, and they cannot be kept healthy without more heat than it has been deemed advisable to spend upon them. Did we mean to keep these plants on, we must not let above one fruit in three swell to its size. To do good and produce freely after Christmas, they must yield but sparingly now.

Mushrooms.—Covered the last little bit in the thatched open shed, as we want a lot shortly, and ere long our first bed in the Mushroom-house will be in. Put in more stuff for another bed. Our second piece in the shed is still producing freely. We find that the manure we are now using for a fresh bed is rather fresh and moist, but instead of waiting for it to dry, we mix a lot of road scrapings and road parings which are very dry with it, and it saves time and labour, and the spawn runs in the mixture beautifully. We have put a few tree leaves round our fresh spawn heap, as it was not spawning quick enough for us. We also damped the bricks a little, as we found they were rather dry. Whether in a spawn-brick or in a bed, the spawn runs most freely and healthily when the material is in a medium state, and neither wet nor dry.

Potatoes.—Looked over seed Potatoes and others. We have seen no appearance of the disease this season in the garden produce, though they were a very heavy crop. They were taken up early to put other crops in. This disease, however, is as puzzling to us as ever. In a field where, we were told, Potatoes were never grown before, where little, if any, manure was used, and where, owing to the drought, the crop was rather scanty and the specimens undersized, but quite sound when taken up, now they are going fast—hardly a tuber but is spotted when closely examined; and this is the case with late kinds, as Flukes and Regents, as well as with earlier kinds. At no great distance—say a mile—another field, in similar soil, and treated in much the same way, with the exception of being pretty fairly manured, produced a fair crop, and as yet no disease has appeared. We really begin to think that our wisdom has as yet done little in averting the disease, and that, in fact, philosophy knows but little as to what will bring it and what will keep it away.

Beet, Carrots, &c.—Took up those that were left, that the first, especially, may escape frost, and will pack up at the first opportunity, finding great lack of room for many of these purposes. A shed with strong rough benches is capital for all such purposes. We think we told how, for several seasons, the birds worried us with Beet, cutting off the seedlings as soon as they appeared. Those just taken up were transplanted, and, to beat the birds, we intend sowing under protection in future. Not a plant missed, and the size is liked better than when the roots are very large. We are told that very large thick roots are apt to have a hard core when boiled. These roots should be taken up with care, and the leaves taken off without cutting, as the colour is better when no wound is given to the root.

Celery.—To keep this all nice the siftings from our coal ashes have been spread over the beds, and a little stubble stuffed in among the plants, leaving the tops free, which will only be covered in the case of severe frost. For this purpose evergreen boughs are very good, and if very severe weather come a little litter may be placed over the boughs. This keeps the weight of the litter from the leaves of the Celery.

Ice in houses and heaps should now be used sparingly, and looked after carefully in all cases where water is scarce. Ice is more generally obtained for stores in November and December than in other months; but in this neighbourhood, had we ever such a severe frost, there would be no ice to be had, as we have no water to freeze. With so many wells becoming dry, a heavy continuous rain, or even snow, for a few days would be a great general blessing. The prevalence of scarletina and other fevers we believe to be much owing to the scarcity of water and its attendant evils.

FRUIT GARDEN.

Much the same as in last and previous weeks. Washed, cleaned, and painted the trees in the front of the Peach-house. Scraped off the surface soil for an inch in depth, forked up slightly, watered where dry, surfaced with a little cowdung, and then a slight covering of fresh dry earth, and then

crammed every available spot with bedding Geraniums, &c., in boxes. This gave us room in the earth pits for the Cauliflower, &c. Removed all the leaves and fruit in Figure-house, watered to prevent over-dryness, and fresh surfaced with a little soil. We will fill this house for the winter with bedding plants, &c. Before the frost became severe covered the Vine-border with about a foot of leaves, and a little litter over them. We should have liked them to be a little more moist, but we did not wish them to become cold, and a little litter will keep heat in, and thus the border be kept in a comfortable state to be started when desirable. We have more faith in this system than in throwing heat down into a border. Unfortunately our roots are all outside. This covering was especially necessary for the late house. Before covering we put the smallest surfacing of cowdung over the border, and on that a thin film of gas tar, as it is just possible we may yet have more water from the heavens than would be desirable for such a border.

Wood Covers.—A gentleman asked us if we considered gas tar a better plan than a good tarpaulin or wooden shutters, or frames of asphalt, for excluding extra wet and cold too; and we replied, "Decidedly not." "Why don't you have them, then?" Ay, why, indeed! Some amateurs, and the proprietors of small beautiful gardens, have an idea that the gardeners to ladies or gentlemen can just have what they like. A little practical experience in the generality of such gardens would soon tell them a different tale, and show them what makeshifts must be resorted to, in order that no extra bill may make its appearance. It matters not, though a proposed plan may be most economical, a great saving even in the end, it must not be more than dreamed about, if it involves an extra present outlay. Our own observation would lead us to say, that as a rule, there is more rigid economy, and more care taken to make the most of everything in gentlemen's gardens in general, than even in commercial establishments. The men who put their capital in such establishments, know the economy of having materials suitable for the destined purpose at once, instead of wasting their resources in doing, and ever doing, and never finished doing with makeshifts for the time. We once had a good deal to do with a carpenter, who as a regular Jack-of-all-trades, was a very clever fellow, and who partly from his own peculiar idiosyncrasy, and partly from the policy of the firm he long served faithfully, was in the habit of saying, as he finished every little job, "Oh! it will do for the present," and so it just did, for the present of to-day generally required a repeated *present* in a very short time afterwards. We allude to this more prominently just now, because of such an inquiry as the following—"I have received the following advice how to act from Mr. G., but then I perceive he does not follow out the plan he recommends. Just give me your opinion." Ah! were we poor gardeners like the lawyers, we would not so often be asked for our opinions. Were they paid for they might be deemed more valuable. However, in the case referred to, and in scores of others, the opinion and advice of our brother were quite correct, though he was not able to practise what in this case he preached. A man who is an enthusiast in self love, may err in recommending his own practice, but it is rare that an intelligent man will recommend a course different to that he himself follows, unless he has strong grounds and convictions of the superior suitability of what he thus recommends. For ourselves we have had many letters of thanks for recommending wooden shutters, covers, &c., for protection, and yet for many years we never have had one. That is no reason why in the end such covers are not superior to all others, as they undoubtedly are.

ORNAMENTAL DEPARTMENT.

Much the same as in previous weeks. We intended putting in more Calceolaria cuttings. As this season we are rather behind with extra work of various kinds it was fortunate we had a lot taken up and placed under cover, or we should have suffered, as those out of doors are too much injured. In the beginning of last week, the 7th inst., we had a lot of Calceolarias sent us—great plants taken out of the beds—and they seemed all right before we began to strip them off for cuttings, when we found every shoot so injured as to be of no use. They had been caught in the frost of Saturday and Sunday the 5th and 6th. We mention

this also for another purpose, and that is the next to uselessness of sending such large root plants to a distance. They will be valuable chiefly for the slips that could be taken from them, and these would have come more safely in small parcels in paper. We have also a lot of old Scarlet Geraniums by the sides of sheds, as well as inside; and as we cannot get at them yet we have covered them over with dry litter until we can do so; then we will strip and treat many of them as we did last season, making faggots of them in large pots or boxes, or placing them thickly in a cold pit when we can make room. Tree leaves will soon be down now.—R. F.

COVENT GARDEN MARKET.—NOVEMBER 12.

The supply both of fruit and vegetables is well kept up. Of the former, hothouse Grapes are in better demand; and the supply of Pines has improved. A few Dutch Peaches are still to be had. Walcheren Broccoli, Brussels Sprouts, Savoys, and other Greens are abundant and good; and of Potatoes large quantities have arrived both coastwise and by rail.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

GROWING FRUIT FOR SALE (Profit).—Our Covent Garden Market report gives the retail prices. It is quite impossible to forecast prices, they are so dependent on seasons and other contingencies which influence the supply. Call on Messrs. Webber, in Covent Garden, and ask Mr. Taylor to give you some hints. Hamilton's book on Pine culture was published by Mr. Masters, Aldersgate Street.

OAK LEAVES (An Irish Subscriber).—The numerous scale-like excrescences are a parasitical fungus; the white ball was crushed, but probably was a gall caused by the puncture of an insect, some species of Cynips.

PLANTING TERRACES (M. G.).—From your description we do not quite understand the position of the terraces. Neither of your figures is symmetrical as a whole. The repetition on the other side of walk will give more balance. The terrace on gravel and Box will look very well, but there will be a degree of sameness from having a white or light colour to all the beds, except 17. This, however, in some critics' estimation would be an advantage. We had some square gardens of Verbenas all edged with Cerastium, which looked very well, and will look well in winter. When tired of that arrangement, you might in another year edge 7 with white, 9 and 10 with purple, and 13 and 14 with blue, and the 17 might have a white edging. As to terrace garden—Does Golden Mint keep colour with you? With us it goes back, and so does the Golden Ground Ivy. In 9 and 10, we think you had better omit the Heliotropes, as they will not match with the Tropaeolum in habit; 17 and 18, Cloth of Gold; Heliotropes, purple, kept low; and Cerastium. We would, however, prefer dark Heliotropes for centre, and Cloth of Gold for edging; then 21 as now, 13 and 14, mix the Alyssum or Cerastium with a little Lobelia.

GREY VELVETY-LEAVED PLANT—TROPEOLUM ELEGANS CULTURE (E. G. H.).—The plant in Gnaphalium lanatum. It does well for edgings, and may be permitted to grow 18 inches in height or more, or be nipped to a few inches in height. It is not hardy, as most likely the recent frost will tell you. It is easily propagated by cuttings. Round large beds and, therefore, a sort of hedge, it will bloom and produce its rather sweet everlasting flowers. The Tropaeolum elegans is best kept on by cuttings, it should not have much less than 45° in winter to keep it healthy. It may be planted out the last week of May. To produce abundant bloom the soil should be poor, or vigour arrested by pulling off the strongest foliage. Tom Thumb Yellow and Tom Thumb Scarlet are yet as good as any. Fireball is brighter than Tom Thumb. In strong soil you must disleaf. By this simple process we can make any kind a mass of flowers.

INTERMEDIATE ORCHIDS FOR PLANT CASE (An Amateur).—You do not state the width of the case; but for one 7 feet long, 2 feet in height, and heated by tank beneath, we would choose the following:—Cypripedium insigne and venustum, Odontoglossum grande, Dendrobium speciosum and grande, Neottia plantaginina, Eletia hyacinthina, Oncidium leucochilum, at least for a commencement. From 50° at night would be ample for these if it suited your Ferns, with a rise of from 5° to 10° during the day. Less would do. But you can easily add or diminish by using a cloth cover at night for your case in severe weather, and putting hot water in your tanks the last thing at night.

PROTECTING A FIG TREE (An Old Subscriber).—The Fig having lost its leaves, unbind the branches from the wall, and tie them together, so as to be conveniently covered with straw. The large Figs may be removed, but the small ones must be carefully retained, and the branches, having been brought close together, should be tied with strong mat, and covered with straw to the thickness of about 6 inches, fastening it with tarred string tightly round the Fig-shoots, rather in front of them, and down to the root. This will be sufficient to protect them from the rigours of an ordinary winter. The straw should be taken off in May, covering the tree then with a mat or two on frosty nights, until well hardened. They should be fastened to the wall again by the time they begin to grow.

VINE PLANTING (Wm. Holland).—We consider the first half of March would be a very suitable time to plant a fresh Vine in an outside border. Prune the Vines of which the leaves are now falling by the middle of December, or about a fortnight after the leaves are all fallen. The Peach trees, to afford fruit in July, should be placed in the vineyry by the 1st of March. "The Vine Manual," price 2s. 6d., will be published this week, and it contains all that is necessary to know on Vine culture.

PRESERVING ACHIMENES ROOTS—WINTERING LILLIUMS (Elizabeth).—Keep them in the pots in a dry part of the greenhouse. If placed on the floor under the stage, free from drip from the plants above, they could not have a more suitable position. Lilium lancifolium may be wintered in a cold frame, plunged to the rim in coal ashes, with a slight protection of mats in very severe weather. The Amaryllis, we presume a greenhouse kind, should be kept in the pot in a dry, light, airy part of that structure, without any water until it begins to grow in spring. Lilium giganteum, also l. lancifolium, should not be allowed to become dust dry, but, nevertheless, be kept rather dry in the pots in any part of the greenhouse, except under stages and on flats. If the pots are on a damp floor they will need very little, if any, water during the winter.

VARIOUS SHRUBS (H. N. E.).—All the shrubs named require the protection of a cool greenhouse. They will not bear exposure, so far as we know, in any part of the kingdom, except in very favourable localities, as those from which you have them.

ALYSUM SAXATILE SEEDLINGS—VIRGINIAN STOCK TRANSPLANTING (A Subscriber).—The seedlings sown last June ought to bloom next April; but as they are small, and probably have not been pricked out, they very likely will not flower until the year following. The Virginian Stock may be transplanted to the beds now, taking care to remove and plant with a ball of earth to the roots. It must be done in mild weather, and is best deferred, if the soil be wet and heavy, until March. Lobelia speciosa is a half-hardy plant, requiring the protection of a cool greenhouse; it will not, therefore, live out of doors all the winter. The Roses in pots may remain out of doors, plunged to the rim in coal ashes, in a sheltered situation.

POTTING STRAWBERRIES FOR FORCING—CRINUMS NOT BLOOMING—DRYING FUCIASIAS (H. K.).—Strawberries for forcing ought to have been potted some months ago. The grand secret in growing Strawberries in pots is to have the plants well established before autumn, the pots full of roots, and the crowns plump and well ripened. As you mention potting now, we presume the plants are, as yet, in the open garden, and not in pots; if so, take up those with the most prominent crowns, and not more than a year, or at most two years old, by thrusting a trowel down on all sides about 3 inches from the centre, and pot such, with the ball entire, in seven-inch pots, using rich loam, and pressing the soil firmly around them. Water and place in a cold frame. If you have materials, as leaves, or litter, with which to make a bed about 2 feet thick, do it by all means, and half plunge the pots, but keep the lights off. This warmth to the roots will cause the plants to fill the pots with roots, and the heat being gone in a short time, if the lights are put on during frosty and wet weather, the plants will ripen their crowns; air, however, must be freely admitted when the weather is mild. In this case the plants, after being cleared of their bad leaves, may be placed on a shelf about 15 inches from the glass, in a cool vineyry, by the beginning of March. Failing the frame and materials to raise a little warmth, place the potted plants in a sunny sheltered situation, close to a south wall or fence, and have the shelf fixed forthwith, then place the Strawberries thereon, giving, until March, no more water than is sufficient to prevent the latter flagging, and air on all favourable occasions. Such plants very frequently give a fair crop, but not equal to those reared for the purpose. The Crinums may be induced to bloom by planting them in a sunnier and warmer situation in soil not liable to become wet during the winter. They do not bloom because the growths are not perfected. There is such a thing as a double Crinum, but it, with many of its predecessors, are not worth much. As for the Fuchsias, bloom them if you will up to Christmas, and then keep them dry, so as to afford a season of rest. If they are young plants they must be kept gently growing over the winter.

PROTECTING SHRUBS (A Very Old Subscriber).—The shrubs named would not be injured by any frosts we have had this season, the injury to the leaders being probably due to the recent removal. You may place a mat round them in severe weather, removing it in mild periods, but such protection is of little avail, and does quite as much harm as good.

SEED OF COMELIA (*W. R.*).—We do not know such a genus, nor a plant by that name.

VINES FROM EYES.—FIGS FOR BACK WALL OF VINYER (*A Constant Subscriber*).—Obtaining from eyes put in in February canes as thick as the little finger by autumn, is no difficult matter, and such are frequently produced. The eyes are inserted about half an inch deep, simply, in small pots of light, sandy, turf-like loam, slightly watered, and plunged in a bottom heat of from 85° to 90°, with a top heat of from 65° to 85°, and a moist atmosphere. The eyes soon start into growth, and, if kept near the glass, are not drawn up weak. To insure a sturdy and well-matured growth, a free circulation of air is kept up, care being taken to avoid cold draughts. When the pots are filled with roots, or rather when these present themselves at the sides, the young plants are potted in seven-inch pots, using turf soil of the same temperature as the house. This will be necessary in March or April. They are again plunged in a hotbed of 80° or 85°, and have a top heat of 65° by night, with a rise of 15° or 20° with sun and air, the latter being given at 75°, and taken off when the thermometer sinks to 80°. The vines are gently bedewed overhead through a fine syringe, night and morning, with soft water of the same temperature as the house. By June the vines will be strong, and need potting again. If it is desired to insure strong canes that will fruit in the following season, select the strongest, and have a 12 or 13-inch pot drained perfectly by a large crock over the hole or holes, a couple of inches of smaller crocks above it, and then 1 or 1½ inch of half-inch bones mixed with a little turf-like loam. Fill the pot with soil to the required depth for the vine, so that the latter may be placed an inch or two deeper than before, filling in round the ball with soil from turves a year old, and leaving half an inch for watering. Place in the hotbed, and train the cane near the glass, if possible about 1 foot from it, keeping up the same heat and moisture as before. Lateral will present themselves at every leaf; these should be allowed to grow, and the waterings being copious, and every alternate one liquid manure, the vines will grow at a rapid rate, and soon make a cane 20 feet long. This not being desired, stop them at 8, 9, or 10 feet, according to their strength, and this will cause the cane to thicken, the laterals being stopped at the sixth leaf. More laterals will take their rise from the stopped laterals, but the cane will now be beginning to assume a russet hue. The quantity of water is now to be lessened, more air given, and the laterals by degrees brought nearer the stem, until they are finally removed by the time the wood becomes brown and hard. They are then cut clean away, in order to admit as much light as possible to the wood, in order to ripen it effectually, and the house is kept dry, and no water given, except to prevent the leaves falling prematurely. By this plan, we have canes as thick as a walking-stick, and have fruit on them in the following April—six or eight bunches of about a pound weight on each. Our "Vine Manual" contains directions for raising vines from eyes to fruit the following season. The Brown Turkey is the best of figs, and that you seem to have under the synonyme of Lee's Perpetual. "Brown's Perpetual" is probably the Brown Turkey. Rich dressings of manure (cow dung is best), or watering with manure water, will enable you to improve their size. The Singleton, or White Ischia, is a good fig, but a bad bearer.

ASPARAGUS-BED MAKING (*M. D., Pontefract*).—Drain the ground effectually to a depth of 4 feet. Make the bed now by digging out the soil 6 feet wide for a bed 4 feet wide, and 3 feet deep; place a layer of dung 3 inches thick at the bottom, which may be partially decomposed stable manure, and then a layer of soil; fork this up and thoroughly mix it with the dung beneath, and then place another layer of dung and soil upon it, forking as before, and so on, until the bed is brought to the level of the surrounding ground; then put on a layer of dung with an additional 3 inches of leaf mould, if you have it, and 6 inches of soil over that. Fork over the bed, so as to mix the dung, leaf mould, and soil together, and leave rather rough, so that the frost may do its work during the winter. In March fork over the bed again, and in the last week in that month, or first of April, plant three rows of giant, two-year-old plants, at 1 foot apart.

GUANO WATER FOR EVERGREENS (*A Constant Reader*).—Weak guano water will not injure the shrubs named if it be applied when they are growing and stand in need of water, but it should only be given at that time. It will do no good at other times, though it may not prove injurious. The application of it to geraniums successfully does not imply that it may be given to all plants indiscriminately.

WALL FRUIT TREES FOR THE MIDLAND COUNTIES (*T. S.*).—You will have room for ten trees, which should be, Pears—Marie Louise, Louise Bourne of Jersey, Winter Nellis, and Beurré de Rance. Cherries—May Duke, Elton, and Florence. Plums—Green Gage, Purple Gage, and Coe's Golden Drop.

PLANTS AND VINES UNDER ONE ROOF (*A. Z.*).—A detail of your experience will be very acceptable. Your queries shall be answered next week.

INSECT ON FERN (*J. S.*).—The insect on your Dicksonia antarctica is the common brown scale. Dip the plant into a strong solution of starch, let it dry on, and remain for a week, and then wash off by syringing.

SEAWEED FOR NEW ASPARAGUS-BEDS (*A Five-years Subscriber*).—We have used seaweed with great success, not only in making asparagus-beds, but as a mulching during winter, removing it in March. Your mode of making the beds is good; and, as you have little manure to spare for the purpose, a foot thick of fresh seaweed will not be too much, mixing it with the soil equally from top to bottom, but keeping the noted manure nearer the surface, still mixing it well with the soil to at least a depth of 18 inches. You may bring the soil at the bottom of the trench to the top, which is what we presume you mean by bringing the loam to the surface, providing it is not heavy. The crowns of the plants should be covered with 2 or 3 inches of soil at the time of planting. Your one-year-old plants are good, but they will be longer before they come into bearing than if two or three-year-old plants were employed; but the certainty of growth will be increased, and the produce better, by planting young plants rather than those a year or two older.

NAMES OF FRUIT (*J. P., A Young Gardener and Subscriber*).—Your Apples and Pears were named in our Number of November 1st, page 360, under the initials, *J. P.* (*J. C. Wheeler*).—1. Beurré Claireau; 2. Uvedale's St. Germain; 4, a cross with the Siberian Crab, very pretty; 5, Pyrus trilobata. (*Anxious Inquirer*).—2, Fondante d'Automne; 3, Glou Morceau. (*Charles Ellis*).—Your Apple is Court-Pendu-Plat. There is no work on Apple-gathering, but you will find such instruction in all good gardening books. (*Albert*).—1, Bishop's Thumb; 3, Autumn Pearmain; 4, Parry's Pearmain; 5, Franklin's Golden Pippin. Numbers omitted were not recognised. (*Old Subscriber*).—1, Passe Colmar; 2, Gansel's Bergamot. (*P. Lang*).—

Your Pears are—1, Croft Castle; 2, Crasanne; 3, Belle de Nôl; 4, Crasanne d'Hiver; 6, Vicar of Winkfield; 7, Ne Plus Meuris; 8, Spanish Bon Chrétien; 9, Bellissime d'Hiver; 10, Verulam. (*G. Wadhurst*).—Pears.—1, Vicar of Winkfield; 2, Beurré Diel; 3, Easter Beurré; 4, Glou Morceau; 5, Beurré de Rance; 6, Beurré Diel. Apples.—2, Beauty of Kent; 3, Lamb Abbey Pearmain; 4, Winter Greening; 5, Hawthornden. (*Japonica*).—Pears.—1, Gendesheim; 3, Fondante d'Automne. Apples.—1, Wormsley Pippin; 3, Reinette Dorée; 4, Adams' Pearmain; 5, Court-Pendu-Plat; 6, Winter Greening; 8, Dumelow's Seedling; 11, Dutch Mignonne; 12, Hawthornden. (*J. L.*).—1, Dutch Mignonne; 2, Marmalade Pippin; 3, Loan's Pearmain. (*B. D.*).—2, Count of Wick; 3, Pomme Violette; 4, Hawthornden; 5, Royal Pearmain. (*E. S.*).—2, Napoén; 3, Beurré de Rance.

NAMES OF PLANTS (*F. W. Steaford*).—Your Fern is Cyrtomium falcatum. (*A. L. B.*).—Your Ferns are—1 and 2, Pteris tremula; 3, Phlebodium aureum. (*Filicites*).—1, Lastrea Filix-mas; 2, Athyrium Filix-femina; 3, Lastrea dilatata; 4, Nephrodium mole; 5 and 7, Asplenium ebenum; 6, Cystopteris fragilis. These are, probably, the correct names, but no one can be certain from such scraps of fronds. (*A. McKelvie*).—A capital cristate form of Cystopteris fragilis, somewhat approaching to regia. (*M. D.*).—We are still of opinion that your plant is Salvia Grahamii. It certainly is the plant known by that name in gardens, and, as far as we can see, only differs from the wild specimens, with which we have again compared it, in being more robust in habit; but that is no more than might be expected in a garden plant, particularly in one upon which the hybridiser has been at work. Are you quite sure that the plant you formerly had was correctly named? (*Annie*).—1, Bupleurum fruticosum; 2, Ruscus aculeatus. (*J. H.*).—Tabernæmontana coronaria. (*S. A.*).—Probably *A. monanthemum*, but perhaps one of the allied Mexican species, as *leptophyllum*. There is not enough to decide by. The other is *Campyloneuron decurrens*. (*A. Ten-months Subscriber*).—Phlebodium aureum. (*W. R.*).—1, Nephrolepis tuberosa; 2, Anemia flexuosa.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BRAHMA POOTRAS.

It is said there are people who honestly disbelieve that Napoleon Buonaparte ever existed; who think Waterloo a sort of historical fiction. On the other hand, it is said people repeat falsehoods till they believe them true. It is said George IV. related a charge at Waterloo till he fairly believed he commanded and led it in person. It is hard to know how to describe or to classify this hallucination. It may exist with the strictest veracity, and the persons may be satisfied they are telling truth, while they are, in sober earnest, guilty of that which to every one else is a palpable falsehood, without any foundation whatever.

There are others who will not believe a thing after it has proved itself. The result may be plain as the sun at noon; but it will not be believed, or it will be tortured and twisted till it looks or sounds difficulty. Henry V. of France, as some call him, the Duke de Bordeaux as others call him, had a public reception at Frohsdorf for those of his faithful nobles who chose to undertake the pilgrimage from France to that place. We should imagine the old marquises and the "preux chevaliers," dating in unbroken line from the Crusades, the real "sang azur" for generations; grand old fellows—we do not believe many young ones went—but rather fussy, and sticklers for etiquette. The dear Prince lived as usual, a full allowance of meals, and very little walking. When he was at table the pilgrims were allowed to circulate through the apartment. When he walked they followed, and admired him at a distance. Fancy a party of four, all wearing the cross of St. Louis, all mounting the white cockade: gentlemen to the backbone—two old, two middle-aged. It is known the Prince is somewhat lame, and, though painstaking conceals it at times, at others it is very perceptible. Fancy him walking along a gravel path forty yards ahead of the four pilgrims. Every now and then, when the plan of the gardens permitted it, they cut across or ran round in order to be able to see him nearer, and probably to be recognised. On one of these occasions, after he had passed, the two fine, tall, old men stood watching him. All at once there was an exclamation from one of them. "Ah!" he cried, "our dear Prince has one leg shorter than the other." "Shame," said his companion; "it is impossible—our Prince cannot be lame." "But see, he limps." "Yes," shouted the other, "that is because one leg is longer than the other, not shorter!" "But you must see—" "No I won't see, and I can't see; he may have a longer leg, he cannot have a shorter!" and the two old friends parted in dudgeon.

Very ridiculous, is it not? Well, then, how about the Brahmases? In entering on the question we address ourselves to two classes. We will tell "W. H. B." that which we believe to be true, and have tried. When we have done

that, we fancy the infidels "in re Brahmans" will be "handsomely whipped," and "knocked into a cocked hat."

Manufactured breeds are good only for a time, and require to be constantly replenished from the original stock. Let the breeders of the beautiful Sebright Bantams speak. How long will their pets retain the perfect comb, the faultless tail, the accurate lacing? All the points will disappear one by one, and, after three or four seasons, the lovely little bird will be a common black and yellow-blotted bird, with sickle tail, and very likely a cup comb. It is notorious to all breeders that cross breeds (and manufactured birds are nothing else), not only cannot be depended upon, but they throw back, and every now and then produce an apparently pure bird of a very different breed from their own. While this is a proof of mixed parentage, if a breed will go on for years reproducing itself without even an occasional sport, it affords good evidence of purity and distinctness.

Things are now tolerably well settled in the poultry world. Some do not know the difficulties there were in its early days, and others have forgotten them. Cochin-Chinas were the first celebrated fowls; they came with double combs; five claws were common; they had unmistakable Dorking heads, and every now and then they appeared with good showy tails. Our best judges were not deceived by these things, and they soon, by setting their faces against improper mating, got the classes filled with pure birds. No one, in those days, ever dreamed the Cochin-Chinas were not a pure breed. They have remained pure to this day, and will do so. They began the "mania;" and when it was a little on the wane the Brahmans appeared. Some of those who had done well by dealing in Cochins, and who were far-seeing men, were wishing to realise, and seeing that the elevation of a new favourite would of necessity lessen the attraction and value of the old, they tried, by every means in their power, to depreciate the poor Brahmans. First it was declared they were no breed at all, and then they were pronounced to be an offshoot of the Cochin. We will premise that we have bred thousands of Brahmans, and have hundreds now, all true to a feather, all pea-combed, all pencilled alike, and all feathered on the legs. In twelve years we have never bred a clean-legged chicken.

Probably, says one, Cochin crossed with Malay. This would bring no pencilling. Instead of fluff it would give scanty feathering. It would give long clean legs, brown plumage, and a hard, warty, skinny face, for the easy comfortable well-to-do look of a Cochin pullet. In the cooks, the Malay in every point is the antipodes of the Cochin; he is long, gaunt, and angular, and no mixture however skilful can, with these materials, make a Brahma.

The next among the incredulous say Cochin and Dorking we should say this is far more likely than the previous cross, but it will not make the bird. It would give clean and white legs, five claws, and drooping single combs. It would give ample tails.

The Grey Chittagong has far more affinity to the Malay than to the Brahma.

We do not envy the feelings of the Barnum class of the American community, who think it smart to prove they have done the world by selling pure things on their warranty, and declaring them to be impure and worthless as soon as they have received the money for them.

It seems to us the difficulty of proving the purity and distinctness of breed in Brahmans becomes less every year. For a long period they had to inhabit the various class. They have emerged from it, and at late Shows they have been among the most numerous classes, in some instances second only to Dorkings. What do they show? No collection of oddities, but a class fine in colour, comb, and marking as any Hamburg. No sign or remnant of Malay, Chittagong, or Dorking. The evidence of those who keep them is everywhere the same. They differ from Cochins in the following particulars—they eat less, they lay more, they are harder, they are better mothers, and they are more disposed to seek for and to find their food. All this is patent, and yet like our old Marquises, the opponents of these birds, shut their eyes to plain truth, and simply say, "It is impossible these fowls can be pure."—B.

[Our witty and able correspondent, who should have been the Attorney-General of Brahma-Postra, had Gulliver discovered that kingdom, having undertaken to maintain that

the Brahmans are a pure breed, like a skilful advocate ridicules the contrary opinion, ignores the evidence sustaining it, and puts forward only that which shows that there are some shades of difference between a Brahma and others admitted as Cochins. He passes by the fact, that Dr. Bennett, the originator of the Brahmans, declined to reveal their origin. He passes by the fact, that Mr. Burnham states, from the evidence of his own senses, and Dr. Bennett has never contradicted the statement, that they are a cross between the Cochin and Chittagong. But, says our correspondent, they have pea-combs. We reply by asking, Is this any more a proof of a distinct breed than is the rose-comb in a Dorking? And we next ask, Is their breeding true to colour any more a proof of a distinct breed than White, Buff, and Brown Cochin-Chinas being true to their colours? Let it be admitted that Brahmans are hardier, eat less, lay more eggs, are better mothers, &c., than Cochin-Chinas, and what then? Our correspondent will not for a moment argue that these qualities establish a distinct breed. The dark-coloured varieties of Cochin-Chinas vary nearly similarly from the White variety. We have always thought and still think the Brahma resembles the Cochin-China in all the essentials on which a distinct breed can be founded. Let it be admitted to be a variety in feather—and that it is a good variety we do not dispute.]

BIRMINGHAM SHOW.

We have pleasure in stating that the entries for all departments of the forthcoming Exhibition in Bingley Hall are most satisfactory, and that the building will, as usual, be well filled with objects of varied interest. As we remarked in drawing attention to the arrangements for this year, there is ample evidence that the Birmingham Show is firmly established in public favour, and that the efforts of its promoters are thoroughly appreciated by all whose co-operation it is desirable to obtain. No other society has hitherto founded an exhibition so diversified in character as that at Birmingham, bringing together as it does so much that is attractive to the agriculturist, the poultry-keeper, and to many who are enabled to engage in horticultural pursuits; and the experience of the last few years is sufficient to prove that nothing will be overlooked which is calculated to give increased value to these pleasant and useful meetings. We subjoin a statement of the entries for this and the four preceding years:—

	1860.	1861.	1862.	1863.	1864.
Cattle	110	104	131	163	151
Sheep	42	66	110	92	104
Pigs	75	72	70	93	91

—(*Midland Counties Herald.*)

A SOUTHERN POULTRY SHOW—MERITS OF COCHIN-CHINA FOWLS.

In your valuable Number this week you have published a letter from "A WILTSHIRE RECTOR" strongly advocating a poultry show for the South of England, in which desire we southern poultry-rearers heartily concur. Birmingham is too distant, and Brighton and other small Shows do not give any prizes to make it worth our while to send our best birds. I think, however, that your correspondent has either not had sufficient experience of the different sorts of fowls most useful for table and laying purposes, or else his fancy leads him too strongly in one direction, or he would not so strongly urge the claims of the Dorking fowls as so superior to all others for the table.

They are, no doubt, very good when they have passed the perils of chickenhood, and are well fattened for several months; but they are more delicate to rear, more subject to disease than either Cochin, Spanish, Polish, or Crèvecœur, and do not come to perfection for several months. The Cochin is extremely hardy, roup is unknown amongst them, and at

three months old they are perfection for the table. I will allow that the breastbone is rather too prominent; but this does not prevent there being a much deeper and larger slice on the breast than there would be on any Dorking chicken of the same age, however fatted.

I have had many Cochins, hatched since July, killed this month for table; they weigh from $5\frac{1}{2}$ to $6\frac{1}{2}$ lbs. the pair of pullets. These have not been cooped, but fed in open poultry-houses, and the flesh is more white, juicy, and delicious than that of any fowls I have ever known of other breeds. After six months old they require to hang a day or two longer; but a six-months cockerel, well fed, is quite perfect for table, and as large as a small Turkey. They fatten more readily than any other fowl, from being of so tame and quiet a disposition. If taught to come to call, and never driven, they allow themselves to be touched and stroked by those with whom they are acquainted.

I have had Dorking and Cochin chickens in the same clutch treated exactly alike, and the difference in growth has been very remarkable. The Hamburgs have their merits, no doubt, but such wandering birds are a great difficulty to all poultry keepers. The eggs are lost; they mix with the other birds, for no fence, wire, or distance will teach them bounds; and as for table, you might as well expect to fatten a Black Spanish fowl as a Hamburg. I think many people are in the dark as to the superior eatable qualities of the Cochin fowls, from there being such numbers of cross-bred, long-legged, long-necked, narrow-chested birds so called, which bear as much resemblance to the high-bred Cochin as a Mulatto does to an Englishman; but against a real pure-bred the Dorking would stand no chance in competition for the table.

I hope, if we have a Southern Show, that we may have a class for Crèves Coeurs, which, as far as I can judge, having only kept them a few months, bid fair to rival some of our best breeds as egg-producers and birds for the table.—COCHIN.

GLoucestershire Ornithological Society's Show.

THE third annual Exhibition of Canaries and British and Foreign Cage Birds was held at the Lecture Hall of the Working Man's Institute, Gloucester, on the 8th, 9th, and 10th inst. The entries were very numerous, nearly a thousand birds being shown. The competition in Norwich Canaries, between Messrs. Mackley and Walter, was very close. The Lizards were splendid; the Belgians were perfection; and the Mules very fine, the first and second-prize birds being first-rate.

BELGIANS (Clear Yellow).—First, G. Corbett, jun., Birmingham. Second, J. Mayo, Gloucester. Very Highly Commended, W. Rose, Birmingham; G. Corbett, jun. Highly Commended, J. Mayo; W. Phillips, Old Basford, near Nottingham. Commended, G. Harding, Ashton-under-Lyne; W. Williams, Nottingham; W. Townsend, Gloucester.

BELGIANS (Clear Buff).—First and Second, G. Corbett, jun., Birmingham. Very Highly Commended, J. Mayo, Gloucester; J. W. Price, Derby. Highly Commended, G. Harding, Ashton-under-Lyne; J. Brown, Birmingham. Commended, J. Brown.

BELGIANS (Any other variety of Yellow, Buff, or Variegated).—First, W. Phillips, Old Basford, near Nottingham. Second, G. Harding, Ashton-under-Lyne. Very Highly Commended and Commended, G. Corbett, jun., Birmingham. Commended, J. F. Hadland, Gloucester.

NORWICH (Clear Yellow).—First, R. Mackley, Norwich. Second, W. Walter, Winchester. Very Highly Commended, R. Mackley; J. W. Price, Derby; W. Williams, Nottingham. Highly Commended, W. Walter; G. Moore, Northampton. Commended, S. Brown, Birmingham.

NORWICH (Clear Buff).—First, R. Mackley, Norwich. Second, W. Walter, Winchester. Very Highly Commended, W. Walter; R. Mackley; W. Williams, Nottingham. Highly Commended, H. Sawkins, Gloucester; J. W. Price, Derby. Commended, H. Sawkins.

NORWICH (Variegated Yellow or Buff).—First, W. Walter, Winchester. Second, H. Sawkins, Gloucester. Very Highly Commended, G. E. N. Rawlinson, Gloucester; H. Sawkins; W. Gamble, Northampton. Highly Commended, H. Sawkins. Commended, R. Mackley.

NORWICH (Any other variety of Yellow or Buff Variegated).—First and Second, H. Sawkins, Gloucester. Very Highly Commended, J. F. Hadland, Gloucester.

LIZARD (Golden-spangled).—First, J. W. Price, Derby. Second, B. Pointing, Old Basford. Very Highly Commended, J. Lingard, Ashton-under-Lyne. Highly Commended, Rev. A. Johnson, Horsleydown, London. Commended, G. Harding, Ashton-under-Lyne; J. W. Price.

LIZARD (Silver spangled).—First, W. Williams, Nottingham. Second, Rev. A. Johnson, London. Very Highly Commended, G. Harding, Ashton-under-Lyne; W. Williams; B. Pointing, Old Basford.

JONQUE CINNAMON (Not Belgian or Norwich).—Prize, J. F. Hadland, Gloucester. Commended, H. Sawkins, Gloucester.

MEALY CINNAMON (Not Belgian or Norwich).—First, J. Knibb, Northamton. Second, H. Sawkins, Gloucester. Commended, J. Wynn, Northamton.

BELGIAN (Clear Yellow Half-bred).—First, J. Mayo, Gloucester. Second, G. Clapham, Upton St. Leonards.

BELGIAN (Half-bred, Any other colour).—First, E. Dallimore, Gloucester. Second, H. Sawkins, Gloucester. Highly Commended, W. Walter, Winchester.

PLAIN YELLOW-CRESTED (Not Belgian or Norwich).—First, G. Harding, Ashton-under-Lyne. Second, W. Walter, Winchester. Very Highly Commended and Highly Commended, S. Brown, Birmingham.

PLAIN (Yellow Crested).—First, G. Clapham, Upton St. Leonards. Second, J. Bowler, Horsepools, near Gloucester. Commended, W. Walter, Winchester.

PLAIN BUFF.—First, J. F. Hadland, Gloucester. Second, W. Elison, Gloucester. Commended, W. Walter, Winchester.

PLAIN YELLOW OR BUFF VARIEGATED.—First, W. Walter, Winchester. Second, Very Highly Commended, and Commended, J. Mayo, Gloucester. Highly Commended, W. Perris, Gloucester.

JONQUE GOLDFINCH MULE.—First, G. Crocker, Plymouth. Second, R. Mackley, Norwich. Very Highly Commended, H. Sawkins, Gloucester; W. Walter, Winchester; R. Mackley; G. Crocker. Highly Commended, W. Walter; G. Crocker.

MEALY GOLDFINCH MULE.—First, J. W. Price, Derby. Second, W. L. Clapham, Northampton. Very Highly Commended, W. Phillips, Old Basford. Highly Commended, H. Sawkins, Gloucester. Commended, W. Walter, Winchester.

ANY OTHER VARIETY OF MULE OR HYBRID.—First, J. Lingard, Ashton-under-Lyne. Very Highly Commended, W. Walter, Winchester.

BULLFINCH.—First and Second, Miss Waring, Gloucester.

GOLDFINCH.—Prize and Very Highly Commended, J. Mayo, Gloucester.

LINNET.—Prize, W. Walter, Winchester.

SKYLARK.—Prize, W. Walter, Winchester. Very Highly Commended, J. Mayo, Gloucester.

BLACKBIRD.—First, E. Welfare, Highnam, near Gloucester. Second, J. F. Roberts, Gloucester. Very Highly Commended, C. Rose, Gloucester.

SONG THRUSH.—Prize, G. Cambridge, Gloucester. Commended, C. Forty, Gloucester.

LARGE BRITISH BIRD.—Prize, H. Arkell, Gloucester. Very Highly Commended, W. Gainer, Gloucester.

GRASS PARROQUETS.—Prize, Mrs. L. Fouracre, Gloucester.

ANY OTHER VARIETY OF SMALL FOREIGN BIRDS.—Prize, W. Walter, Winchester.

GRAY PARROT.—Prize, W. Bennett, Gloucester.

ANY OTHER VARIETY OF LARGE FOREIGN BIRD.—Prize, Very Highly Commended, and Highly Commended, Miss L. Fouracre, Gloucester.

BEST COLLECTION OF CANARIES IN ONE CAGE.—Prize, J. Mayo, Gloucester. Very Highly Commended, H. Sawkins, Gloucester; W. Walter, Winchester.

BEST CASE OF STUFFED BIRDS.—Prize, —Skelton, Cheltenham. Very Highly Commended, B. Holt, Gloucester; J. James, Gloucester. Highly Commended, J. Mountaney, Gloucester.

The Judges were Mr. G. J. Barnesby, Derby; and Mr. O. Nicholson, Fareham, Hants.

COLLINGHAM POULTRY SHOW.

THE ninth annual exhibition of the above Society was held on the 3rd inst. The entries this year were far in advance of former occasions, both in quality and numbers.

Spanish were good. Dorkings contained some excellent pens. A first-rate pen of old Whites stood first in the Cochin class, Buffs second, and Whites third. The Game classes were splendid throughout, especially the first-prize pen of Duckwings, which were immediately claimed, and will doubtless very soon repay their fortunate purchaser. Mr. Swift's Brown Reds, Miss Crawford's Whites, and Sir St. G. Gore's Duckwings deserve especial mention. Spangled Hamburgs were but poor, except the winning pens. Pencilled, however, made ample amends, both classes being capital; Mr. Power's Golden and Sir St. G. Gore's Silvers well deserve their honours. The latter appear to clear all before them, and we never remember seeing so good a pen. Bantams formed also excellent classes. In Game we preferred many pens before the first-prize—the Rev. S. Reynolds Hole's Blacks. The second-prize Whites were first-rate.

Rouen Ducks were few in numbers, but better specimens it is difficult to meet with. Mr. Boyle's first-prize Islington birds gaining the same distinction here, Mr. Lang taking second, and the Worcester winners being highly commended. Mr. Smith's Aylesburys, which were also very good, obtained the first prize in the Variety class.

Game Bantam Cocks were a large class, the winner, a beautiful Black Red, fully deserving his position.

We are pleased to announce that the prize list has been greatly increased for another year by an addition of classes and increased prizes.

The Pigeons formed an excellent array. Carriers were

numerous and good. Mr. Oates's Short-faced birds were first-rate, as also were his justly-celebrated White Trumpeters. Messrs. Sanday, Edge, Yardley, and Jessop well deserved the honours they obtained.

Exhibitors are greatly indebted to the Committee for their excellent arrangements, and unwearied attention and courtesy. The following is the list of awards:—

SPANISH.—First, E. Brown, Sheffield. Second, W. Cannan, Bradford. Third, R. W. Boyle, Dublin. Highly Commended, W. Massey, Gedney, Commanded, M. Brown, Melton Mowbray.

DORKINGS (Any colour).—First, Sir St. G. Gore, Wirksworth. Second and Third, J. Smith, Breeders Hills. Highly Commended, Sir St. G. Gore, Commanded, H. Savile, Rufford Abbey.

COCHIN-CHINA (Any colour).—First, J. Stalev, Collingham (White). Second, R. Swift, Southwell (Buff). Third, T. W. Zurhorst, Belle-Ville, Dublin (White). Highly Commended, M. Brown.

GAME (Black-breasted and other Reds).—First, G. Wolstenholme, Sheffield. Second, R. Swift, Southwell. Third, J. W. Pope, Biggleswade. Highly Commended, Sir St. G. Gore; J. Doncaster. Commanded, Sir St. G. Gore; J. Dyson, Halifax; W. Ilingworth, Sturton, Retford.

GAME (Duckwings and other Greys and Blues).—First, J. Carless, Hoveringham. Second, Sir St. G. Gore. Third, J. Smith. Commanded, J. Bradwell; J. Doncaster.

GAME (White and Pile, or Any other variety).—First and Second, Miss E. Crawford, Farnsfield. Third, C. Spencer, Thurlston. Commanded, C. Spencer.

HAMBURGES (Golden-spangled).—First, Sir St. G. Gore. Second, Messrs. Birth & Bolter.

HAMBURGES (Silver-spangled).—First, Sir St. G. Gore. Second, W. E. Brierley. Commanded, Sir St. G. Gore.

HAMBURGES (Golden-pencilled).—First, J. E. Powers, Biggleswade. Second, J. Garris, Bradford. Highly Commended, A. Nuttal, New Church, Manchester.

HAMBURGES (Silver-pencilled).—First, Sir St. G. Gore. Second, J. Holland, Worcester. Highly Commended, A. B. & T. Kenyon, Accrington; R. Roy, Worcester; T. J. Saltmarsh.

BANTAMS (Gold and Silver-laced).—First, R. Swift. Second, T. C. Harrison.

BANTAMS (Game).—First, R. Dodge. Second, Miss E. Crawford. Highly Commended, Hon. J. W. Fitzwilliam; R. Toder; Sir St. G. Gore; R. Dodge; R. Swift.

BANTAMS (Black, White, or Any other variety).—First, Rev. S. R. Hole. Second, Sir St. G. Gore. Commanded, D. Causer, Erdington; H. Savile; J. Stalev.

DUCKS (Rouen).—First, R. W. Boyle. Second, S. Lang. Highly Commended, Sir St. G. Gore. Commanded, Miss E. Crawford.

DUCKS (Any other variety).—First, J. Smith. Second, Sir St. G. Gore. Highly Commended, J. R. Jessop; H. Savile; J. Smith; M. Brown.

BARN-DOOR FOWLS.—First, R. Cooper, Collingham. Second, Mrs. Hitchin, Besthorpe. Third, H. Mantel.

GAME BANTAMS.—**Cock.**—First, Miss E. Crawford. Second, G. Smith. Highly Commended, W. C. Brierley; R. Dodge; C. Aukland; E. Brown.

PIGEONS.

CARRIERS.—First and Second, G. H. Sanday, Holme Pierrepont. Commanded, G. H. Sanday; H. Yardley, Birmingham.

POWTERS.—Prize, E. Brown.

MOTTLES.—First, W. H. C. Oates, Besthorpe. Second, H. Yardley.

BALDS OR BEARDS.—First, W. H. C. Oates. Second, J. W. Edge, Aston New Town.

SHORT-FACED TUMBLERS (Any other variety).—Prize, Mrs. Oates.

BARS.—First, H. Yardley. Second, W. Massey. Highly Commended, G. H. Sanday. Commanded, J. Firth.

JACOBINS.—First, G. H. Sanday. Second, W. Massey. Commanded, G. W. Edge.

OWLS.—First, G. H. Sanday. Second, H. Yardley.

TRUMPETERS.—First, Second, and Highly Commended, W. H. C. Oates.

TURBITS.—First, J. R. Jessop. Second, H. Yardley.

FANTAILS.—First, J. Hives. Second, J. W. Edge. Highly Commended, D. Causer.

ANY OTHER VARIETY.—First, M. Ord. Second and Third, H. Yardley. Fourth, J. W. Edge.

JUDGES: Poultry.—T. Challoner, Esq., Brunt Leys. *Pigeons.*—W. B. Tegetmeier, Esq., Muswell Hill, London.

SOUTHERN COUNTIES SHOWS.

YOUR correspondent, "BRAHMA POOTER," asks for any suggestions from me, as to the possibility of getting more southern shows than there are at present. Although not pointedly writing on this subject in my remarks in the same week's Journal, I hinted at one of our great difficulties, the want of a large population who would make the show day their holiday, and I am disposed to think it important to insure success in a financial sense, that the poultry, should be attached to cattle shows. I have at various times visited shows, purely of poultry, and have been forced to reflect thus: "Well, if the visitors are not more numerous than they are at present, this can never pay," and I have seen these shows cease after a second or third annual exhibition. It appears to me that amongst the general public, a poultry show is not sufficient to obtain the holiday for the working men. "What do you want with cocks and hens?" is, perhaps, the reply to the request; but if it is the annual

meeting of the "Agricultural Society," the response can hardly be negative, and I think all allow that when poultry are shown, it is the department most thronged. Well, then, if I am correct in this idea, it would appear to be the first duty of exhibitors resident in the neighbourhood of an agricultural association, to urge the tacking on poultry, and if this has been already done, to try to improve the prize list. Here let me say, that in two instances where I have tried this course, it has been very successful, and the Secretaries have been most courteous, although personally unknown to me, in considering any suggestions I have offered, and often in trying them.

Well, then, let me suppose that some brother or sister maniac has been successful so far in inducing the agricultural society to admit our pets, the show, as regards poultry, may be a perfect failure, simply because the Secretary does not understand the importance of advertising, or if he advertises at all, he does it insufficiently. It has frequently happened to me to read reports of shows in your Journal, to which I would have sent specimens willingly, but your notice of the show is the first notice I have seen of it; in fact, the show is over when you first hear of it. Or, again, the advertisement appears for the first time on the day the entries close. How would a diminished scale for shows, when inserted three times, answer? This, however, is beyond my tether.

The Secretary might secure a tolerable entry, by cutting from the catalogues of the larger shows the names of exhibitors residing within a certain distance, and sending them at once a schedule and certificates of entry by post, soliciting entries.

I am not so certain that according to the locality selected for the show, an increase of certain classes of fowl, will do much for southern shows. Manifestly, this will not make the entries greater, if exhibitors do not know that such a show is about to be held. This latter point is very essential, especially in the lesser shows, as held in the north. Their proposed existence must be made known. I should say it was simply owing to this fact, that no Brahmans were seen at Tunbridge Wells. Give them but a chance, and they may be seen. Dorkings may be a southern county bird, but they are kept all over the country, and have numberless admirers, now that by experience their delicacy during chickenhood appears to have been overcome. Hamburghs, on the contrary, certainly have more friends in the north.

Are there no friends to poultry who have influence with the Gloucester Agricultural Association? Time was, when they used to have a splendid show of poultry in connection with the animal portion, but some years ago it was discontinued, and thus an annual show was lost to the south. I hope some person may have sufficient influence to restore us this.

One word in conclusion, as to the Poultry Club, the short report of the meeting noticed in your pages, lately contained a statement which will go far to disarm much of the opposition, at least, so I humbly imagine; the alteration of name from "Rules for Judging," to "Standard of Excellence, &c., for exhibition," is very important. The exposition given by good judges, the reasons why they have in certain cases awarded prizes apparently against the standard would be useful to all of us, and your own columns proved very lately that the best general Judge of the day, Mr. Hewitt, has no objection to defend his judgment in certain cases. I should myself have been greatly pleased with an explanation of awards in another class, it is, however, too late now.—Y. B. A. Z.

WINTER AND SPRING MANAGEMENT OF STOCKS IN COMMON HIVES.

I BEGAN bee-keeping this season, and have five straw hives in a shed (same as Neighbour's). They stand on cases with drawers for feeding, on Nutt's principle, and are all well covered-up with coats and carpet. Now, as ventilating hives in winter is recommended, I want to know if I should remove the carpet, &c., and open the block fronts in the cases on which the hives stand, and insert, over the holes, into the feeding-drawer or cases perforated tin, and then ventilate the shed well in which the hives are? My main object next

year will be to get swarms so as to start a lot of frame-hives or boxes.

Please also say if it is wise in the spring to disturb the bees to clean the floor-boards, and when is it the right time. I have partly closed the entrances to my hives by means of wedges. Do you consider this wise, as it stops ventilation? About a month ago my hives weighed from 20 to 30 lbs. each, and they seem strong. About what time should you resort to feeding, as I want early swarms?—J. A.

[Common straw hives require no ventilation, and the less they are meddled with during winter the better. If the coats, carpets, &c., have been long in their places, take advantage of the first fine mild day to remove them, and clear out all vermin, such as spiders, moths, earwigs, &c. After shaking and beating (the coverings, not the hives), replace them and make all snug for the winter. The latter end of February or early in March, according to the season, repeat the operation, and if you can with little disturbance substitute clean floor-boards for the dirty ones, so much the better. A few ounces of food given at regular intervals by means of an inverted bottle, two or three days apart at this season, will be of use in stimulating the breeding powers of the queens. Entrances should be contracted during winter, but even this must in some degree be regulated by circumstances, a populous colony requiring more air, and, therefore, a larger doorway than a weak one.]

HOW TO RECTIFY IRREGULARLY-BUILT COMBS.

I FIND the following passage in a recent letter from one of my most valued apianist correspondents.

"Some of the writers in THE JOURNAL OF HORTICULTURE complain of their combs on bars being crooked, and fixed transversely.

"If you found a Woodbury frame-hive in this condition, and wished to inspect the middle combs, but found it impossible to move the frames, how would you proceed to make the inspection? Would you begin by taking out the side bars first, and polish each bar straight in succession? or would you begin at the place where you wish to make the inspection, and pull up the frames, *nolens volens*, having first inserted a knife between the bars, so as to separate the combs?

"I make a supposition with the view to an answer in the Journal for the benefit of novices."

In the case supposed by my correspondent, I should commence by extracting a side comb (that which happened to be the straightest, for choice), and rectify whatever irregularity might exist in each comb one by one, partially or even entirely detaching from their bars such combs as might require it, and after straightening them, temporarily support those which had been either partially or wholly detached by means of wire, &c. All these temporary supports may usually be removed the next day; but it may not be amiss to state that all operations of this kind must now be deferred till spring is pretty far advanced (say April), and should on no account be attempted either late in autumn, or during winter.—A DEVONSHIRE BEE-KEEPER.

VARIATION IN LIGURIAN BEES.

WILL you give me your opinion upon the enclosed specimens of bees? No. 1 is from a hive which breeds all alike, with the exception that about one in a hundred is darker than the rest. No. 2 is from the hive referred to in page 342 of THE JOURNAL OF HORTICULTURE, and which breeds all varieties. No. 3 breeds all alike; but all are darker than the original stock, unless the few in No. 2, which are most brilliantly marked.

I should esteem it a favour if you would let me know whether any are pure or not, and whether, as I am told, pure-breeding queens can be obtained from the egg of a hybridised one, if impregnated with an Italian drone, or if, when they are once impure, they remain so.—A. N. B.

[The colour fades so much in dead Ligurians, that the specimens accompanying your letter are really of little use

in helping us to decide the question submitted to us. Nevertheless, you are welcome to our opinion as far as it goes. No. 1 we should consider pure, as there is some degree of variation even in the purest stocks, and the only test we admit in our own apiary is an entire absence of common bees. This rule condemns No. 2 as hybridised, and would clear No. 3 from suspicion, if (which we rather doubt), the bees are really "all alike." We see no reason why an isolated black stain should not in the course of time be bred out of Ligurians, if you can but avoid a relapse, just in the same way as the Ligurian strain becomes bred out of the common bee in a few generations. The difficulty would be in avoiding a repetition of the dark taint.]

JOINING LIGURIAN QUEENS AND BEES TO ENGLISH OR BLACK BEES.

In uniting queens there is always a risk, and I cannot find out the mystery why the bees will not accept a queen that is given to them, and after they reject her, if she is given to another stock they receive her joyfully. Again: the same stock that rejected the first queen will gladly accept another queen, if given to them almost immediately afterwards. A short time since I had a case that illustrates the point.

Having imported direct several of the most pure, beautiful, fertile Ligurian queens to be found on the continent, I placed one over a stock for some hours that had its queen removed two days before. I then admitted one bee at a time and they behaved very well, until half a dozen had been admitted, when they seized and attacked the queen, and I could not separate them without taking the queen up in my fingers and actually pulling the bees from her. This took place four times, when seeing that the bees would not accept her, I put her over another stock, and when I admitted the bees they received her joyfully.

I then gave the stock that had rejected the queen another of the imported Ligurian queens, and they received her in a friendly way and conducted her in triumph into the hive.

Since I sent you the account of joining bees on the 14th of October, I have joined five more lots of bees, and everyone successfully. They were driven on the 31st of October, but I do not recommend driving bees so late in the season, but the farmer had neglected them, and would not feed them. The bees in some of the stocks would not leave the combs, so we had to cut the combs out and brush the bees with a feather into the empty hive. I did not hastily discard peppermint scent until I found it from practice useless.—WILLIAM CARE, Clayton Bridge Apiary.

OUR LETTER. BOX.

COCHIN-CHINA FOWLS (E. C.).—We imagine your birds are Silver Cinnamons—the body a sort of French creamy white, and the hackle darker. They will breed good chickens with a buff cock, and are an esteemed variety. Another class is ordinary Cinnamon, and is coloured exactly like the spice after which it is named.

MOULTING OF SPANISH PULLETS (Cochin).—We have known them when hatched in January to change their feathers the same autumn almost entirely, but not regularly to moult. The cocks do, and we have some now naked-necked.

BEST-PAYING FOWLS (One who Wishes to Make his Hens Pay).—Buff or Partridge-coloured Cochin Pullets, and an adult Dorking cock, will supply eggs in the winter, and produce good table chickens. The Pullets should be bought every year, and their predecessors parted with.

FOOD FOR SKYLARKS (G. R. B.).—Bread and cheese is a first-class food for Skylarks. A little whole hempseed, groats, or cooked meat finely minced may be added occasionally with benefit. Larks should always have a green turf to peck at, and the bottom of the cage be thickly covered with clean dry sand for them to dust in. Hempseed is best given whole, but is not a necessity, and must be used sparingly. The meat must not be salted.

GERMAN PASTE (Idem).—Take two table-spoonfuls of lard free from salt, beat it in a saucepan till it is nearly boiling, add four table-spoonfuls of treacle, keeping the saucepan near the fire but not putting it on again, and stirring the treacle well in gradually. Keeping it still near the fire just to keep warm, stir in peasmeal till it becomes a stiff crumbly mass; a little mawshead to be added. About $\frac{3}{2}$ pints of peasmeal go to the above quantity.—B. P. B.

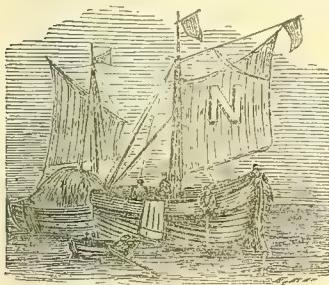

SQUIRRELS IN CONFINEMENT.—In your impression of the 25th of October, your correspondent, Mr. Hunter, states that Squirrels neither jumped nor ate acorns. This, I think, is unusual, as I have long kept some of these pretty animals, and I have now two, who daily spring and leap, and freely eat acorns, which, indeed are their principal meal. They live in a cage with some wild Rabbits, several varieties of Doves, and a pair of Golden Pheasants.—GEORGE H. BROOKS.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 47.3°, and its night temperature 33.7°. The greatest heat was 60° on the 28th, 1828; and the lowest cold, 9°, on the 23rd, 1858. The greatest fall of rain was 1.21 in.

AUCUBA JAPONICA VARIEGATA BEARING BERRIES.

One who had the pleasure of seeing the plant will have forgotten the interesting and handsome specimen of *Aucuba japonica vera*, covered with its brilliant scarlet berries, which was exhibited by Mr. Standish, of Ascot, at the first spring meeting held at South Kensington on the 9th of March last.

Few plants, if any, ever received such unanimous and well-merited approbation. It has been the only new plant of the year which has been signalised by having the Society's Silver Flora Medal awarded to it. For this addition to our ornamental shrubs we have to thank Mr. Fortune, who introduced it into this country with many other very valuable Japanese plants.

At the time when this fruit-bearing Aucuba, it being a female plant, was introduced, the stamen-bearing or male plant was brought with it, by the fertilising powers of which we were promised in due time to be able to make the well-known *Aucuba japonica variegata*, which is a female, a fruit or berry-bearing plant. The promise then made has been fully realised; and a fine plant of our old friend *Aucuba japonica variegata*, 8 or 10 feet in circumference, can now be seen in Mr. Standish's nursery at Ascot, well covered with berries, which though at present green, are fast showing symptoms of the approaching change to bright scarlet. The plant which is now producing its berries, was temporarily planted in one of the Vine-houses for the purpose of being experimented upon. It is truly most interesting and gratifying to all true lovers of horticulture to see the perfect success attending the fertilisation of this plant.

The time is not far distant when the male or pollen-bearing plant of this shrub will be attainable by all; but at present few only possess it, the value being so great and the stock very limited. In the meantime we may anticipate the privilege of seeing these shrubs, which grow so luxuriantly in every situation in this country, and which are so ornamental by their variegated foliage, covered at Christmas (a rival with our truly-loved English Holly) with brilliant scarlet berries.

There are many other varieties of the Aucuba, not yet sufficiently abundant to be known, but very beautiful and varied both in foliage and in the berry. Mr. Standish has a plant now ripening its berries, which appear to be of a bright yellow colour. There is very little doubt but that next year many varieties of Aucuba will be exhibited. Several of the leading nurserymen have been making collections; and when these new kinds are acclimatised, and within the reach of the public as respects

their price, a very great addition will be made to the hardy evergreens now used for winter-garden decoration in this country.—X.

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 4.

ONE great point in a tour is the sort of talk you meet with during its course. On the coach or in the steamer you are thrown into much nearer relationship with your fellow passengers than on the less sociable railway. Unhappy they who wrap themselves up in their dignity and chew the cud of their own thoughts, instead of enjoying a healthy interchange with the minds of others!

My black tourist's bag with its conspicuously visible trowel was a useful help to me in the matter. It proved a sufficient introduction to foreigners, and to those pleasant English people who travel with the happy wish of being pleased with God's glorious creation, whether in the human or natural world. Many a treasure has found its way to my bag from a fellow traveller's wallet, unlocked by the sight of the magic trowel. Many a talk has it given me of the vast forests of America, many a comparison of their vegetation with our own.

Shall I be pardoned if I say that of all foreigners I prefer Americans to travel with? Their keenness and comprehensiveness of sight is extraordinary. While another would but take in the general outline of a view, an American has perceived and jotted down tidily in his memory every important feature, each tiny peculiarity. I once spoke to one of the scarcity of Ferns about Loch Lomond. "Yes, madam," he replied; "but I gathered thirty different wild flowers there in half an hour."

Americans talk to you at once, and talk in a totally different manner from English people. They seem to be burdened with no lurking fear of there being danger in making a pleasant acquaintance—they do not appear to wish to know even your name. Smith is to them equivalent to Brown, if only Smith will exchange his ideas in return for the unreserved pouring-out of the treasures of their own well-stored minds. I have never known an English gentleman do this. He is always perfectly polite; but why should he trouble himself about a stranger he will never see again—a nobody? He has plenty to think about, probably others have the same.

But to return to my trowel, to which amongst other things I owe two beautiful clumps of *Septentrionale*.

In the course of our wanderings, after "doing" the Caledonian Canal, and searching in vain for *Hymenophyllum unilaterale* at the Falls of Foyers, and making many a pretty addition to *Cystopteris* from the Muir of Ord, we arrived at Dunkeld, that loveliest of all lovely halting-places, where hill and valley, rock and river, contend with each other in sweetest rivalry as to which shall lend the greatest charm to the scenes around. About two miles from Dunkeld is the Stenton Rock, and growing there side by side may be found *Asplenium septentrionale*, *A. germanicum*, and *A. trichomanes*.

Trowel in hand, I marched off to hunt. "Where

awa?" said an old road-scraper to me; "ye'll be seeking for something, nae dout." I explained I was going to Stenton for Ferns. "Weel, weel, ye'll find them unco high, too high for a leddy, maybe."

The old road-mender was right. I returned hours after, wet through with what in pleasant mockery is called Scotch mist, but Fernless. "Ye'll hae been disappointed," said my old friend when he caught sight of me. "Ye come to me the morn and I'll see. I live at Stenton, ye'll hae seen my hous for bye the rock."

The next day I kept my appointment; and my friend, true to his word—for he was a very Scot—had two large clumps of *Septentrionale* for me. "Oh, leddy," he said, "the gran gardeners hereaboats hae taen all the ither sort, and I could nae find ye one root."

When I offered the old man a shilling he answered, "Nae, nae, keep your siller, I am glad to hae pleased ye."

And I was pleased, for never have I seen in England such plants of *Septentrionale* as these. They were no unhealthy-looking scraps picked off the face of the rock, but compact tufts (one of them mixed with *A. trichomanes*), of 3 or 4 inches in size. Much has been written about the difficulty of managing *Septentrionale*, but I have hitherto found none. I planted these specimens (considerably reduced by gifts to friends), in an open fernery facing the south, and they came up year after year luxuriantly and well, but they do not increase.

Asplenium germanicum is said to grow on the Stenton Rock, as well as the *septentrionale*: I was shown a plant of it; the tiny forked fronds were about 1½ inch in size, and not so broad as *Septentrionale*, the forked ends being almost as fine as a thread. I have never possessed this Fern, nor have I ever seen a healthy specimen of it, or one I should know as perfectly distinct from *Septentrionale*; indeed, I believe the plants shown to me as *germanicum* have only been diminutive specimens of *Septentrionale*.

From the Stenton Rock in the cold north my mind wanders to the sunny south, where, under conditions somewhat similar, and yet how widely different, I have seen at Bagneres de Luchon in the Hautes Pyrenees, the entire face of a rock, in the very eye of the sun, entirely covered with *Septentrionale*: the fronds were nearly double the size of our English Fern, and the forked ends one mass of rich brown spores.

I seldom look at *Septentrionale* without being, in thought, carried away to beautiful Luchon. I seem once more to be by the side of the Fern-covered rock. It stands jutting out on the road leading into Spain, down which gaily-dressed muleteers are driving their mules, laden with wood for the winter's use; the merry bells are tinkling in the air as the poor mules shake their heads under the heavy burden. On my left hand are jagged rocks, whose crevices are gay with wild flowers; on the right are Beech-covered hills, with pretty châlets dotted about here and there, slanting down to the town, with the river, lined with golden Poplars, flowing through. Before me, in the far distance, is the Port de Venasque, its snow-capped peaks glitter like diamonds in the sun, and seem to sparkle with delight at the glorious scene stretched out beneath them in the fair land of Spain. I inhabited one of those châlets on the Beech-covered hill. The garden is a very wilderness of flowers, and in this wilderness there is a little oratory with a statue of the Blessed Virgin, whose shrine is always decked with flowers, and the hand that places them there is the rough toil-stained one of the old housekeeper, Jeanne.

"My mistress used to put them there," she said; "but she died when the little miss was born, and now there is only me."

Good old Jeanne! with her hard features and tender heart! whose only outward religious observances seemed to consist in placing the flowers and in sundry crossings of herself. How much I used to enjoy our shoppings and marketings together in the early morning; Jeanne's head coquettishly adorned with a brilliant amber kerchief, tied in a dainty knot on one side, and she herself trying, with unexampled patience, to make me a proficient in (her) French, which consisted of a most bewildering patois of Spanish and French mixed together in one confused mass.

I have never found *Septentrionale* growing in the shade, nor do I believe it could endure such a situation; it luxuriates

in warmth and sunshine, and does not care for much water. The one great point in cultivating it is thorough drainage; if there is any moisture hanging about, the base of the fronds will decay, and gradually fall off, and a tiny wireworm will come to help in the work of destruction. When the least decay is visible in the fronds, dig up the plant, and look to the drainage.

At Dunkeld I found quantities of very fine *Ruta muraria* growing in the old wall of the Duke of Atholl's park. I managed to pick out a great many roots with considerable portions of earth attached; but, alas! I have never made *Ruta muraria* live for more than two years in cultivation. I have tried it with old mortar, planting it upside and downside and every way, but all to no purpose; I am now trying it in a flower-pot nearly filled with drainage, placing the flower-pot sideways in the fernery, and covering it with earth.

The Duke of Atholl's grounds are strictly preserved, and I have a strong aversion to going over houses and grounds with a bought permission, so one day I determined to enter them as a freebooter. I was stopped by a little fellow.

"Ye'll nae be ganging there," he said; "it's the Duke's private walk."

"But supposing I'm the Duchess," said I.

"Weel, if ye're the Duchess ye maun go," said the boy; and then, amazed at his own temerity, he ran off, leaving me to retrace my steps.

On the road between Dunkeld and Aberfeldie I found a very beautiful variety of *Athyrium Filix-femina*, some of the fronds were nearly 2 feet in length, the stipes of the younger fronds were of a pinkish brown, and very bare, the pinnae were thrice-pinnate, and the whole Fern had a graceful feathery look. I have since seen what I believe to be the same Fern under the name of *Filix-femina plumosum*. I found it not far from the pretty waterfall called the Bumbling Bridge, where troops of merry children meet you with baskets and pinafors full of rich dark red Bilberries, and the far-off distance has at eventide the sunny glow of the south falling on ruddy banks of Heather.

I found *Lastrea spinulosa* in many places in Scotland; it must be hunted for in shady nooks, where it grows side by side with *A. Filix-femina* and *Blechnum spicant*. Mr. Bree gave me a very curious specimen of *L. spinulosa* which he found growing on the Coleshill bog; the stunted frond was little more than a foot in size; in colour it was a sickly-looking greenish yellow. Mr. Bree also gave me a frond of the very same root when cultivated, and it would have puzzled any one but a close observer to have known they were the same Fern; and it is this altered aspect of Ferns under altered conditions that makes their study bewildering to a beginner. I dare not venture to say that *L. spinulosa* under any conditions would turn into *L. dilatata*, but it looks uncommonly like it; and you find varieties so nearly approaching both Ferns that it is difficult to name them. This difficulty does not exist with *Lastrea uliginosa*, the under pinnales of *uliginosa* being the same size as the upper ones. *Uliginosa* seems to approach nearer to *L. rigida* than any other Fern, and yet on placing the two side by side it would be impossible to mistake one for the other, the entire growth of *uliginosa* being taller and much more robust, while the pinnae are much farther apart.

Lastrea rigida I have never found, so I have been reduced to the necessity of buying one; and of all my Ferns I have found *rigida* the most tormenting to deal with, its likes and dislikes are as many and as unaccountable as those of a wayward child. When I bought the plant of an amateur dealer for 3s. 6d., it consisted of a nest of brown fronds, with one withered frond about half a foot long, and two little deformed fronds by its side. It was very unpromising, and my friend the dealer assured me it was an illnatured subject that repaid all your care by giving you nothing but those black looks. I did all I could for the "ne'er do weel." I made it a lovely home with well-drained fine leaf mould for its food; but a year passed, and its new fronds were dwarfed, dark, and illnatured-looking; moreover they were evidently rotting away. I looked for the reason, and found a large Fern, planted above *rigida*, dropping some of its surplus wet upon it. I moved it to a clearer place, and at last I gave satisfaction. I housed it in winter, and planted it in a clear sunny spot in summer, protecting the young fronds as I do those

of *Polystichum lonchitis*, and it has rewarded me beyond my expectation. It has now a crown of healthy fronds covered with fructification, and it has thrown out two young plants at its side: when these are well established I shall try the parent Fern out of doors all the year, covering it with litter during hard frosts.—*FILIX-FÆMINA.*

THE FRUIT-ROOM.

It is certainly much to be regretted that although most structures intended for horticultural purposes have received their full share of attention, and the most approved modes of erecting them have been at times ably discussed in this Journal and other gardening works, the fruit-room has scarcely ever received a passing notice. Assuredly this cannot arise from the indifference with which it is regarded, for it is of the utmost possible importance; but somehow fruit-rooms, generally so called, form such uninviting features in most gardens that they are never visited by fashionable company. That this should be the case is unfortunate; for a nice collection of Apples and Pears in the month of November is as well worth inspecting as anything the plant-houses contain at that time; but when a makeshift of a shed, or some hovel no longer of any other use, has to be put in requisition for the purpose of keeping fruits, those having the management of it naturally shrink from inviting any one to see their collection when huddled together in such humble quarters. They nevertheless manage now and then to keep their fruit pretty well in such houses or sheds, and not unfrequently better than is sometimes done in structures of greater pretensions, and we are, therefore, led to inquire if there is not something wrong with the latter, and a careful investigation into the matter confirms the suspicion that this is really the case. The subject of keeping winter fruit being so important, let us examine the elements which either lead to success or the contrary.

When we look into the mode which Nature adopts to insure the reproduction of each species, we find that all seed-vessels or receptacles have a function to perform, and when this is accomplished they perish. Some seeds are scattered abroad by the bursting of the seed-pod, and by a jerk thrown some distance. Others are clothed with down, and dispersed far and wide by the wind. Others depend on their removal being effected either by birds, animals, or some similar agency, and of such, perhaps the Apple and Pear may be accounted examples, while they also exhibit the seed enclosed in a fleshy substance capable of resisting decay for a greater or less period—in the wild ones, certainly until the proper time for depositing the seed in the ground; and assuming the fruit to fall where it is grown, the conditions for its keeping are prepared for it by natural means. Dead leaves and herbage form a sort of nest as well as a covering, securing the preservation of the seeds until the appropriate time for their being deposited in the earth. Our object, however, is the preservation of the fruit, and the seed is no further regarded than as being a component part of the fruit; but as Nature has shown us that a cool and far-from-dry medium serves all the purposes of keeping the fruits spoken of through the inclement part of the winter, we may not be far wrong in copying to a certain extent some of the conditions thus laid down.

It being shown that a cold medium is the best to prevent decay in the fruit now under consideration, the question naturally arises, How is a cool atmosphere to be obtained? To a certain extent we have but little control over the temperature, for though we might increase that of the atmosphere of the room, we cannot easily diminish it; but something may be done in the latter way, or, at all events, the evils of overheating our fruit-rooms may be avoided. To cram a house with Apples and Pears in the warm weather of the early part of September is making it little better than a pest house, especially if there be very little ventilation; for the quantity of fruit lying in so confined a space engenders heat, or, what is equally bad, vapours are given out that are anything but favourable to the preservation of the fruit. Yet how common it is to crowd the fruit-room so early in the season. Apples keep falling, and birds and wasps attack the Pears, and, consequently, there appears to be no alternative but covering the shelves with fruit, perhaps

three or four thick. Ripening takes place with more or less rapidity in consequence of the forcing to which the fruit is subjected, the close stifled state of the room, and the warm condition of the external air hurrying on the ripening, and ultimate decay, of the whole of the fruit there collected.

Assuming, therefore, the position in which Nature often deposits her fruits to be on the whole favourable to their keeping (and we often see that an Apple which has fallen softly amongst long grass or other herbage exhibits as high a state of preservation when found there in winter as others of its kind when housed in the ordinary way), we are led to consider that plenty of fresh air is by no means unfavourable to the keeping of such fruits. On this account, therefore, our fruit-rooms ought to be well ventilated, and they ought not to be too low, or if from circumstances they must be so, they should be ventilated at top as well as at the sides and ends. The best form for a fruit-room when it stands alone is an ordinary span-roof, of tiles laid on dry—that is, not embedded in mortar in the usual way; below the rafters the roof may be ceiled halfway up following the inclination of the rafters, with a flat space of some 3 or 4 feet in the centre, in which a latticed ventilator may be fixed, the latticework very open, and extending the whole length of the room. There should be a sort of contrivance for closing the latticework—a board, say on hinges, like a long trap-door. This is better than sliding latticework, as the latter is apt to get out of order, and is not easily moved. The tiles, being open, will allow all vapours that find their way into the apex of the roof to pass through, and the ventilator will only require closing in very severe weather. In dry situations it would also answer as well to have the house partly underground, say 3 feet or so; this tends to keep the temperature more equable, and in the hot dry weather of the dog-days is certainly a relief from the heated air outside. The side and end ventilators may be of glass, not allowing, however, any windows to the south, and for the same reason it would be better if the building were shaded from the mid-day sun in that direction, buildings being better for that purpose than trees. The situation ought also to be unconfin'd, and free from all noxious vapours and damp exhalations. The internal fittings might be in the usual way, a series of shelves all round, and a table shelf in the centre, and if the latter had drawers in it so much the better. The shelves ought not to be too close above each other—four or five in a tier is quite plenty—the highest one being at least 7 feet from the ground. It is customary to make the shelves partially open, but I am not certain that this is required. One of the best-keeping fruit-rooms I ever had to deal with had slate shelves, close and impervious. Care, however, was required not to allow the fruit to tumble about on a shelf so hard. I am no advocate for straw, or anything of that kind, under the fruit.

There are many conditions in which fruit has been kept tolerably well, and for a long period. A cool cellar is not by any means a bad place, only the quantity ought not to be large, or ventilation must be obtained; but the currents of fresh air that are wanted in September, may in a great measure be dispensed with in December, or, at all events, much less will do. A cellar is better than a great many fruit-rooms. I have also retarded some fruit in an ice-house and kept it later there than it would have kept in another place, but the propriety of retarding fruits, excepting for special purposes, is much questioned; certainly the flavour is deteriorated. I have also seen a quantity of Apples buried in the ground like Potatoes. This was merely for an experiment, and the result was that many of them burst, much the same as a Potato will when boiled with the peeling on. Keeping them in a chalk-pit or cave approaches so much to the cellar that it may be classed as the same. Sheds of all kinds are used to store Apples in most places where they are grown abundantly, and in Kent thousands of bushels are kept in heaps on the floor of the hop-drying kilns, which, being lofty and airy, are by no means bad places. The great misfortune is, the fruit is often laid in heaps from 2 to 3 feet thick, and a little straw thrown over it in severe weather. Keeping Apples in air-tight boxes or jars has been abandoned of late years, and casks of various kinds are occasionally used, but more frequently for transporting fruit than for storing it away. Although Apples will occasionally keep a long time under conditions different from

those now given, it is not to be inferred that these methods are better, as the fruit might, perhaps, have kept a little longer if fairly tried in the way described.

Before closing these remarks I may observe, that as fruit ripens earlier in certain seasons than in others, and in some is charged more abundantly with those juices which promote decay, the keeping is not always alike, even when attempted in the same way. A well-perfected fruit may be as forward one season by the 1st of September, as it will be in another by the end of the same month; while it is almost needless to observe, that the ripening, and, consequently, decaying influence of a warm month like September tells more than an equal length of time later in the year. It is not too much to say, that the thirty days in September ought to be accounted equal to the fifty days that next follow, taking, of course, average seasons. Hence, fruit that ripens so much earlier than usual has but a poor chance of keeping well if the weather be warm. Those, therefore, that want to prolong the season of any particular fruit must keep it as cool as they can, and success will be in accordance with the reduced temperature, all other conditions being favourable. In a general way, the place most conducive to the good-keeping of fruit is similar to that which preserves milk—one with a cool atmosphere and abundant ventilation, and free from all vapour, bad smells, and stagnant air of all kinds. In fact, a fruit-room ought to be as sweet as a dairy.

J. ROBSON.

THE NEW ROSES.

WHEN one passes away from the region of what one has seen in the matter of flowers to what one has heard, it is very much, I fear, as great a change as from fact to fiction. And certainly there have been few writers of fiction who have excelled some of our French friends in their descriptions; for seeing their glowing accounts of their novelties and seeing the novelties themselves are two very different things, one being too often but the "counterfeit presentment" of the other; and I can conceive nothing more galling than for a nurseryman to be compelled to throw away dozens of plants which he had propagated with so much care and trouble in the belief that they would be sought after. I therefore feel more than ever the difficulty of forecasting as to the probable value of the eighty and odd new Roses now offered. In truth it must be the merest conjecture, and chiefly dependant on one's knowledge of the growers and their previous exploits. We may thus speak hopefully of what a Verdier, a Margottin, a Lacharme, or a Guillot may produce; while a Touvais, a Fontaine, or a Moreau will not inspire us with much confidence. I shall therefore simply give the names with the descriptions of the French raisers, and such conjectures as may occur to me from my previous acquaintance with the Roses of former years.

GUILLOT FILS.

21. *Abbé Berlèse*.—Full flowers, well formed. Colour changing from a reddish cherry to carmine rose.

22. *Madame Rousset*.—Full, beautiful tender rose; reverse of petals silvery.

23. *Souvenir de Bernardin St. Pierre*.—Full flowers, well formed, imbricated. Colour varying from a velvety crimson rose to slaty-red violet, with the centre a shaded red. I have heard a good account of this Rose from Mr. G. Paul, who told me he saw it at Lyons. It is evidently much thought of by the raiser; and from the description, which would refer it rather to the class of such flowers as André Leroy and Mrs. William Paul, I should be inclined to think favourably of it.

GONOD.

24. *Achille Gonod*.—Full flowers, well formed. Lovely carmine red.

25. *Madame Hermann Stenger*.—Flowers full, well formed, standing well on the plant. Beautiful rose, shaded with sulphur in the centre.

26. *Madame Moreau*.—Flowers full, Peony-formed, and convex; outer petals very large. Colour clear lively red, shaded with violet.

Of these there is something novel in the description of the last flower, and it may be possibly good; but the description rather inclines one to fear that coarseness may prevail in it—a fatal defect to a Rose.

PORTEMER FILS.

27. *Charles Wood*.—Flowers full, very well formed. Very dark red shaded with black.

28. *Jean Rosencrantz*.—Flowers full, well formed. Lively coral red.

The first of these reminds one of Lord Macaulay, a flower of the same raiser's. I hope it may be worthy of the rosarian whose name it bears, for it will then be what the boys call a "stunner."

TOUVAIS.

29. *Belle Rose*.—Very vigorous. Flowers full, globular, opening well, of irreproachable form and appearance. Clear rose, very fresh!

30. *Semiramis*.—Flowers full, globular, good form and appearance. Tender flesh rose.

31. *Souvenir d'une Mère*.—Vigorous. Flowers full, flat, large petals; tender rose at the outside, centre lively cerise. Very fragrant.

Notwithstanding the wonderful description given of 29, the former productions of Touvais have not given me much confidence in looking for anything very wonderful from him, for I do not know any Rose of his that is now a general favourite.

TROUILLARD.

32. *Baptiste Desportes*.—Vigorous. Flowers large, full, and well formed. Lively shaded red.

33. *Constant Lussan*.—Vigorous. Flowers medium full, well formed. Beautiful clear red, passing into violet.

34. *L'Abbé Laury*.—Vigorous. Full, well formed. Lively red, shaded.

35. *Loïde de Faloux*.—Vigorous. Flower large, full, well formed. Blush white.

36. *Madame André Leroy*.—Vigorous. Nearly full, well formed. Salmon rose.

M Trouillard is the foreman of the well-known nurseryman M. André Leroy, of Angers, and has been for many years known as a Rose raiser, although his flowers have generally come to us through Mr. Standish, of Ascot, who has purchased generally the stock, but finding, as I believe, that they were not generally up to the mark, he has given this up, and hence M. Trouillard comes out on his own account. His flowers generally want fullness of shape, and of those which Mr. Standish has let out belonging to him, there is hardly a flower, save Eugène Appert, that has risen to the position of a general favourite, and that sadly wants regularity of form, the outline being very imperfect, while André Desportes, Reynolds Hole, Madame Standish, Marguerite Appert, and others, must be numbered, I fear, amongst the things of the past.

OGER.

37. *Belle Normande*.—Vigorous. Very large, globular, tender rose, silver shaded. A sport of La Reine.

38. *Général de Miandol*.—Vigorous. Flowers large, full, and globular. Velvety purplish red.

39. *Marie Boissée*.—Vigorous and very free-flowering, well formed. Blush rose, passing to pure white.

DUCHER.

40. *Marie Perrachon*.—Moderate growth. Flowers large, full, imbricated. Violet shaded purple.

41. *Rosa Mundi*.—Full, vigorous. Flowers very large, well formed, virgin rose.

42. *Vase d'Election*.—Moderately vigorous. Flowers very large, very full, cupped, well formed. Clear rose.

MOREAU.

43. *Adelaide de Savoie*.—Flowers medium, cupped, well formed. Tender satiny rose.

44. *Edouard Ory*.—Flower full, globular. Beautiful vermillion red.

45. *Prince Eugène de Beauharnais*.—Vigorous. Flowers large, well formed. Clear red, reflexed with purple.

46. *Telemaque*.—Flowers medium, flat. Velvety purple, strongly shaded with red.

FONTAINE.

47. *Madame Léonie Persin*.—Very vigorous. Flowers large, full, globular, well formed. Pale blush.

48. *Mons. Pierson*.—Very vigorous. Flowers large, full, well formed. Amaranth rose, flushed with crimson.

49. *Roi d'Espagne*.—Vigorous. Flowers large, full, well formed. Clear red, reflexed with purple.

50. *Rosine Ravaux*.—Vigorous. Flowers large, full, well formed. Lovely rose. The edge of the petals silvery.

DAMAZIN.

51. *Jules Lavay*.—Very vigorous. Flowers large, full, well-formed, beautiful flesh rose, very glossy, and very free-flowering.

52. *Ninon de Pontbriand*.—Plant very vigorous. Flowers full, very large, well formed. Brownish crimson, shaded with carmine.

I cannot say that I entertain any very high opinion of the above Roses, and simply for the manner in which the raisers have deluded us in former years. It may be they will not do so now, but a burnt child dreads the fire, and we must wait to see. I hope to conclude the lists next week.—D., Deal.

AGRICULTURAL HALL CHRYSANTHEMUM SHOW.

THE Metropolitan Chrysanthemum Society held their annual Show at the Agricultural Hall, on Wednesday, Thursday, and Friday last, when the exhibitors were numerous, the display extensive and fine, and the attendance of visitors good, notwithstanding the very unfavourable weather which prevailed on the first two days. Last year the mistake was made of extending the Exhibition over too wide an area by which the effect was seriously impaired, most wisely, therefore, the attempt was not made to fill the acres of covered-in space which the Agricultural Hall affords, but the Show was confined to the minor hall, Lower Road entrance, and part of the adjoining area. The result was, that the effect of the display was much enhanced, and the innumerable blooms—red, white, yellow, and a host of intermediate shades, especially when viewed by gaslight, combined to form a brilliant scene.

There were upwards of forty classes—classes for nurserymen, classes for gentlemen's gardeners, classes for amateurs, classes for Islington, and classes that were open to all. With but few exceptions there was competition in all, and in many of them as many as four or five prizes were awarded. We would here suggest what we consider would be an improvement—namely, instead of having five classes numbered 1, and a like number distinguished as 2, and so on, to have them all numbered consecutively from first to last, and this, without interfering with the sections as at present constituted, would prevent all danger of confusion and mistake.

LARGE-FLOWERING PLANTS.—Of these Alma, Prince Albert, Lady Hardinge, Christine, Golden Christine, Annie Salter, Arigena, Defiance, and Jewess were the kinds principally shown. In the Nurserymen's Classes, Mr. Forsyth carried off the principal prizes; his specimens were noticeable for their fine bushy growth and abundance of bloom. He likewise took the first prize in the Open Class for the best single specimen, with a magnificent plants of Christine; Mr. D. Monk being second with a very fine plant of the same kind. A group comprising excellent specimens both of large-flowering kinds and Pompons, was also contributed by Mr. Forsyth. Among the latter were several fine close-headed standards with three-feet stems, which had been grown from cuttings put in last March. In the Gardeners' Class for six, Mr. D. Monk, gardener to J. Leschalles, Esq., Page Green, was first with a splendid plant of White Christine, 4 feet across, and bearing, probably, not less than two hundred blooms; Defiance, usually starry, but not so in this instance; Golden Christine, Annie Salter, Alma, and Beauté du Nord. Mr. Ward, gardener to W. Fowler, Esq., Tottenham; and Mr. Glover, gardener to R. Lepage, Esq., Tulse Hill, were second and third, with excellent specimens. Mr. Monk was first for three, with Golden Eagle; Annie Salter, beautiful; and Sparkler, red and orange, very full of bloom. Mr. J. Glover was second; Mr. Beecher third; and Mr. George fourth. Mr. Parker, Stratford, had Golden Christine, very fine; and we noticed a group of tall plants in fine bloom from Mr. Orson, including Jardin des Plantes, Beverley, General Hardinge, &c., bearing large and fine blooms. Excellent groups were also furnished by Messrs. Rowe & Glover.

POMPONS.—Of these Mr. Forsyth contributed several very

fine specimens grown in a more natural style than that which almost universally prevailed two or three years ago; his specimens, instead of being trained out almost flat on wire, had rounded heads; among them Lilac and Golden Cedo Nulli were remarkable for their size and abundance of bloom. The exhibitions of Messrs. Ward, Beecher, Bolton, Parker, Glover, and others, included many beautiful examples of Général Canrobert, Golden Cedo Nulli, Golden Circle (a fine new yellow), Lilac Cedo Nulli, Andromeda, Salamon, Duruflet, and Lilac Cedo Nulli. From Mr. Butcher came six nice pyramids, of which Général Canrobert, Cedo Nulli, and Golden Cedo Nulli, were covered with bloom.

CUT BLOOMS.—These were very numerously exhibited, and for the most part in great perfection. To attempt to give the names of all the varieties in each of the different stands in upwards of twenty classes, would be attended with little if any benefit; and we will, therefore, only notice the kinds that were principally shown. Among *Whites* were splendid examples of Mrs. W. Holborn, Beverley, White Globe, Empress of India, and Lady St. Clair. Among *Yellows*, Jardin des Plantes stood pre-eminent, and in many of the stands was of extraordinary size; of *Orange*, Bernard Palissy, Antonelli, Golden Hermione, and General Bainbrigge, a new and very fine orange amber; of *Red shades*, Lord Ranelagh, St. Patrick, Nil Desperandum, Oliver Cromwell, Rev. Joshua Dix, new orange red; Sir Stafford Carey, also new, a brown chestnut tipped with gold; of *Rose*, *Lilac*, *Blush*, &c., Queen of England, Alfred Salter, Arigena, Themis, Hermione, Beauty, Lady Slade, and Her Majesty. For twenty-four, first prizes were taken by Messrs. Monk, Merry, and Hilleary; and second prizes by Messrs. Forsyth, Slade, and Rowe. For twelve, first prizes by Messrs. Moxham, Monk, Robinson, and Saltmarsh; and second prizes by Messrs. James, Rowe, and Delvalle. For six, first prizes by Messrs. Delvalle, and Monk, of Chelmsford; and second prizes by Messrs. Howe and J. Monk. Besides the above there were classes for thirty-six blooms of twelve varieties shown along with the foliage, in which many splendid flowers were seen, especially in the stands of Mr. Forsyth, Mr. Allaway, who had Jardin des Plantes magnificent, Mr. Butt, and Mr. S. Monk.

In addition to the above, numerous other prizes were awarded in the various classes to Messrs. James, Moxham, Robinson, Peasgood, George, Ward, Rowe, Brown, and others.

Of new varieties of the current year, we noticed Robert James, a finely incurved cinnamon and orange; Prince Alfred; Princess of Wales, a beautiful white, tinged more or less with lilac; Rev. Joshua Dix; and General Bainbrigge, dark orange amber. For the latter, special prizes, offered by Mr. Salter, were awarded to Messrs. Moxham and Rowe. Princess Dagmar, a large-flowered Pompon Anemone, which was shown at Stoke Newington, was again exhibited by Mr. George. Two promising Anemone seedlings, Gem of the Valley, blush; and Prince of Anemones, shaded lilac, came from Mr. Brown, of Great Marlow. Large-flowering Anemone varieties, consisting chiefly of Gluck, orange; Louis Bonamy, lilac; Lady Margaret, white; Madame Godereau, sulphur; and Marguerite d'Anjou, nankeen, were well shown by Messrs. Hilleary, Butt, Saltmarsh, Ward, Monk, Merry, Moxham, Forsyth, Massey, France, and others, most of whom also contributed extensive collections of Anemone Pompons.

Prizes were offered by A. Smee, Esq., for the best collection of Chrysanthemum flowers, intermixed with Ferns, or other foliage, for the decoration of the dinner-table, and a pretty design from S. Hill, Highgate, stood first. It consisted of a glass stand, with Begonia leaves, interspersed with Adiantum, and Chrysanthemum blooms at the base, and the top dish, edged with Isolepis gracefully hanging down, and filled with Chrysanthemum blooms. Mr. George was second, with a design somewhat resembling the preceding. For the decoration of the Hall, the walls of which were hung with swags of foliage and flowers, Mr. Williams contributed a number of choice ornamental-foliated plants, &c.

BIRMINGHAM CHRYSANTHEMUM SHOW.—The Handsworth Floral and Horticultural Society propose to hold their third great annual Exhibition of Fruit and Chrysanthemums at

the Birmingham Town Hall, simultaneously with the Poultry and Dog Shows. The two previous displays which have taken place in Birmingham, were not only extensive, but beautiful; and there is every reason to anticipate that the one now about to take place will be greatly superior to them.

TRENTHAM BLACK GRAPE.

In your issue of the 8th inst., Mr. J. R. Pearson strongly recommends the Trentham Black Grape for an orchard-house. Has he grown it in a cool house? He says, "In the hothouse the Trentham Black is a first-rate early Grape. We cut about 40 lbs. from a young Vine this season, &c." We have one Vine of Trentham Black in an orchard-house, and as far as I can judge it is not at all desirable for that position, being a bad setter; scarcely two-thirds of the berries swell to their proper size, being stoneless. The remainder are large oval-shape berries, with a thin skin of a bluish black colour, flavour excellent, superior to any Hamburg, and good bunch; but being a bad setter must detract much from the value for an orchard-house. I have no doubt it is good in heat. The berries grew uniformly to the size of peas, when they were thinned, and there they remained until colouring, when they reached the monstrous size of a Black Cluster. The few which grew on are the size of a good Muscat of Alexandria. The Vine was supplied by a highly respectable firm, and I have no doubt about its correctness. Should I be in fault and not the Grape, I shall be very happy to be placed on the right footing. In Mr. W. Paul's notes on his tested varieties, he places Trentham in a doubtful position, and so do I. Black Hamburg by its side is superb.—GEORGE BESTER.

[We should be obliged by having the results of the experience of other correspondents upon this point.—Eds.]

PILLAR ROSES IN A CONSERVATORY.

I HAVE read with great delight the account of Envile Hall and its extensive gardens and pleasure grounds. There seems to be everything that heart could wish, but one thing. A conservatory is spoken of. I do not know its construction. If there are two lines of pillars and a broad walk between, as Lord and Lady Stamford are fond of Roses, especially of Tea-scented Roses, I think that they would be delighted with Tea-scented Noisettes, strong-growing Tea Roses, strong-growing Bourbons, and Hybrid Perpetuals, planted so as to run up the pillars. I cannot conceive anything in the Rose way that would be more transcendental. I give a list of Roses that would be well adapted to such a purpose. If I were a rich man I would build a long glass house, say 300 feet in length, if it were only for this purpose. The other part of the house might be filled up with trees in pots, or with Tea and other Roses, either in pots or planted out. There is nothing in the Rose way that will surpass for abundance and continuity of blooming the Tea-scented Noisettes against south walls out of doors, or Tea Roses and Tea Noisettes under glass.

TEA ROSES, Light Colours.—*Devoniensis*, *Sombreuil*, Madame Willermoz.

TEA-SCENTED NOISETTES, Yellow Roses.—*Cloth of Gold*, *Solfaterre*, *Triomphe de Rennes*, *Gloire de Dijon*, *Celine Forestier*, *Lamarque*, *Mdlle. Aristide*, called also Madame Schultz.

These are splendid Roses for such a purpose. If more yellow Roses are desired, the two Tea-scented Noisettes Isabella Gray and Jean Hardy, and the four Tea Roses Elise Sauvage, *Vicomtesse de Cazes*, *Louise de Savoie*, and *Safrano*, may be added to the others.

BOURBONS, Light Colours.—*Acidalie*, *Souvenir de la Malmaison*. Light Crimson.—Sir Joseph Paxton.

HYBRID PERPETUALS, Very Dark.—*Prince Camille de Rohan*, *Duc de Cazes*, *Princesse Mathilde*. These are strong growers, beautiful, and never out of bloom.

Rose Colours.—Anna Alexieff, *Baronne Prevost*, *La Ville de St. Denis*, *Duchesse de Cambacères*, *Madame Boll*.

Blush.—*Caroline de Sansal*.

Shades of Crimson.—*Jules Margettin*, *Madame Louise Carrique*, *Duc de Rohan*, *Maurice Bernardin*, *Maréchal Vaillant*,

Madame Julie Daran, *Senateur Vaisse*, *Général Jacqueminot*, *Madame C. Crapelet*, *General Washington*, *Monsieur de Montigny*, *Géant des Batailles*.

These are all fine Roses, and adapted to the purpose. Moreover, with the exception of *Safrano*, *Mdlle. Aristide*, and *Princesse Mathilde*, they are all show Roses. Some of the Roses named are strong-enough growers to run up a pillar of any height, and meet one another in the form of an arch—namely, *Gloire de Dijon*, *Cloth of Gold*, *Solfaterre*, *Lamarque*, *Triomphe de Rennes*, *Mdlle. Aristide*, *Acidalie*, *Souvenir de Malmaison*, *Sir J. Paxton*, *Madame Louise Carrique*, the best H.P. climber, and *Duc de Cazes*, the best dark climber. The pillars might be planted with three plants of similar growth and habit, in contrast of colours if so desired.

I am not much for mixing colours, but rather for condensation. As regards climbing Roses, it is not every Rose that will run up a pillar that will fulfil all the conditions of a pillar Rose. A pillar Rose to be first-rate, as a tree, should cover its stalks with flowers and leaves. Probably no trees fulfil this condition better than *Ophirie*, *Mdlle. Aristide*, *Anna Alexieff*, and *Madame Louise Carrique*. One thing is plain, that persons should be careful not to cut away the wood from the base and centre of strong growers. In due time, under any circumstances, they will become bare. In such case they must be cut down and let up again. I am persuaded that any person trying the above plan, and selecting any, or using all the Roses named, for the purpose stated, will be highly delighted.

I have just received a letter from Mr. W. Paul, in which he informs me of the distinguished names of the members of the Horticultural Club who drank my health enthusiastically on my birthday, Nov. 8th. I embrace this opportunity of thanking them—thanking them heartily.—W. F. RADCLIFFE, *Rushton*.

CULTURE OF TRITONIA AUREA.

I SEE that a correspondent is advised in a recent Number of the Journal to keep the *Tritonia aurea* dry at one time, as being a bulb requiring rest.

Confident that the above is not the treatment which may be most successfully followed, I am induced to make the few following remarks upon a successful mode of culture.

The *Tritonia aurea* is strictly an evergreen bulb, and should be treated in practice as such. Immediately the plants have done flowering, and the foliage is showing signs of ripening, cut them down, and pot them as advised; after which give them a good soaking of water, and do not let them become dry until they again show signs of flower, when they will not need so copious a supply as when growing vigorously. They require a rather liberal shift to grow them well, or they may be carefully divided. When potting them, it will be seen that at least two, and in some cases three, underground growths have started from each of the bulbs; to encourage these with water, &c., will be to insure to each a good strong flower-spike from 2 to 3 feet in height; whilst to dry them at all at this period will be to arrest their growth, and dependance must then be placed on the old bulbs alone, which these strong growths from the base of each have already so greatly impoverished. This is the cause of the many poor-looking pots we often meet with averaging from 7 to 9 inches high, and with very little flower.—W. EARLEY, *Digsowell*.

[The *Tritonia aurea* with us dies down completely once annually a short time after blooming, and there is no green shoot then for some weeks to indicate its evergreen character. We were in the habit of considering such bulbs strictly deciduous, and we did not know that continued root-growth without visible foliage constituted what we recognise as an evergreen, be it ligneous or herbaceous. It may be so: then all plants are such; for there is none that does not increase at root while in a state of rest more or less before the reappearance of the foliage.

We are well aware of the fact that it is extremely injurious to keep the roots of *Sparaxis*, *Tritonias*, &c., at any period in a dry state for a length of time, either when growing or in a state of rest; but the idea that the *Tritonia aurea* requires to be kept constantly growing is not correct;

for there is no plant that can be kept healthy without an annual period of rest, whether that rest be effected through dryness or through cold.

According to our correspondent's description of his treatment it would seem that he treats the Tritonia as an aquatic during the winter, lessening the quantity of water when the plant shows for bloom, when it seems it should be allowed to become dry, or not be watered so copiously as when growing vigorously during the winter. Surely a blooming plant should be well watered when showing for and in flower!

We pot them, when the foliage turns yellow, in soil moderately moist, and place on coal ashes out of doors—it may be in a frame. When the flower-spikes are quite gone we cut them away, and we do not pot until then, if any increase is desired; and after potting new roots we water them to settle the earth about the roots. We plunge them, whether divided or undivided, in coal ashes in a cold frame in October, before frost sets in. Air is daily given during mild weather, and a protection of mats sufficient to prevent injury from frost. No water is given during the winter, from October to March, for there is moisture enough in cold pits, and cold greenhouses too, to prevent the young shoots, as yet under ground, deriving their sole support from the root-bulbs. Were they watered as our correspondent recommends, and should they be frozen with the soil in the state of mud, as it will be through constant watering, we should find the roots as if parboiled—those young shoots our correspondent is so careful about as to give soakings of water to. After growth has fairly commenced in the spring we water copiously, and continue to do so until the flowering is passed, when the plants are repotted, and treated to no more water or moisture than what they receive by being placed or plunged in coal ashes. So opposite is this to the treatment recommended by our correspondent that we have entered into it at length, not to show that he is wrong, but to prove that circumstances alter cases; and in answering correspondents' queries special cases are the rule rather than the exception, and no one can form an opinion of the answers unless the query be before him. We have another mode of treatment, different only because the plants are wintered in a heated structure, and this consists in our keeping the pots on the floor in the coolest part of the structure, and with the moisture absorbed from the damp floor, very little water is necessary to prevent the soil becoming dust dry, but if it should become very dry we give a little to prevent the roots drying up. We keep them dry, but not dust dry, and the result is we have our plants with 178 spikes of bloom, about 4 feet through, and between 3 and 4 feet high, and not those miserable things which our correspondent speaks of. Such are produced by an undue excitement in winter, and the discontinuance of water before the foliage is properly matured, and the latter is so much preyed on by red spider as to form imperfect roots, resulting in weak growths in the following season.—G. A.]

THE CHASSELAS VIBERT GRAPE.

THIS Grape requires to be well grown, and then few can beat it. It ripens early, and the berries are very large, round, and of an amber colour, and the flavour that of the Sweetwater. I have twice carried off prizes at the Crystal Palace with this Grape, the first year a first prize, and the following year a second. The roof of my orchard-house (2400 square feet), has been for some time covered with the finest ripe Grapes; the rods were introduced into the house about the end of April, the Peaches and Nectarines having been sufficiently forwarded by heat, so as not to be injured by the shade of the Vines; forty-eight dozen of Peaches and Nectarines were gathered in one day, and the flavour was excellent.—A CONSTANT READER.

LARGE CUCUMBER CROP.—It is estimated by men who have facilities for ascertaining the truth that there have been salted this year in West Chester County not less than 100,000,000 of Cucumbers. Besides this, some producers have sent their entire crops to the city, right from the field. We know that a great many tons of Cucumbers have

been sent down on the New Haven, Harlem and Hudson River Roads, and many by boats, so that we do not think we are over-estimating the production of Cucumbers this year in West Chester Co., New York, at 130,000,000, or 1,300,000 dols., cash value.—(American Tribune.)

HOW MY PRIZE HYACINTHS WERE GROWN.

It may seem presumptuous for an amateur of not many years standing to lecture the whole gardening community on the cultivation and management of the Hyacinth; but as my flowers have been more than once prizetakers, I am about to commit the results of my experience to paper. Great numbers can only be well grown by nurserymen who grow them not only for general decorative purposes but for sale. The better way, in my opinion, is to make a selection of sorts that turn out invariably good, and grow two or three of each. Competitors, if they wish to have uniform stands of choice spikes, must grow a few of each sort. When I first began cultivating them I did very many foolish things, which told much against the production of fine spikes, but fortunately I was much easier satisfied then than now, and I persevered, and with a degree of success which I never anticipated. In my eagerness to have finely developed flower-spikes and flowers, I sought information from the most trustworthy sources. I read up all the articles that I could find bearing upon their cultivation, and what with feeling my way, and using a little common sense, I overcame many of the little difficulties that first prevented my success. I thought at first that large pots and very rich compost were absolutely necessary, and having furnished these things I watered the soil very freely—having reasoned within my own mind that, as they sometimes were grown in water alone (in glasses), the earth must be saturated upon the same plan. As a matter of course, I lost a few altogether, and the remainder only languished out a miserable existence, producing mere abortions of flower-spikes, and ill-coloured, substanceless flowers. A little more reflection might have taught me differently, but it is astonishing how very foolish and unpractical many people are who have their business engrossing their attention all day, and little time left for indulging in any favourite whim. I was considerably mortified at seeing such a grand array of well-managed flowers at the shows in Glasgow and Edinburgh, and determined, there and then, to state exactly how I had treated my bulbs to one or two good gardeners that I knew, and solicit their advice for future treatment. As doctors differ in their prescriptions so do gardeners seemingly; for one advised me one thing and another another thing; and although both modes might be productive of equally good effects, their conflicting opinions had rather a tendency to confuse me. However, I managed to get hold of some fine yellow turf loam full of vegetable fibre; and out of that heap, which I have carefully preserved under a wooden shed, I grow my prize Hyacinths. I introduced a little river sand, and a very little pigeon dung, the ammonia from which imparts a beautiful dark green to the foliage. I use seven-inch pots with wide holes at bottom, so that strong-growing sorts may have an extra benefit in the potfuls of soil. I plunge them, preparatory to their removal to a fine low-built pit I have for preserving a few choice things over winter. I bury the bulb all but out of sight in the pot when planting, I then place the pots in a two-light frame within 18 inches or 2 feet of the glass, and take care to have all my sorts placed together, the larger bulbs at the back, and the smaller ones at the front, so that I may see at a glance how they grow. Just now they are all in such a place; and from the state of the roots when planted. I have great hopes of coming in among the winning competitors next season. I give no air or ventilation for the first two months; but as soon as the crowns begin to get properly developed, I admit it freely on fine sunny days. I only take up a few of the worst for forcing, reserving the greater portion of my stock for the two grand field days in the east and in the west. I study the time for having the flowers fully open by the middle of March, and by adopting the cold-frame treatment, and taking them afterwards into my pit at the beginning of February, they neither require retarding nor forcing to have them in time for the days appointed for the great shows. I find that it is a bad plan for a competitor to

have to retard his spikes, as the foliage gets lengthy, and what professional gardeners call drawn, which tells very much against a show of otherwise good flowers. To force them is much better, but the best of all treatment in my experience is to allow them their own way. Do you know I cannot dress my spikes as I see some done, and I am a little put out about it; for doubtless a fine pyramidal spike with flowers looking you straight in the face, and regularly placed all round is what is most admired. I wish some of your able correspondents would advise me in this particular, I like to attend to and master everything I take in hand.

My frame is now filled with

4 Lord Wellington.	4 Charles Dickens.
3 General Havelock.	3 Laurens Koster.
4 Prince Albert.	3 Van Speyk.
2 Mimosa.	2 Bloksberg.
2 Général Peissier.	3 Grandeur à Merveille.
3 Alba Superbissima.	4 Macaulay.
4 Orondates,	3 General Cavaignac.
2 Mont Blanc.	2 Mrs. B. Stowe.
2 Snowball.	2 Monsieur d'Faesch.
1 Queen of the Netherlands,	4 Von Schiller.
1 La Tour d'Auvergne (forcing).	2 Koh-i-Noor.
2 Madame Van der Hoop.	3 Canning.

—“ALIQUI.”—(West of Scotland Horticultural Magazine.)

CULTIVATION OF THE MELON.

(Continued from page 293.)

MELONS IN HOUSES.

IN houses the Melon requires the same conditions of soil, temperature, moisture, &c., though different in their application, and that difference I will now dispose of.

Presuming that there is not a hotbed constantly at work, there should be provided a small box, 3 feet by 2 feet, and about 1 foot deep, after the manner of a garden frame, and this placed on a foot of rubble over a hot-water pipe, and as near the glass as practicable, will form an excellent place to raise seedlings. The frame should, of course, have a glass covering, and if in making it little wood is employed in proportion to the glass it could not be made better; for young plants, especially young Melons, cannot have too much light. The glass covering should either be moveable, or fixed on hinges, so that it can be raised at will for the purpose of admitting air, or examining the plants. The rubble may be covered with 6 inches of tan, in which to plunge the pots, and this should be heated sufficiently to afford a bottom heat of 85°, and a top heat of from 70° to 80°. These conditions having been secured, the seeds should be sown singly in 60-sized pots in the compost already mentioned, which should be in a moderately dry condition, as if wet the seeds are apt to rot instead of germinating, especially if old seed is sown. A certain degree of moisture is necessary to germination; the soil should therefore be moist, but not soddened with water. The seeds should be covered about a quarter of an inch deep, and if the soil be moist no water will be needed at the time of sowing. Shut the frame closely, and keep it so until the plants appear; this they will do in a week, or less. When the cotyledons or seed leaves appear admit a little air, and give some water if necessary, but not too much, or the plants will damp off at the surface. Be very careful not to let the plants become drawn at this stage; any symptoms of this are to be immediately checked by tilting the light more, and if this does not effect the object, remove it altogether. When the plants show their rough leaves pot them in 24's, sufficiently low that the stem may be covered with soil to within an inch of the seed leaves. The soil for potting should be placed within the frame for forty-eight hours, in order that it may be of the same temperature as that in which the plants were previously. Give water sparingly, but whenever necessary, and then at the same temperature as the frame hotbed, which should now be from 80° to 85°. The plunging material should be kept moist, and the evaporation from it will be sufficient for the foliage at this early stage.

After two rough leaves have been made it must be decided whether the plants are wanted with a stem or not. If the trellis on which they are to be trained is within a few inches of the soil in which they are soon to be planted no

stem is necessary; the leading point is therefore pinched out; but if a foot or more above it, the leading shoot must then be allowed to grow, removing, by rubbing off close, the side shoots formed along its stem until the required height is reached, when it should be stopped. This should not, however, be done until the plant is turned out, and not then if the trellis is 6 feet or more in width. If the vines are to be trained on the soil the plants should be stopped at the second rough leaf, and be treated in respect to training precisely the same as Melons in dung-frames.

When the plants are potted, the house in which they are to be planted should be made ready for their reception. The walls should be thoroughly washed with lime, mixing a pound of sulphur with each gallon of lime wash. If the old soil is not yet removed, it must all be taken away, and replaced with fresh, but only sufficient to raise at the place of planting a hillock of the required height. In putting on the soil it is necessary to see that the rubble over the pipes, tanks, &c., is not choked with soil, and if this is the case it must be riddled to free it of the dirt. The depth of rubble over hot-water pipes should in no case be less than 6 inches, whilst an inch will do over tanks. To prevent the rubble becoming choked with soil, a layer of turf an inch thick (charred to free it of wireworms) will be of service. On this place about 3 inches of soil, and then the hills may be raised in their proper positions, which will be, as a matter of course, at the lowest part of the trellis. The soil should not be wet, neither should it be dry, but healthfully moist. The house by the time of planting-out should have a temperature of from 70° to 75°, without sun heat, and the temperature of the soil should not be less than 80° or 85° at bottom, and 80° within the hillock. This should be double the size of those usually placed in frames on dung hotbeds, and the depth of cavity for soil must be equal to 1 foot for each foot of trellis to be covered. Borders of soil, however, 3 feet wide and 1 foot deep, will support plants covering a trellis 6 feet wide, by surface-dressings of manure. This being done the house should be sprinkled with water so as to create a moist atmosphere, and it is well to admit air, and shut up for a few days prior to planting-out, so as to have a sweet and pure atmosphere. It is well, too, if the woodwork need painting, to have this done whilst the house or pit is empty, and all needful repairs should be done at the same time.

These conditions secured the plants should be planted when they are of sufficient size to reach the trellis. The distance apart is dependant on the width of the trellis. If it is 4 feet wide put one plant under each light, but if 5 feet wide let them be 2½ feet apart, whilst for a six-feet trellis they should be 2 feet apart. The trellis should be near the glass, the most suitable distance, in my opinion, is 8 or 9 inches. If nearer the leaves are liable to be scorched, especially when wet, and spotted in consequence, and if at a greater distance they invariably have long foot-stalks, which are very undesirable. After planting give a gentle watering, and maintain a night temperature of 70°, with a rise of 5° or 10° without sun, but of 10°, 15°, or even 20°, with sun, admitting air at 80°, and shutting up early with the thermometer at 85°. Every available surface should be sprinkled with water of the same temperature as the house, between 8 and 9 A.M., and again at shutting-up, at 3 or 4 P.M.

At planting the vines should be tied loosely to the trellis at their proper distances apart—that is, if planted 3 feet apart, there should be three shoots 1 foot apart; if at 2½ feet a like number at as nearly equal distances as possible; if 2 feet, two shoots, which we obtain by stopping; and if the trellis is 6 feet or more in width, we have but one shoot per plant. Whether there be one or more shoots retained to train in at a foot apart (and these should be the strongest, and the trellis close to the ground), we do not stop the shoots, but rub out all besides them, and train to the upper side of the trellis, keeping them well tied down, but leaving sufficient room in tying to allow of the shoots growing. These are allowed to advance without stopping, until they reach to within 6 inches of the width of the trellis. The point of each is then taken out, and we have laterals already emitted at the base, more to come at the top, and the lower ones to be rendered more vigorous by stopping the leading shoot. These laterals will proceed right and left of the main shoot or stem, as we will now term it, and on them the fruit is expected to appear at the second or

third joint. If so, we stop it when the flower is sufficiently expanded for impregnation, twenty-four hours after which we take out the point of the shoot one joint above the fruit. In consequence of this stopping the sap, instead of finding its way into the growing point, will be directed into the leaf, at the axil of which is the fruit, and it will hasten swelling, or speedily cause the protrusion of another shoot, just as the fruit is set or not. If the fruit swell well, and we have two on a plant, every shoot is kept stopped close to one joint, and some of the weakest laterals are removed, encouraging any shoot, however, that may come above or from the same point with the fruit; for we want to draw the sap from the other parts of the plant towards the fruit, its size being dependant on the sap elaborated in the leaves above and by it.

The fruit being set every encouragement is given to insure its swelling by keeping the foliage healthy and stopping the laterals, which should be kept thinned out so as to prevent the principal leaves being unduly crowded, and deprived of light and air. After the fruit is set the new growths should not be allowed to make much way, for every inch of new growth diminishes the size and deteriorates the quality of the fruit; at the same time it is important to keep up a healthy root-action, and this can only be done by promoting growth to a certain extent. The young shoots must, therefore, be stopped by taking out the points, never allowing more than two joints above the last stopping after the fruit is set. The plants, to do them justice, should be gone over at least once a week, stopping new growths, thinning out those which are weak and ill placed, and regulating those left so that every part may receive its due share of light and air. It is all-important to tie up such shoots as require it before they become twisted by hanging down or grow out of place, for no amount of tying afterwards will compensate for a broken twisted stem. It is a very common but a very bad practice to allow Melons to completely cover the trellis before any pruning is thought of, and then it is given with great severity, and the consequences to the plant are bad. I say it is the worst of systems to allow a Melon, after setting its fruit, to grow, without stopping and thinning the shoots at intervals of not more than a week, until the shoots become entangled and the leaves are struggling to gain a due share of light. It is usual in this state of things to thin out the shoots, shortening those left to a few joints from whence they proceed, doing the same work then that ought to have been done ten days or a fortnight previously. Direful are the consequences. The balance between the roots and the leaves is gone. The roots take up the food from the earth, but the leaves left are imperfectly formed through the lack of light, air, and room to expand, and are unable to assimilate the food absorbed, or do so in an imperfect manner. In a few days a gummy exudation takes place from the cut parts, and they very often split open; besides, all along the stem a jelly-like exudation takes place, especially if the atmosphere is at all moist, and the consequence of this again is a diseased state of the plant. It was expected, no doubt, that the removal would cause a greater amount of nutriment to be thrown into the fruit. Never was a more mistaken notion. The leaves are the true source of the increase of the size of the fruit, and this depends on the assimilation of the food absorbed, and not on that actually taken up by the roots; for, no matter what may be the amount of food collected by the spongioles, unless there be a corresponding amount of the organs necessary for its assimilation, the fruit will not swell the more but remain at a standstill. The leaves formed in a crowded state of the plant are imperfect through the absence of light and air, and being suddenly exposed to increased light are incapable of bearing the change, they therefore become yellow-spotted, and unable to perform their ordinary functions and elaborate the greater amount of food impelled into them in consequence of the removal of the young growths in so wholesale a manner. In brief, the foliage assumes a sickly hue, falls a prey to red spider, new growths are put forth tardily and are weak, the fruit does not swell, but its rind is rendered hard as flint, and the plant is all over wounds and sores. In a short time there is a reaction, growth recommences, and the fruit is expected to swell. Perhaps it has begun to net; it would ripen if the growths were kept down, but it is small and it may yet swell. Swell, it does, but its rind is

incapable of expanding, and it bursts through the pressure from within.

All stopping and thinning of the shoots after the fruit is set should be confined to stopping the young shoots as they present themselves to one, or at most two leaves, and removing such shoots as have a tendency to deprive the principal leaves of their due share of light and air; but this must be done proportionately with the increased growth in another part.

After the fruit becomes fully netted all over, all growths whatever should be stopped to one joint, and the shoots gradually reduced in number in order to admit more light to the leaves and to bring the plant into a state of maturity, which is necessary to obtain full-flavoured fruit. Second crops from plants in houses are not worth trying for; therefore, a matured state of the plant is desirable by the time the fruit is nearly ripe.

If the first laterals or side-shoots do not show fruit, or if they do and it fail to set, these shoots, being stopped two joints above the embryo fruit, will push sub-laterals, most of which will show fruit; but before this every other lateral or side shoot must be removed, and this gives increased room for the development of the new parts. We may then reasonably calculate on the appearance of three or more embryo fruits from each lateral, and the sub-laterals should be stopped at one joint above the fruit. Duly impregnated it is hardly possible but that more fruit by half will be set than are really required. After the fruit begin to swell, two of the most promising on each plant are retained, and a number of the sub-laterals may be removed and new growths stopped, taking off more sub-laterals, providing always new growths are made to keep up the balance between the roots and leaves. It is best, however, when the growths are few and the parts already formed which have to be removed distant, for such a state shows that the plant has all its vital forces concentrated on the perfection of its fruit.

Should neither the laterals nor sub-laterals show fruit, which rarely happens under fair management, the old laterals may be cut clean out provided there be young shoots formed near the stem to take their place, when they are to be treated in the same manner as their predecessors. If there is not a sufficiency of young shoots to take the place of the barren laterals, a shoot may be trained from the base of the principal shoot, and the old shoot ultimately cut away to make way for the young one. Such will fruit most freely, but the fruit produced will not be equal to that furnished by a more vigorous plant.

When the fruit begins to swell it will need supporting, which I prefer doing by fastening a string of bast to the trellis and bringing it under the neck of the fruit so as to afford support and room for swelling, fastening the other end to the trellis. This will be sufficient until the fruit approaches maturity, when a strip of matting may be strung round the fruit, fastening it so that the latter cannot by any possibility fall on the ground, should it be allowed to remain on the plant until dead ripe, when it would throw itself off like a Peach. I consider the fruit is best cut a day or two after it commences to give forth its perfume, cutting it with a part of the foot-stalk attached. Such will keep much longer than fruit allowed to remain on the plant until dead ripe, and I fancy they are a trifle higher-flavoured, though not so highly perfumed. There are many methods of supporting the fruit of Melons, but none are equal to the ordinary tying process.

(To be continued.)

G. ABBEY.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

RENANTHERA LOWII (Mr. Low's Renanthera).—*Nat. ord.*, Orchidaceæ. *Linn.*, *Gynandria Diandria*. Native of Borneo. This gigantic Orchid has the unique peculiarity of producing "two entirely distinct forms of flower on the same spike." The lowest pair of flowers in each spike are uniformly tawny yellow, dotted with crimson; the remainder are pale green, blotched with reddish brown.—(*Botanical Magazine*, t. 5475.)

MASDEVALLIA CIVILIS (Tufted Masdevallia).—*Nat. ord.*, Orchidaceæ. *Linn.*, *Gynandria Monandria*. Native of Peru.

Stems grow in a tuft with, at the base, yellow flowers, spotted internally with purple.—(*Ibid.*, t. 5476.)

AQUILEGIA CERULEA (Long-spurred Californian Columbine).—*Nat. ord.*, Ranunculaceæ. *Linn.*, Polyandria Pentagynia. Native of the Rocky Mountains, California. Calyx blue, corolla white.—(*Ibid.*, t. 5477.)

MIMULUS LUTEUS var. CUPREA (Copper-coloured Yellow Monkey-Flower).—*Nat. ord.*, Scrophulariaceæ. *Linn.*, Didynamia Angiospermia. Introduced by Messrs. Veitch from the Chilian Andes.—(*Ibid.*, t. 5478.)

VITIS MACROPUS (Gouty-stemmed Vine).—*Nat. ord.*, Ampelidæ. *Linn.*, Tetrandra Monogynia. Native of South Bengal.—(*Ibid.*, t. 5479.)

ACHIMENES ROLLISONII.—It is a cross between *A. gloxiniflora*, and *A. Shearrii*, raised by Messrs. Rollisson, Tooting Nursery. Colour purplish lavender, throat yellow spotted with purplish crimson.—(*Floral Magazine*, pl. 217.)

SWEET WILLIAM.—Two "Auricula-eyed" varieties raised by Mr. Hale, Stoke Pogis, near Slough.—(*Ibid.*, pl. 218.)

IRESINE HERBSTII.—Introduced by Mr. Herbst from Brazil. It is from 12 to 18 inches high. Stem and branches a beautiful, almost transparent carmine, leaves purplish crimson underneath, dark maroon on upper side, with its numerous ribs carmine.

"The plant coming both from Peru and the River Plate will no doubt stand our climate better than the Coleus, and I may add, that in my nursery-ground, in close vicinity to and almost on a level with the Thames, open to all winds and weathers, without trees or protecting walls, it stood uninjured the slight frost which occurred in August last, while the leaves of *Coleus Verschaffeltii* were entirely spoiled, and those of *C. nigricans* dropped off. I am persuaded that the *Iresine* will maintain a first place in every collection where plants are grown for decorative purposes, and I am informed that it will be largely planted next season in some of the most celebrated metropolitan gardens."—(*Ibid.*, pl. 219.)

RHODODENDRON, *Princess Helena*, raised by Messrs. Veitch and Son, Chelsea, from *R. jasminiflorum*, crossed by a scarlet species imported by them, but not sent out. Tubes of flowers very long, and the whole a delicate pink.—(*Ibid.*, pl. 220.)

PEAR, Vicar of Winkfield.—About 1760 this was found growing wild by M. Leroy, curé of Villiers, in Brenne, France. He propagated it, and it was soon dispersed through its native country under no less than sixteen different names, such as Monsieur le Curé, Gros allongée, &c.

"Judging from the number of instances in which I have specimens of this Pear sent me to be named, it is one that though very generally distributed is very little known. Though not a Pear of first-rate excellence as a dessert fruit, still it is one which on account of its handsome appearance deserves to be cultivated in every collection of any extent where the soil is deep, loamy, and warm. According as the soil is more or less so, will the fruit possess more or less merit; while it is sometimes a melting Pear of excellent quality, at others it is only fit for stewing.

"The fruit has a powerful musky scent when ripe, and is of the largest size. It is long, pyriform, and often one-sided; but the most distinguishing characteristic is, that the eye is not in a line with the axis, as in other Pears, but is frequently placed on one side, and generally on the side opposite to that on which the stalk is inserted; by this peculiarity alone this Pear may be identified. The skin is smooth, green at first but changing as it ripens to yellow, with a faint brownish tinge next the sun, and strewed with numerous grey, russet, and green dots. Eye small and open with long, spreading, leaf-like segments, placed either on a level with the surface, or set in a very shallow basin. Stalk from 1 to 1½ inch long, slender, and obliquely attached without depression, and frequently with a fleshy swelling at its base. Flesh white, juicy, melting, and sweet when grown in a warm situation, but only half-melting and coarse-grained under ordinary circumstances. When it does not ripen it is a very excellent stewing Pear. It is in use from November till January.

"This Pear derived the name by which it is known in England from having been introduced from France by the Rev. W. L. Rham, of Winkfield, Berkshire."—(*Florist and Pomologist*, iii., p. 241.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Artichokes, *Globe*, they should have a little loose litter laid round them for protection, more particularly as the continued mild weather induces them to grow more than is desirable at this season. *Asparagus*, take up roots for successive forcing, and if new beds are to be made now is the time to see about making them ready for spring planting. *Cabbages*, stir the surface of the soil amongst them, and also Lettuces in the open quarters, and give occasional dustings with lime. *Endive*, lay slates upon the plants, and cover up with leaves on the approach of frost. Do not forget to look over Endive and Lettuce in store, and remove all decaying matter. *Peas*, the beginning of the week will in most localities be a good time to make a moderate sowing of these, and also of Broad Beans. *Sea-kale*, cover up a succession, taking care to force very gently. Any plants not at present required for forcing should have the crowns covered with light dry soil, and then with partly decomposed leaves.

FRUIT GARDEN.

Planting young fruit trees, and transplanting or raising those of larger growth, must be vigorously prosecuted. The season is very favourable, and the earlier these operations are completed the greater is the chance of success. With all newly-planted fruit trees or shrubs mulching or top-dressing is of immense utility in shutting in, or rather arresting the departure of the remaining ground heat of the past summer, and imparting nutriment to the soil for the ensuing year. It ought to be well considered that the soil will gain no heat between this period and the end of February, but, on the contrary, a progressive loss must ensue for the next two months at least, unless we resort to the process of mulching. This proceeding is, we think, indispensable as connected with early autumn planting, whilst for Vine-borders, whether the Vines are intended to be forced early, or are bearing very late Grapes, the practice is equally necessary and important.

FLOWER GARDEN.

Alterations, planting, &c., will be carried out this autumn with much comfort as far as the weather is concerned; and those who have employed additional labour in these operations will have little to regret in the spring. All tender or half-hardy shrubs should have some protection planned forthwith, and especially the tender kinds of Roses. Standards of the latter may have a bunch of dry moss, or a wisp of hay or straw, or some dried fern, bound round the head, and the whole well fastened to a stake. Also get the stock of Briars for budding upon next year without delay, for unless they are planted before spring, they seldom furnish strong shoots for early budding. Many object to planting shrubs and trees in winter, believing that the roots if hurt at that season are liable to rot, and certainly early in the autumn is a much preferable period; but with weather like the present we would not delay such work a single day; and if the soil is properly prepared by draining, &c., where necessary, as should always be done before planting, there will be fewer failures from planting now than if the work were postponed to March. When, however, the ground to be planted is of a clayey nature, and in an unkind state at present, it will undoubtedly be better to defer planting until spring, meantime using every means to improve the state of the ground. Soils of this nature should always be dug or trenched some considerable time before planting, as neither drainage, nor anything but exposure to the action of the atmosphere, will bring them into a fit state for planting.

FORCING-PIT.

Dutch bulbs should be largely used for forcing at this season, and where hardy shrubs are being forced for the decoration of the conservatory, they should be brought into flower as soon as circumstances admit. Do not forget to introduce into gentle heat by degrees a good batch of Roses, choosing the most promising plants of Teas, Bourbons, and Hybrid Perpetuals, which are the best kinds for winter flowering. A gentle bottom heat will be of service to these, as also to most other plants subjected to heat, in order to make them flower early, and a moist state of the atmosphere must be secured, admitting a little air on every favourable opportunity. Double Roman Narcissus, Crocuses, Neapolitan Violets, Mignonette, and Cyclamens bloom early without

much forcing. Fire heat should be applied principally by day; the pit to be shut up early and night heat applied very cautiously indeed at this season. Apply frequent but very moderate fumigations of tobacco to destroy the green fly.

GREENHOUSE AND CONSERVATORY.

Damp or insects do irreparable injury to softwooded plants at this season, and these must be carefully attended to if they are to be wintered in first-rate order. Pelargoniums to be kept rather dry and cool, giving whatever water may be necessary in the mornings of fine days, so that the superfluous moisture may be removed before the evening, avoiding the use of fire heat except when necessary to prevent the temperature falling below 40°, or to dispel damp. Every decaying leaf to be instantly removed, and drip must be studiously avoided in these houses. Herbaceous Calceolarias require very similar treatment, except that they are very subject to the attacks of thrips unless afforded a moist atmosphere; they must, therefore, be narrowly watched and smoked lightly two or three evenings successively if this pest makes its appearance, keeping the atmosphere moist, and giving air on every favourable opportunity to prevent the foliage from flagging. Cinerarias for late blooming to be kept cool and airy, and not be allowed to suffer for want of pot room. These must not be trusted in cold pits after this season, for they cannot endure much frost. Hardly anything can be worse for the development of a healthy vigorous habit in plants than subjecting them to a high temperature at the present season, when light, so important to the healthy action of vegetable life, cannot accompany it.

PITS AND FRAMES.

Abundance of air to be continued as long as possible, avoiding, however, the least wet. As long as the weather remains mild and the thermometer can be maintained above 32°, give air night as well as day.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Cauliflower.—Took up a few nice plants with balls from a border, and placed them in seven-inch pots in the orchard-house, with the hope of obtaining some early spring produce from them, as however good Broccoli may be at that time, it rarely equals the Cauliflower in delicacy of flavour.

Shallots and Garlic.—Planted, digging the ground nicely, levelling it, drawing drills a foot apart and about 1 inch deep, then firming the little bulbs, from dividing the larger ones, about 2 inches apart, and then scattering over them some charred rubbish. If the ground is very stiff, it is best to plant them still more shallow, for as soon as they begin to root they will firm themselves sufficiently. Before that time the charred rubbish and soot and lime will prevent the worms taking them out of the ground, and will also help to prevent the frost doing the same. One advantage of October planting is, that the plants are established before winter. We have rarely known the hardest frost injure these plants when well established. A few bulbs may be left for planting in February or March.

Onions.—Looked over the stored ones in a wet day, and found more giving way than we should have expected after such a dry season. Those roped are keeping much the best, hardly one showing any sign of rottenness. Hoed amongst the young crops in the open air, to keep the surface open and rough.

Digging and Trenching.—Of this we have been able as yet to do little, but the sooner the ground is prepared for early Peas and Beans, and for fresh plantations of Asparagus, Rhubarb, and Sea-kale, the better will the plants succeed. We now seldom sow Peas and Beans in the autumn, but the results of many years' experience, convinced us that from the 18th to the 25th of this month is soon enough to sow, as if sown earlier they were less able to withstand the frosts of winter and spring. In this respect there is often a great difference as respects hardiness between the young of vegetables and the young of animals, the latter being so easily injured, whilst the young seedlings of the former will stand often much harder treatment than older plants. For years, too, when our crop was sown on ground running from north to south, as on a south border, we used to throw the ground

into sloping banks 4 feet apart, and running from north-east to south-west, and sow the Peas about the middle of the sloping bank on the west side. The crest of the ridge, and a row of evergreen branches on the north side, did much to shelter the young crop.

Asparagus.—The ground for this should be deeply drained, or well broken up even into the subsoil. Where much Asparagus is wanted for forcing, an old-fashioned plan has never yet been improved upon. A large wide trench is dug out in winter—say 5 or 6 feet in width, and some 3 feet in depth, into this trench all prunings and hard rubbish are thrown in spring to the depth of 18 inches or 2 feet. Upon this, in May, some 18 inches of littery dung is placed to form a slight hotbed beneath; the soil is then used for growing ridge Cucumbers and Vegetable Marrows in summer, and when that crop is gone the ground and the dung are well mixed and turned over in winter, and then on this raised bed the Asparagus is planted as soon as it is 2 inches or so in height. This mode is best suited for heavy soil. Another good plan is to drain, or at least stir up and leave the subsoil; trench well for 30 inches deep, mixing manure all through, but keep the most and best decayed for the surface spit; turn that frequently, and finally turn up into little ridges from 26 to 30 inches apart. Plant on the top of these ridges, and give mulchings of rich manure during the summer. This is one of the simplest modes of producing good Asparagus easily, and in some respects it is more suitable for small gardens than beds. Asparagus may be planted at any time, but it is always best to do so when the young tops are about 2 inches above ground in spring, taking care that the roots do not become dried. Plants from one to two years old are better than older ones for planting. We have made preparations, by a slight hotbed, for taking up some Asparagus for forcing, but we have not done so as yet, as we dipped rather deep into our Asparagus reserves last season, and did not plant so much as we ought to have done. Other vegetables much the same as last week, with the exception of taking up some Sea-kale and Rhubarb ready to be placed in the Mushroom-house. Those who force these out of doors, should cover the ground now with litter, leaves, or clearings from the flower garden. A very thin covering of tree leaves—say from 12 to 15 inches, will give an early cutting of these vegetables if put on in time, so as to keep the summer heat in the ground. The less rank dung is used the better, as it always less or more injures the flavour, and if not often examined it is apt to draw out and spindle the heads, and then they have a lanky appearance at table.

FRUIT GARDEN.

Much the same as in previous weeks. Looked over stored fruit, and nipped a few berries from late Grapes inclined to damp in this muggy weather. Any root-pruning, replanting, or planting of fruit trees, should now be set about in all suitable weather.

ORNAMENTAL DEPARTMENT.

The rains having now come, all planting, replanting, and moving of deciduous plants and evergreens may now be proceeded with where water can be given. Where that is still scarce and the soil remains dry, it will be a good plan to open the holes and have the soil spread out round them. It will thus be damped by some showers, and be in a good state to go round the roots, so as to set them growing afresh at once without watering. In general at this season the soil is wet enough; but at a couple of inches or so from the surface in this neighbourhood, it is still too dry for successful planting without watering.

Lawns and Flower-beds.—The summer beauty is now gone, and what was once so pleasing is now becoming offensive to sight and smell. The produce of the beds placed in a large heap will yield a nice fermenting heap for many purposes. Hollyhock stems we will most likely burn or char. The lawns have been gone over with the scythe before brushing them up, so as to clear them of leaves, at least in all places where the leaves have fallen; and where, as in the case of the Oaks, these have not yet fallen or have left a good share behind, the clearing-up has been mostly confined to the walks. This work has met with some interruptions owing to other jobs and the state of the weather, as it is unavoidable to do such clearing-up when the wet would leave a dirty earthy appearance on the green grass. One of these

jobs has resulted from the cutting down of a number of trees close to the mansion and offices, which a few years ago would have been considered as an act of wanton destruction; but even in exposed places now the importance of air and sunlight round a dwelling is considered of more value than shelter accompanied by shade. The spray and the faggots from such cutting will give us a good supply of little pieces for lighting fires near at hand; and it is always advisable to have a number of these tied up and stored in a dry place ready for use. Where Willows are plentiful they are capital for tying them with. We generally use a little band of wheat straw. Say eight straws or so are laid down; a small handful of shavings, or straw, or stubble laid on it; and a good handful, say 6 inches through and 15 inches long, of the chopped twigs and branches, over which the two ends of the straw are brought, twisted round and stuck underneath the band; and with one of these nice and dry a fire may be very quickly set going in a furnace. This work is best done in a fine day in the open air, but we generally defer it to a wet day, as Friday proved itself to be. For the same reason, having been very busy with various other matters, the same wet day that set us away from the lawns and beds furnished a good opportunity of looking over a lot of

Scarlet Geraniums in the sheds. Some of these that we wished for centres of pyramids next season we stripped of all their leaves larger than a florin piece and many of the smaller shoots, and potted separately in four and five-inch pots, retaining the plants at their full length. The great proportion, however, we cut over some 6 or 8 inches from the collar, stripped off all the leaves, shortened any long roots, dipped the cut tops in lime and charcoal powder, and allowed the roots to stand some five minutes in chilled water, and then packed them closely in pots, boxes, or beds, say from twenty-five to thirty plants in a 12-inch pot, hanging well out round its sides, however, and set them beneath stages, or in beds, pits, or frames, &c.

One of the best lots of such Geraniums we ever had, as there was scarcely a miss in the shape of a dead plant among some 400, were thus managed: They were stripped as above stated, and then they were packed closely on the floor of a shed in soil neither wet nor dry. The shed had a window to the west, and a door that opened to the south. We made three beds in the shed, some 4 feet in width, with a two-feet path between them. The door and the window we opened in bright days and mild weather during the winter, but in dull foggy periods, and in frosty weather we kept all shut up, and in the latter case hung a mat inside the window. No frost under from 6° to 8° interfered with the interior of the shed; but when the temperature fell lower than that we spread a little hay over the beds of plants, and removed it as the weather became better. So managed these old plants, that bloomed splendidly the next season, cost little more trouble during the winter than roots of Dahlias and Potatoes would have done. We have as a general rule ceased to regard these as superior for our purposes to the small plants that we have struck and standing in boxes, and occupying from 1 to 1½ inch square each; but, then, each of these plants must be carefully attended to during winter with light, air, and watering, and must receive more room for potting and transplanting in spring, whilst these old plants require scarcely any attention all the winter through, except being protected from frost, and will keep alive though little light or air be given them as their portion. What was done in that shed may be done in any spare room, garret, stable, or dry cellar, only it would be advisable in all such cases to pack the plants in pots and boxes, firming the soil about them when it is in just a medium state being neither wet nor dry. If the roots are rather dry, instead of watering the soil to encourage damp, it would be much preferable to place a handful of such roots up to the collars of the plants for five minutes in chilled water. Unless the beds, pots, or boxes are dried by some artificial means, such plants will in general need no water until the fresh young leaves about the size of a sixpence are breaking all over them about March, and about April they will be in need of more room.

Some amateurs with very small parterres, plant out their Geraniums in pots, and in their case it would be the best plan to strip the plants of the foliage and pack them away in the pots—that is, supposing they had no glass to place them under. There will be enough of roots in the pots to

keep the plants slowly growing, and when turned out next season the roots that go beyond the pots will secure enough of luxuriance.

Plants grown in boxes outside the window during the summer will be still more easily kept in these boxes all the winter on the Harry Moore system. All that is necessary is to allow the soil to become rather dry, and place the box after the plants have been stripped of most of their foliage in an airy place, and where protection can be given in severe frosty weather.

Thousands of these showy Scarlets might thus be easily kept all over the country, and the cottager may make sure of them, as he does with a Dahlia or a Potato-root, if the frost is excluded, and the roots are neither over-damp nor kiln-dried, and the tops are neither skeletonised with fire heat, nor damped nor rotted by being placed in a continual fog. All things considered, no place is better than a hay-loft or a garret, where light and air can be given them in a bright warm day.

Calceolarias.—Finished putting in the last of our cuttings, or nearly the last, on Thursday, as we expect some novelties yet to come to us. We would have liked as well if all these had been in by the 1st of the month, but we could not well get at them, and we have no fears of their not being all right before March, if we can keep the frost from them. Such things rarely suffer from damp. A close atmosphere that would cover a Verbena with mildew, will just suit the hardier and moisture-loving Calceolarias. Having placed our *Amplexicaulis* cuttings in wooden boxes, we moved them from the cold pit, in a place where, if necessary, extra damp and frost can be excluded by a little dry heat, as they are not so hardy as the other shrubby kinds. Those who grow the herbaceous and semi-herbaceous kinds for show in April, May, and June, should see that the most forward have plenty of pot room, as if confined too much at the roots they will throw up the flower-stems prematurely.

Cold Pits and Frames.—A great proportion of our smaller plants, and cuttings striking of bedding plants, were under glass frames that had been used for various purposes during the summer, with less or more of a hotbed under them. These are about the worst receptacles we can have in dull, foggy, damp weather. If we use a frame for such protecting purposes, it is much better to place it on a raised platform of hard soil, so that all the moisture may run away from the sides and ends of the frame. When placed over an old bed the moisture soaks into it, and is sure to rise inside in the shape of thick vapour. That with foggy days combined, is almost sure to bring damp, at least in such cases as ours, where for economy of space we are under the necessity of placing the cuttings and young plants very thickly during the winter months. We went over the most tender of these, picking off any damped leaf, and set the pots on shelves in airy houses, where a little fire heat can be given, and by fresh surfacing the beds with dry coal ashes, the hardier plants left may be set a little thinner.

Lily of the Valley may now be taken up for forcing, and all hardy shrubs intended for forcing from Roses to Rhododendrons, will be all the finer if a bottom heat of from 70° to 80° can be given for a month before the top temperature is much advanced. Bulbs will have to be looked at, and mice kept from them, and those planted thickly out of doors in leaf mould may be lifted with their roots and balls and transferred to flower-beds, after these have been suitably prepared for them. The same will answer admirably for early flowering also in glasses, it being only necessary to take the ball of roots and earth in the two hands, wash them in a pail of water until nothing but the roots are left, place them carefully in the glass with a few bits of charcoal, and then fill with water.

Agapanthus in pots, which do so well with the bottom of the pots in water at the sides of a reservoir in summer, will stand very well all the winter in a dry shed, the pot plunged in, and just covered with litter or coal ashes, and so will all the varieties of the *Japan Lilies*. The *Lancifolium* group are just a little more tender, good pots of them will be kept nicely in a common cellar, as the damp of the floor will afford sufficient moisture until growth commences in spring, when the pots may be brought out, the drainage examined, and fresh surfacings of a rich compost given, which with manure waterings will render fresh potting often unnecessary.

Chrysanthemums, Cinerarias, and Primulas, will now require plenty of water, light, and air, and as the flowers of all of them show, a little weak manure water will be an advantage. Some Azaleas well set with buds may be placed in the forcing-pit, and Camellias now must never know drought. Hardwooded plants should be kept separate from the soft-wooded, and air given to them more carefully, taking care that in the case of Croweas, Boronias, and Chorozemas, though the house has plenty of sweet air, that the air in cold, damp days does not strike on the plants at once. Mignonette in pots, and especially if grown in the tree or the pyramidal style, should now be kept free from damp in a sweet atmosphere ranging from 43° to 50°. In this dull, foggy weather care should be taken not to spill a drop of water in a house, or use it where not wanted. Watering all overhead in such circumstances is just an act of barbarism.

—R. F.

COVENT GARDEN MARKET.—NOVEMBER 19.

Continental supplies, consisting of Apples, Pears, Medlars, &c., are very heavy, and home-grown fruit and vegetables are brought in abundance. Apples and Pears consist of the same kinds as noticed last week; Newtown Pippins are of very superior quality. Grapes are plentiful and good; of Pines there is a moderate supply, but sufficient for the demand; Peaches are over; Oranges from Gibraltar and Lisbon have come in, and prices rule lower. Owing to the open weather, Brussels Sprouts, Savoys, Cabbages, and Greens, of all kinds, are abundant. Of Potatoes the supply continues very heavy.

TRADE CATALOGUE RECEIVED.

W. Bull, King's Road, Chelsea, London.—Retail List of New, Beautiful, and Rare Plants.—1864-5.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

POTATOES (R. E. K.).—If you write to Captain W. W. Hornby, R.N., Knowsley Cottage, Prescot, we have no doubt that he would give you the information you require.

PORTING FERNS AND BEGONIAS (*A Ten-months Subscriber*).—The proper time to repot these is the middle of March. Keep the Begonias dry during the winter, and the Ferns rather dry at the root, but not so as to affect the foliage. Our "Fern Manual" contains full directions for the management of all kinds of Ferns.

WOOD versus IRON ESPALIERS (*W. D. B.*).—Iron either well painted or galvanised is much preferable to wood. There is no fear of rust if only the uprights and wires are kept properly painted. Espaliers are chiefly employed for Apples and Pears. What tree is it you wish to know the suitability of for espaliers?

WINTERING BEGONIAS AND FARFUGIUM (*B. Salterton*).—You are doing quite right to withhold water if you have no place to winter them in but a greenhouse; but if you have a house with a temperature of about 50°, and you give sufficient water to keep the foliage fresh, but not half so much in winter as in summer, your plants will flower most of the winter. On the other hand, if in a greenhouse, keep dry, free from damp and drip, and the plants will live with scarcely any water; but a little may be given now and then to prevent their drying up. The Farfugium should be kept dry, and be allowed a season of perfect rest by plunging the pots to the rim in coal ashes in a cold frame, where they will not require any water during the winter; or they may be wintered in a cold greenhouse, placing them in the coolest part, and not giving any water, except a little to prevent the soil becoming dust or very dry.

WINTERING HOLLYHOCKS (*Stultus*).—You may take up the roots and pot them, plunging the pots to the rim in coal ashes, and keeping as near the glass as possible; but it is quite late enough to do this kind of work. A mat or two placed on the lights in severe weather will be all the protection required. Give air on all favourable occasions. Another way is to draw a little earth towards the crowns of the plants, and place litter around them closely, but not so as to cover the young shoots. You may, however, strew a little dry litter over them in frosty weather, removing it when the frost is gone.

DESTROYING MEALY BUG (*Birmingham Subscriber*).—Yours is one of those perplexing questions that no one can answer satisfactorily, because it is not stated what plants are infested with the pest to be destroyed. If plants, boil a pound of strong shag tobacco in a gallon of soft water for an hour, and strain off the liquid. Dissolve a pound of gum arabic and a pound of soft soap, also a pound of flowers of sulphur, the two first in warm water, and then add the sulphur, so as to form a sort of paste. Put this mixture in a tub containing ten gallons of water, heated to a temperature of 140°, mixing the whole well. Keep stirred, so as not to allow of the ingredients settling, and when it has cooled to 130° or 125° for hard-leaved plants, as Pine Apples, and 120° for plants generally, dip the plants in it for about a minute, taking care to wet all the axils of the leaves and the stems. Let the plants stand until dry, and then repeat the operation. In forty-eight hours after the last dipping syringe with water only at a temperature of 120°.

KADANG (*C. & O.*).—It is usually spelt Cat-jang, and is the seed of the *Dolichos catiang*. It is of the size and firmness of a small Kidney Bean. Whether it would require decorticating before being pressed we cannot say, but we should think not. The seeds are not unlike Kidney Beans and vary in colour from black to pale brown.

VINERIES (*A Novice*).—If you try your experiment as to shading now you will be quite safe, if the shade of the second house rests only for a little on the front of the first house. No house should shade the other in the least in October or March. The higher you make your first house at back, and the steeper, the more room you will have. For summer use the houses may be flatter in the roof. For late Grapes to hang through the winter the roof should be as steep as for an early house. For early and late work, the section which you gave of a proposed house will do admirably. As to the commercial part of the matter, we would not like to take the responsibility of being an authority. Presuming that you have Vines 2 feet apart, and each yields 74 lbs.—no great weight certainly—still you must recollect that you would not get that for several years; and then there is the capital sunk in the houses, soil, draining, &c., besides what you would spend for fuel, and we think the labour will be much more than you expect.

GESNERAS SHEDDING THEIR FLOWERS (*C. W. P.*).—This is very prevalent when they bloom late. We think it is the result of some check that is given to the plants, either lack of sufficient heat, or a deficiency of water; but it is not certain what occasions this premature falling of the corolla. With us they bloom splendidly one year, and indifferently, though equal in promise, the next, and this under the same treatment and conditions of heat and moisture so far as we are able to determine. We are not, therefore, prepared to assign a reason for which troubles us as much as yourself. The JOURNAL OF HORTICULTURE, &c., may be had free by post from our office for 17s. 4d. for twelve months.

SEWAGE FOR VINE BORDER (*J. W. F.*).—We would not use the contents of the cesspools for mixing with the Vine-border. After being well exposed to the air a little of it may be used for top-dressing. You should have taken off your bedding-plant cuttings earlier. Geraniums and Verbenas in that state will be better both of top and bottom heat, say 55° to 60° of the former, and 75° to 85° of the latter, until struck, and then harden-off. Calceolarias will be better without any heat. If any is given let it be as much as will afford a bottom heat of from 60° to 65°, but no top heat; but they will do without very well, only give them time. The "Vine Manual" is 2s. 6d., and for 2d. additional you can have it free by post from our office.

LATE VINEY (*J. Stockport*).—With your large squares of glass we do not think that your proposed ventilation will be sufficient. Your most economical plan would be, in addition to the openings at each end, and opening the doors in the middle of the day, to have at least four ventilators at the apex of the roof, each 20 by 15 inches, say one 8 feet from each end, and the other two in the intervening space. These could slip in between the rafters and be pivot-hung, and only cost the frame which holds the square. We should think, under the circumstances, if the clay is very tenacious, that you will not overdrain. Does the water lie in the bed of clay, with the bed of sand underneath? if so, you might as well go to the sand at once, and in that case we should think the drains 18 feet apart would do. We have known such cases as yours, where the water would not remain in a five-feet bed of clay if the bed of sand, gravel, or chalk, beneath was at all hollow.

INSECTS (*M. Barbonne*).—The large fly you sent was not a wild bee, but one of the drone-like flies, *Helophilus Pratorum*. The other yellow one is *Scatophaga merdaria*.—W.

VINES UNFRUITFUL (*H. M.*).—If your Vines are at all strong we would let them alone and try them for another year, as you think the border is all right; but though you may thatch in winter, we would remove the loose slates from the border in summer. If they had been solidly bedded we might suppose they increased the heat, but being loose they would keep the border cool, and keep sun and air from it.

BEURRÉ DE RANCE PEAR (*W. Earley*).—This, before it is ripe, is an excellent stewing Pear; and so are others of our first-rate dessert Pears, such as the Beurré Diel, Easter Beurré, and Chaumont. Your fungus is Nidularia campanulata, usually found on wood shavings.

LINSEED OIL-CAKE AS A MANURE (*Norfolkensis*).—It is quite as good as Rape-cake as a manure, and we have known it successfully used by being trenched in and well-mixed with the soil beneath each drill in which Carrots were sown. This was not only to act as a manure, but to keep the wire-worms from the roots. We cannot help remarking, in connection with this, that "The Driffield and East Riding Pure Linseed Cake Company" is the only one of which we ever read of a shareholder saying that "If possible, its management gave the shareholders too great satisfaction." The testimony in favour of the purity of its oil-cake must gain the attention of all stock farmers.

HEATED FERN CASE (*Quite an Amateur*).—We employ the Bijou Plant Case made by Mr. Stocks, Cabinet Maker, Archer Street, Westbourne Grove. It is ornamental, heated by Child's night lights, and these, with a green baize cover for winter nights, we find preserve the tenderer Ferns effectively.

NAMES OF FRUIT (*O. M.*).—Pears.—6, Ne Plus Menris; 8, Bergamot Cadette; 9, Beurré Diel; 11, Marie Louise; 12, Beurré Bosc; 14, Easter Beurré; 15, Eyewood. Apples.—1, Russet Nonpareil; 2, Winter Greening; 5, Adams' Pearmain; 6, Gravenstein; 7, Winter Pearmain. (*J. F.*).—5, Winter Hawthorn; 6, Golden Pippin. (*R. H. A.*).—1, Swan's Egg; 2, Beurré Diel; 3, Fondante d'Autunne; 4, Bergamotte Cadette. Apple-Reinette du Canada. Where the numbers are not mentioned the fruit was unrecognised. (*A. R.*).—Your Pear seems to be the Red Doyenne. (*J. P. S. Wimbledon*).—1, Golden Reinettes; 2, Colonel Vaughan's.

NAMES OF PLANTS (*C. W. P.*).—Your Orchid flower was completely smashed in transit through the post, and we can make nothing of it. You must send another and better specimen, and tell us what kind of leaves the plant has. (*J. M.*).—The Saxifrages are too numerous for us to identify a species from a leaf, but we think it is Saxifraga cotyledon, called by some Botanists *S. pyramidalis*. (*A. Young Gardener, Goole*).—1, *Scopolendrium vulgare*; 2, *Pteris hastata*; 3, *Nephrolepis tuberosa*; 4, *Pteris tremula*; 5, *Adiantum capillus-Veneris*; 6, *Asplenium trichomanes*; 7, *Adiantum setulosum*; 8, *Pteris serrulata*. Many of the specimens were mere morsels. It is unreasonable to ask any one to identify plants from such fragments. (*G. B.*).—*Lastrea Filius-mas*; the small scrap *Lastrea dilatata*; the Moss *Dicranum glaucum*, White Fork Moss.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BRAHMA POOTRAS.

We suppose Dr. Johnson always prefaced his conversation with the word, "Sir." We can understand that "members" acquire a habit of doing so. We know that many vestrymen and common councilmen make it a practice to do so when they have occasion to speak. We had been reading the "Temple Bar Magazine," and looking at the title-page—"Sir," said Dr. Johnson, "let us take a walk down Fleet Street." We had a sort of inward chuckle, and we said to ourselves, Mr. Editor, Sir, let us walk through your last Number. "Brahma Pootras," by our "witty and able correspondent." We will make him attorney-general of Brahma Pootra, but we don't believe a word he says, so straight-way we set to work to demolish his arguments. Who has not seen in country churchyards the following epitaph?—

"Affliction sore, long time I bore,
Physician's aid was vain,
Till Heaven did please, my woes to cease,
And eased me of my pain."

Kingsley in his inimitable description of the school where all were over-taught, without reference to age or talent, has paraphrased it thus (or something like it)—

"Instruction sore, long time I bore,
And cramming was in vain,
Till Heav'n did please, my woes to ease,
With water on the brain."

Being the epitaph on one of the unfortunate scholars who had sunk under the effort to make him a partaker in all the advantages of modern education. So, considering our able correspondent was buried with the Brahmases, we thought we would try epitaph the third.

"In Brahma's cause he made a noise,
And fought throughout his days.
The J. or H. put him to rest,
And killed him with sham praise."

We wonder if he will ever write again about them. Is, or was, Dr. Bennett, M.D., or Mus. Doc., or LL.D., or (shade of Sydney Smith) D.D.? If he was the first, he treated the Brahmases and their origin as he would a patent medicine. What would be thought of the man who went to the pro-

prietors or inventors of Scott's Liver Pills, Holloway's Ointment, Barry Du Barry's Revalenta, or Thorley's Food for Cattle, and asked for the names and proportions of the different ingredients? Or suppose a man in Melbourne, the fortunate possessor of a nugget as large as a dustman's bell, what answer would he give to the passenger who inquired the exact spot where he found it? Mr. Bennett is brought up to the rescue, and his weight depends on the "evidence of his own senses." Well, it is clear our "able correspondent" is allowed no such latitude.

The mother of shows progresses deservedly, and every year the entries increase. This is, we think, most convincing proof the public approves the entire management of this great show. May its shadow never grow less.

"Y. B. A. Z." is a good, sound, common-sense writer, and if he be a maniac, there is method in his madness. That is a good idea of his, that the judge or judges is, or are, to give an account of their awards. Fancy the poor man the day after the show opens, meeting his constituents like a member of parliament, to render an account. We should like to be present.

Sir, we pray you excuse that we have used the first person plural, the editorial "we." We are no editor, but simply—Z. A. B. Y.

RAILWAY CHARGES FOR POULTRY.

I WISH, through the medium of your widely circulated Journal, to make known to intending exhibitors of poultry at Birmingham a recent alteration in the scale of charges by the Great Western and London and North Western Railway Companies, which will, if acted upon, seriously affect regular exhibitors; and at the same time I would solicit your influence in trying to obtain a remission of so unjust a charge. According to the new regulations, a printed copy of which I have this day seen, all live poultry will be charged according to the regular scale per pound for distance, and an additional fifty per cent. put on to the already sufficiently high charge. Now this is encouraging poultry shows with a vengeance.

How I came to know was, I sent a pen of Aylesbury Ducks to Worcester at the regular charge, and on return a demand of half as much more was made upon them. I remonstrated and made inquiry, and such is the result.—EDWARD SHAW, *Plas Wilmot, Oswestry*.

[We hope that the Committees of the Birmingham and other poultry shows will use their influence to have this extra charge rescinded. Directors of railways make the same mistake that the proprietors of periodicals make when they raise their price to compensate for a declining sale. Both would act more wisely if they increased their temptations to win customers. Directors of railways should remember that poultry shows increase the number of railway passengers.]

POULTRY JUDGES.

BEING from home, I have only just seen "A CORK FANCER'S" letter under the above heading in your Journal of the 8th inst. I should not have troubled you with any notice of it but for one or two misstatements which require contradiction. He states of the Judges whom the Cork Committee had appointed, "It so happened both of them were Judges approved of by the Poultry Club." This assertion I can only say is entirely without foundation, neither of the gentlemen ever having been even thought of as poultry judges by the Club, and only one of them as a Pigeon judge, though both are known to excel in this division.

As regards backing out of the matter, I fully intended still sending several entries; but as for promising the Club's assistance towards the expenses of the Judges, I was not in a position to do so, yet I undertook to bring it before the meeting at Birmingham.

As "A CORK FANCER" appears so totally ignorant of the Club and its constitution, I beg to inform him it is composed of gentlemen of quite equal standing to his Society, and who have only the advancement of poultry shows in view, and to obtain an uniformity of awards, and also do away with all partiality; and that they are quite as inca-

pable of his gross and most unjustifiable insinuations, which from his own reference refute themselves.

When the public learn the names of the Cork Judges they will be able to decide between us, whether they are the well-known poultry Judges at London, Glasgow, and Birmingham your correspondent would fain lead them to suppose, though gentlemen of the highest standing and integrity.

Before your correspondent again rushes into print, I would advise him to carefully examine his grounds before attacking either an individual or a fellow Society without just cause.

A suggestion it only was, though of an interested exhibitor, and when declined there was an end of it.—A STEWARD.

P.S.—Since writing the above I have received the Aberdeen schedule, which I perceive is again under the Poultry Club—a proof that its influence is of great benefit to it, and highly approved of in that quarter, since I find its prize list is greatly extended, and the addition of six silver cups this year.

POULTRY SHOWS NORTH AND SOUTH.

I AM glad to see that this subject, to which I alluded a few weeks ago, has been taken up by several correspondents, and although each writer differs slightly, yet I am glad to find all acknowledge that the Dorking fowl or fowls ought to have more prizes and more classes at all our southern, perhaps I ought to say south-eastern, Shows.

I agree with the remarks of a "WILTSHIRE RECTOR" with one exception, and that is the desirability of introducing the dark-legged, non-sitting breeds into our south-eastern district. He seems to forget that the colour of their legs is a fatal bar to them as marketable chickens; and as for eggs, our market is overdone with French and Belgian eggs, sent over by thousands to our south-eastern ports. Chickens are our speciality. I have been seven years now in this chicken-rearing district, and I am sure "Y. B. A. Z.'s" Brahmans would find more favour than the blue stockins.

I again repeat that the Brighton, Tunbridge Wells, and Maidstone Shows ought to give separate classes for White, Grey, and Coloured Dorkings, and if Cuckoo and Speckled could be added so much the better. I am sure the committees would, in a year or two, find it greatly to their interest.

I trust "WILTSHIRE RECTOR" does not think that I am blinded by fancy. I can assure him I am no fancier of either coloured Dorkings or Spanish, but Silver-pencilled are particular pets of mine; still I am not blinded to the fact that they are not the fowls for this district. As for eggs, we are not desirous to compete with the foreigner when we can do so much better with white-legged chickens. Let us, therefore, improve our local breeds.—B. P. BRENT.

POULTRY SHOWS IN THE SOUTH.

I AM obliged to "Y. B. A. Z." for his courteous response to my request for some suggestions on the subject of southern poultry shows.

Some points have, I think, been clearly established by the discussion of the question in your columns. First, we see that southern exhibitors are quite prepared to support both new and existing shows in the south, provided that the schedules are framed in a liberal spirit, and due notice is given of the time of meeting by advertisement. The neglect of either of these conditions is fatal to the success of a poultry show.

Some of our southern managers, however, have not yet learnt this lesson. Take the case of the Kent and Maidstone Show: having merely by the chance mention of this Exhibition become aware of its existence, I applied for, and received its schedule. I found that by Rule 5, all exhibitors were required to reside in or occupy land in Kent; that no person could send stock unless he had been three months a subscriber, and that all animals and poultry must have been in the possession of the exhibitor three months previous to the Show.

Take, again, the case of Dorking, where the Show is confined to Dorking fowls. Obviously in cases such as these, what southern exhibitors want is not found. The next point we owe to "Y. B. A. Z."—namely, the wisdom of attracting

visitors to the poultry show by annexing it to an agricultural exhibition, of which it is sure to become the most popular part.

Again: it seems clear that the feeling of exhibitors is in favour, not merely of reviving in the south some good poultry shows, to be combined, as in the very successful case of Basingstoke, with an agricultural exhibition; but, also, that there is a prevalent and just idea that London ought to give us, once or oftener in the year, a poultry show as good as Birmingham; and here let me say, though not a member of the Poultry Club, that in my humble judgment we owe them thanks for the late Islington Show, which, although in its infancy, is by no means a puny bantling, but a bouncing healthy child. If the Crystal Palace Show comes to life again, all the better for the south.

Lastly: As "Y. A. B. Z." points out, we all may do something for the revival of southern shows by personal effort in our own neighbourhood. With an instance of this I will conclude.

Having read in your columns some three weeks ago, the origin of Lord Tredegar's Show, I sent my gardener with half a dozen pens of fowls, some of which had won laurels elsewhere, to a neighbouring agricultural gathering, among the roots and implements of which no cock had ever crowded. The final result was, that a neighbour seeing the birds, caught some of his fowls and added them to the collection. The next result was, that the fowls attracted more attention than either roots or implements, and when I went in the afternoon I could scarcely reach my pets. The third result is, that some members of the Committee are actively organising a poultry department at their next annual show. So from little beginnings may arise —, but I will not trespass longer on your space. The snowball is started and will gather as it rolls.—BRAHMA POOTRA.

ARE HAMBURGH FOWLS PROFITABLE?

I AM not much addicted to public speaking or writing, and, therefore, not up to prefaces. Poultry is my hobby. I dearly love my poultry. I live in the centre of a good-sized town, but have a tolerably good run for my poultry; yet I have not been altogether satisfied with the fowls I have kept. At first I bred and reared a lot of splendid Buff Cochins. These, after laying a very few eggs—say, seven or eight, wanted to sit and proved a great nuisance, frequently three-parts of them were broody, and I had scarcely any eggs from a dozen large and well-kept Cochins. And don't they eat! The quantity of food consumed by them astonished many people. I soon grew tired of my Cochins. Next, I had some Dorkings. These are splendid fowls for a farmyard, the best for general usefulness, and most profitable for the farmer, but not suitable to me as a fancier. I tried Game, but the chickens from the eggs (stated to be from first-prize birds), which I purchased, did not come true to colour, and other points, so they were soon given up. I do not like Spanish. I admire Game very much, but I think that Hamburgs will satisfy me better than any other breed, and I much wish for your opinion, or that of "WILTSHIRE RECTOR." I am happy to say I am not "ossy," and he sympathises with me and my hobby. I wish he would give us more of his articles concerning poultry. I will now tell you what I wish for. I want a breed of poultry "as special pets and favourites, with a possible view to an occasional exhibition," good egg-producers, tolerably hardy, easily reared, and not large. If you or "WILTSHIRE RECTOR," think with me that Hamburgs would be best, please inform me which are considered the more handsome, the Gold-pencilled or the Gold-spangled, and which the more striking as regards the markings, &c. Silvers would never look so well on account of the smoke. I shall also be very glad if any one will inform me through your Journal, the best and cheapest way to procure really first-class birds to breed from, "with a possible view to an occasional exhibition."—PARTLET AND CHANTICLEER.

[It is a pleasure to me to give any information in my power. I would say to the writer of the above, "Try, try, try again." Success in poultry matters never waits upon any but the persevering. "A tolerably good run;" by this I imagine something better than a small yard, probably an

orchard as well. A clerical friend of mine has gone through a similar course of trials and disappointments, especially in regard to Cochins, and has now settled down with Golden-pencilled Hamburgs. After three years' experience of these birds, he told me not long since, that he never means to change. Their never being broody, the vast number of eggs, and the moderate quantity of food eaten have established them firmly in his favour. These, then, I would recommend, supposing the run be worthy of its name. If otherwise, why not try Spanish? they would soon become favourites. A Spanish hen is singularly beautiful, no breed has a finer expression of face.

As to procuring the birds. I frequently see advertisements in this Journal, of fowls of all breeds for sale at moderate prices; and I was looking the other day at some so bought that were very good, and which may produce better. The mistake is, to think you can get first-class birds at a small price. This can never be the case unless the advertiser is ignorant of the value of his birds. Mind and have your walk dry. I recently saw the best of fowls, but their walk was damp and shaded by high walls. If you have not gravel or a gravelly subsoil, put plenty of stone drains in your yard, they will cost but little. Damp cinder paths are apt to bring roup.—WILTSHIRE RECTOR.]

HAMBURGH FOWLS IN THE SOUTH OF ENGLAND.

I AM very glad to see the "WILTSHIRE RECTOR" advocating the introduction of Hamburgs in the south of England. I have always been a great admirer of this breed, and formerly kept Hamburgs, but on changing my residence, some time ago, was obliged to give them up, and substitute Cochins and Brahmans in their place. I am so far dissatisfied with the exchange, that I would gladly go back to my old favourites if I could induce them to respect my garden, and dread my gardener's indignation. I certainly do not find that superiority in Brahmans over Cochins which is claimed for them; they are undoubtedly more difficult to keep within bounds. I do not find them better egg producers; and though, in common with Cochins, they consume an immense quantity of food, they do not seem to make flesh any faster. If any of your readers can suggest to me a mode of keeping Hamburgs, consistently with due regard for my garden, I should certainly return to them, and would embrace Dorkings also, but for the same objection. My garden is not walled, and the fence of my yards is only 6 or 7 feet in height, easily surmounted by either Dorkings or Hamburgs. The yards open on to a meadow of rather more than an acre, affording a good run; but even my present birds when let out prefer to leave the field, and come and torment my gardener, making comfortable holes for dusting themselves under our very windows. By netting over my yards I might certainly keep my birds in, but I am afraid they would not fare very well under such conditions. I was led to adopt Cochins and Brahmans as the only breeds possible under these circumstances; but shall be very glad to find any method of altering my arrangements, and the "WILTSHIRE RECTOR'S." letter has induced me to reconsider the subject.—A SOUTH COUNTRYMAN.

WORKERS SHORT-LIVED.—The age to which worker bees may attain is not easily ascertained, and opinions differ widely respecting it. But since the introduction of the Italian bee, we may readily determine how old they usually get to be. If the native queen of a common stock be removed about the middle of May, and a fertile Italian queen substituted, we shall scarcely find one common worker among a thousand, on examining the colony about the first of August ensuing. If the substitution be made about the end of July, the proportion of common workers remaining at the end of October will be about one-fourth or one-fifth of the whole number. It is, hence, evident, that the duration of life in the workers is greatly dependant on the season. When forage abounds and bees are industriously gathering stores, their span of existence appears to be comparatively short; and we may estimate that during the height of the honey season they do not, on the average, live longer than

five or six weeks; though they perish more from accident and exhaustion than from actual old age.—(*California Farmer.*)

YOUNG BEES FOUND REVERSED IN THEIR CELLS.

I VENTURE to suggest that this rare occurrence may possibly be the result of a "mistake" made by the grubs themselves, instead of the mother bee. If the latter is really the culprit, I think there must be an abnormal arrangement of eggs in the ovaries; the manner of oviposition rendering it very unlikely that any power of misplacing exists in the performance of that function. On the other hand, it is at least curious, that numbers of contiguous larvae should, without some physical cause, display similar aberration of instinct. It will be remembered by observant apiarists, that the young grub for some days after it is hatched, lies in the form of an incomplete ring, or crescent, on the base of the cell, and only assumes the straight form after it is sealed over.—JOHN P. EDWARDS.

MY APIARY IN 1864.

At the close of last winter my apiary consisted of twenty hives, of which, in the summary I always draw up of the condition of every stock at the end of March, Nos. 1, 2, 4, and 11 were placed under the head of "weak in population;" Nos. 12, 13, 17, 19, and 23 as "moderately strong;" Nos. 3, 5, 6, 7, 8, 15, and 22 as "strong;" and Nos. 10, 14, 20, and 21 as "very strong." Every hive is at that time thoroughly inspected, so far as its capabilities to that purpose will allow; and I find this annual spring summary very useful, while it is highly interesting to compare the subsequent performances of each hive with its condition at that early period. I may have to refer to this subject farther on in this paper, when treating of the honey harvest.

One stock only had been lost during the winter, and that, a fine artificial hive of driven bees of the previous autumn, was suffered to die of starvation through culpable negligence on my part. This is, I believe, the only stock lost during the winter of three successive years, from an average of about twenty kept; and it might, by the timely administration of a few ounces of food, have been most easily saved. Being very populous, it is probable that my honey harvest would have been increased in a corresponding ratio.

Having a sufficient number of colonies, it was my object, from the very beginning of the season, to obtain honey, and not swarms; so that the majority were supered, and otherwise treated, to carry out that purpose. The theory of my practice formerly was to allow a certain proportion of the hives to swarm, so as to keep up a proper succession of young stocks; but now, since I have arrived at the adoption of the system of artificial swarming, to the almost entire exclusion of natural swarming, I find it easy to maintain the apiary in good working strength and condition, while devoting more of the hives to the purpose of honey-making. I consider myself a gainer in every way by following out this plan. The bee-keeper who works his apiary scientifically on the depriving system, will find it, as a rule, more to his advantage to purchase an occasional swarm or stock to supply any vacancies that may occur, or to renovate exhausted hives, than to devote any part of his own apiary to the purpose. For years my own apiaries have been managed on this plan, with a large share of success. Of course much more care and attention is necessary than by that of allowing hives to swarm and taking the chance of an odd super from any that does not swarm.

I will now give a short history of all my hives, including any swarms which may have been added to them during the summer.

No. 1.—From this stock every comb, save one, was removed for an artificial swarm. At the close of summer the box was filled with new combs, and well supplied with sealed honey. No honey fell to my share.

No. 2. A large octagon box.—Supered on May 9th with an octagon glass box, 7 inches in depth. On June 4th this was raised on a second octagon, of the same diameter, but

10 inches deep. These were both filled, the lower division containing a quantity of brood. Exclusive of this, 37 lbs. of nice honeycombs were taken.

No. 3. A ten-framed hive.—Queen from original Ligurian obtained from Mr. Woodbury. Supered on May 9th with large square glass box, 13 by 7 inches. Honeycomb, 36 lbs., of prime quality.

No. 4. Flat-topped straw hive.—A swarm of 1858, which has been a most prolific honey-giver. Raised May 14th on an octagon Stewarton-box, furnished with empty combs. When the queen had commenced laying eggs in the lower division the old straw hive was removed, the bees driven out, and transferred to the box. It now promises to make a nice hive. It is worthy of remark that, although eight years old, the combs in the straw hive appeared by no means worn out, and were, at the time of removal (July 11th), occupied by five times the quantity of brood and eggs that the lower and newer box of combs contained.

No. 5. An eight-frame box.—Supered early in May with an octagon Stewarton-hive, which was raised on a shallow eke on June 5th. From this, though not filled, 31 lbs. of excellent combs were obtained.

No. 6. A ten-frame box.—On May 9th a large but shallow nine-bar super was given. The bars fit the frames in the stock-hives. Honey taken, 30 lbs.

No. 7. Adjuster-hive.—Old combs in a very dirty state in the spring, and hive very light, but strong in bees. The adjuster super having been slipped down over the stock-box, communication was opened into a space of about 13½ inches, by 6 inches in depth. From time to time, according to the bees' progress in comb-building, the super was raised an inch or two, until a depth of 11 inches had been attained. This hive afforded me 37 lbs. of beautiful honey.

No. 8. A ten-frame box.—Supered early in May with a bar box similar to that of No. 6. After the bees had about two-thirds filled it with combs, a swarm was thrown off the last week in May, and a stop put for a time to any further progress. Eventually the hive regained its strength, and a fine box of honey was taken; nett weight, 27 lbs.

No. 9. A flat-topped straw hive.—Stocked with a purchased swarm on May 19th. No honey given by it.

No. 10. Ten-frame box.—My original Ligurian stock, having a young queen raised from the brood, after the untimely death of the old Ligurian queen, caused by her own subjects in the previous autumn. A shallow bar-box super was first put on; three others of similar size, but without top, bottom, or bars, were slipped in between the super and the stock until a box of 13½ inches square by 15 inches deep was filled by the bees. This contained an enormous weight, but unfortunately the queen bred in the lower part of it extensively. Having removed the supers, and forcibly excited the bees, all the comb which contained any brood, or showed signs of having been used for breeding, was mercilessly excised, and given to another stock for hatching out. One of the ekes was taken away, and the rest returned to the bees to make good any deficiency. Eventually 40 lbs. of prime and pure combs were taken as my share of the spoil.

No. 11. Large octagon-box.—The bees would not work in a super, nor did they appear to become very populous until rather late in the summer, when a swarm was thrown off, and, unfortunately, lost altogether. This swarm flew to a neighbour's house, and entered a small crack in the brick-work below a window-sill, taking up their quarters under the flooring of the bedroom. They were smoked out with a great deal of trouble, but not saved.

No. 12. A flat-topped straw hive.—A late swarm on the 11th of July, the previous summer. The honey-harvest was virtually over by the 18th of the same month, yet late as it was the bees filled the stock, and collected about 4 lbs. of honey in a super. The hive was in good condition early in the year, but whether owing to throwing off a swarm undiscovered, or from want of fecundity in the queen, I cannot say, but it did not answer the expectations formed of it. A nice bell-glass of 12 lbs. 8 ozs. was the total amount of the harvest afforded.

No. 13. A frame-hive.—Brood-combs at different times were removed for forming artificial swarms, and the majority of the bees taken at another for the same object. This hive, though subjected to such severe deprivation, has recovered its strength.

No. 14. Eight-frame box.—Hybridised Ligurian stock. A large octagon glass box put on May 1st. On the 18th a second box, without bars or top, was slipped between the stock and first super. These formed, unitedly, an octagon super 13 inches in diameter by 14½ inches deep, which was completely filled, and removed on the 16th of July, weighing 72 lbs. nett, of the finest and richest honeycomb I ever saw. A second super, partially worked, was then put on in its place, and the bees added 3½ lbs. to its contents. Total weight of honey obtained 75 lbs. 8 ozs. This hive is an artificial swarm of 1862, headed by a pure Ligurian queen, given to me by Mr. Woodbury, being fertilised by a black drone, her bees are, of course, hybrid, but do not seem to be any the worse as honey-storers on that account. This hive gave me 50 lbs. of honey in supers last year. The stock is very heavy and populous at the present time.

No. 15. A ten-frame box.—An artificial swarm formed by driven bees last autumn. Deprived of several brood and honeycombs this summer for strengthening artificial swarms, and 10 lbs. 8 ozs. of rich honeycomb removed in frames from the stock-box, empty frames being substituted, the deficiencies were quickly filled up.

No. 16. A fine swarm, purchased a week after being hived. In bringing it home by rail every comb fell. The bees were but little injured. On being liberated they went quietly to work, but a few hours afterwards suddenly poured out of the hive, and flew right off, without collecting together in the air, so that no one could distinguish in the least the direction they took. After a minute search and inquiry the swarm was given up as lost. About 7 o'clock in the evening a neighbour's gardener called to say that he had just discovered the swarm in a holly tree close to the ground, only about 50 yards from my garden. The bees had to mount over some very high trees and descend almost perpendicularly. Having hived and brought them home, I transferred them to a frame-box, first taking the precaution of putting in a frame of nice brood-comb, removed from a non-honey-collecting stock, thinking it possible that there might be no queen with the swarm: however, on inspection a day or two afterwards a fine queen was discovered. This being a common stock I killed all the drones, and in so doing let fall the comb on which I had just found the queen. The weather was very hot, and it was a complete smash. I collected the bees as well as I could, but saw nothing of the queen; but she afterwards proved to have been uninjured, and must have been taken up with the rest, as I found her on one of the frames before leaving. This hive was subjected to many drawbacks in the removal of combs and bees—nevertheless, it is now tolerably strong and well filled.

No. 17. A ten-framed box.—Supered with the rest—never worked very well; and I believe a swarm was thrown off and lost from it on a Sunday, when no one was near. A super of 15 lbs. 8 ozs. fell to my share.

No. 18. A ten-framed box.—An artificial swarm raised this summer. Mr. Woodbury kindly offered me a sealed royal cell from one of his best Ligurian stocks. I at once made a nucleus from No. 13 by removing a comb of well-advanced sealed brood, together with a sufficient number of bees, confined them within doors for a day, after which liberated the bees, and fixed the royal cell just cut out from its own hive in the brood-comb. A week afterwards a fine queen was at liberty, and the nucleus-box was removed to Mr. Woodbury's garden for the purpose of being near to his Ligurian drones. The plan seems to have proved successful. She is a beautiful queen, and her offspring are apparently pure. By their own exertions, and the great breeding powers of the queen, together with the assistance of a comb or two from other hives, this nucleus has been built up into a fine stock.

No. 19. An eight-frame box.—Afforded a nice super of 12 lbs. weight.

No. 20. A ten-frame box.—Supered early in May. This, one of my very best working hives, while filling a large super most rapidly, unfortunately threw off a swarm. Honey taken, 23 lbs.

No. 21. A ten-frame box.—A four-bar super, of the great depth of 15 inches, was filled by this time. Weight of honeycombs, 31 lbs.

No. 22. An octagon-box, which filled a super with 15½ lbs. of honey.

No. 23. A new adjuster-hive.—Some comb made, but no honey stored in the super.

No. 24. An artificial swarm raised this summer.—The bees destroyed the first of two young unimpregnated queens given to them, though every precaution was used.

Having given a short account of each hive and its doings, I will now add a table which will more plainly demonstrate the amount of my honey harvest for the year 1864.

Hives.	Weight. lb. oz.	Hives.	Weight. lb. oz.
No. 2	37 0	No. 14	75 8
3	36 0	15 artificial swarm taken	10 8
5	31 0	17 swarmed	15 8
6	30 0	19	12 0
7	37 0	20 swarmed	23 0
8 swarmed and gave ...	27 0	21	31 0
10	40 0	22	15 8
12	12 8	16 hives	440 0
13* artificial swarm taken	6 8		

The foregoing table shows an average produce of $27\frac{1}{2}$ lbs. from each of the sixteen hives (notwithstanding that several threw off swarms, or were deprived of artificial swarms), which is, I imagine, far above the usual average afforded by the majority of apiaries, consisting of more than six stocks, in any known season. By referring to the early part of this paper it will be seen that the four hives which, in spring, were weak, afforded an average supply of 9 lbs. 4 ozs.; the five that were only in a moderately populous condition, also an average of about 9 lbs. 4 ozs.; the seven set down under the head of strong show an average of 26 lbs. 10 ozs.; and the four named as very strong exhibit an average of 42 lbs. 6 ozs. Thus will be seen the importance of maintaining every hive in the highest possible condition as to population during the winter and spring. Had the summer turned out a less abundant honey season, many of the hives which came under the category of weak and middling would have done nothing at all. Therefore my advice is to let no weak hives be put up for the winter; and if any hive shows signs of weakness in early spring join it to another. My time was so very much occupied in the early part of this spring that it was quite out of my power to attend properly to carrying out this rule, or I have no doubt that a larger supply of honey would have been the result.—S. BEVAN FOX, Exeter.

TAKING HONEY FROM COMMON HIVES.

THERE are many individuals, and, perhaps, some amongst the readers of THE JOURNAL OF HORTICULTURE, whose circumstances do not permit them to make use of the new and improved hives, or the methods adopted by means of glasses and caps, whereby what is termed virgin honey is obtained.

For the benefit of those, therefore, who have only bell-shaped straw hives, I can recommend the following as a good method for obtaining honeycomb equal in beauty and purity to any I have ever seen produced in glasses. But I must premise that the person who would put it in practice, must first acquire the simple art of driving. Well, then, supposing a large swarm (either a top or two casts united) comes off at the commencement of good weather, and the season continues favourable, it will be found that at the end of four or five, or at most six weeks, the skep, if of moderate size, is quite filled with honey and brood. This can easily be ascertained by feeling its weight. If satisfied that it is so, remove the skep to a little distance, and drive out about half of the bees, with their queen, leaving the remainder to hatch out the brood, and carry on the labours of the hive. The expelled bees may occupy their former position. The skep from which they have been driven must be placed at some distance, not less than twenty or thirty yards.

Leave it thus three weeks longer and drive it again, and you will find that you have a skep well filled with beautiful honey, and with scarcely any young bees in the brood cells. Take two instances out of many.

1863.—Swarm lodged in a common straw hive July 9th; driven August 6th; driven finally August 20th; contained 36 lbs. of honeycomb equal to any wrought in glasses.

1864.—Swarm lodged in a common straw hive July 4th; driven August 3rd; driven finally August 22nd; and contained 30 lbs. of pure honeycomb equal to any wrought in glasses.

* Gave an artificial swarm and 6 lbs. 8 ozs.

Precautions. Drive on a damp or cloudy day, or in the forenoon or afternoon when the heat is moderate, and after driving the skep place the floor-board on the mouth, and invert it with the edges of the combs to the zenith.

There is little danger of expelling too many bees, the nurses adhere so tenaciously to the brood-combs.

In the case of doubled casts there will occasionally be no eggs laid by the young queen for five or six weeks. The driven bees may be profitably returned to the old stock, or sent to the heather, if the driving takes place at the end of July.—R. S.

A NEW BEE BOOK.

SEEING the request of your correspondents, "R. S." and a "CONSTANT READER," that a "Bee Book" might be written by Mr. Woodbury, I quite coincide with them, that it would be an inestimable favour to all apiarists, and I feel sure it will greatly assist beginners, by describing those recent discoveries in bee-keeping which Dr. Cumming states have not been made; but which I fear he has not seen, and, therefore, concludes no one else has. I send this in acknowledgement of the many inquiries I have made of Mr. Woodbury through your Journal, and his practical suggestions have answered my purpose in every respect.—T. S.

CAUTION IN OPERATING WITH BEES.

In operating upon bees at this season much caution seems to be necessary, and experience is almost the only guide to enable one to meet emergencies which may arise.

When examining a hive on the 24th of September I allowed it to remain on its own stand, and shifted each frame separately into another box a yard or two on one side of the stock under inspection. I soon observed that the bees which took wing, instead of returning to their own hive, were crowding into the unicomb-hive which stood close to it. I at once completely closed the entrance to prevent any farther ingress, and kept it closed until the operation was completed, and the dusk began to quiet the uproar occasioned in the apiary. On looking into the unicomb I saw that it had received a vast accession to its population, but no fighting had taken place; the bees were, however, in a state of great agitation, but on the following morning I found that the queen in the unicomb-hive was under arrest. I allowed the cluster to remain undisturbed, as I did not value the queen, until the evening, and then dispersed it with a few whiffs of tobacco smoke. The officers in charge soon began to give way, and a general cry of "sauve qui peut" seemed to be the order of the day, with a grand run upon the stores. The queen regained her liberty, and is now, I believe, all right, but I failed to discover her this morning. She is, however, so small, scarcely any larger than a worker, that it is sometimes difficult to single her out. Nearly all the bees which had betaken themselves to the unicomb returned to their own hive the next day.

The disturbance brought a vast number of robbers into the field, and a great many entered the hive and helped themselves to honey whilst my search for the queen was going on, and after all was finished the hive was almost in a state of siege. Two hives, I noticed, were particularly busy in sending out foragers, and the entrances of these, and also of the adjoining hives, were at once stopped to prevent fresh reinforcements from being sent to the invading army. The robbers, when loaded, returned home, and clustered outside their respective hives, and comparative tranquillity was soon restored in the besieged hive. When the robbers had all departed I closed its entrance with perforated zinc to prevent any further inroads being made before the bees had recovered their equanimity after the disturbance caused by the inspection. I afterwards contracted the entrance, so as to admit of only a single bee going in, and the inmates seem to have kept the burglars at bay, although many rascals were hovering about the hive all day.—J. E. B.

RULES FOR PURCHASING BEES.—Select two-year-old stocks of large size, that swarmed the previous year. It has been demonstrated that such stocks have young and vigorous

queens, and are generally well-conditioned, promising a healthy generation. A very old stock should be rejected, even if it swarmed the year before and contained a yearling queen, for the obvious reason that the bees, having been bred in the old contracted cells, will be found of small size and insignificant in numbers. If you take your hive away to get a swarm placed into it, always purchase the first or prime swarm, and see that it is given you. Do not be put off with a second or late swarm. Choose a stock to commence with as you would choose a wife—get the best you can find. If you obtain one in the old box-hive invert it, and secure the bees by a cloth tacked securely over the bottom. Take it home when the air is cool, attend to it regularly, obey the directions as given, and then congratulate yourself on having started right. In the purchase of bees there are many things it is well to observe. Remember if stock-hives are to be procured, ascertain the age of the queen. To select a young, healthful mother seems to be a forward step towards a vigorous progeny—(*Flanders' New Bee-book, American.*)

BEES NOT CARNIVOROUS!

So all the efforts of my inventive genius are vain! and all my bright visions of fame and profit at an end! Bees will not eat meat after all. I suppose that point is now settled, although when the subject was first broached, the diffident uncertainty of our great aparian oracle "A DEVONSHIRE BEE-KEEPER," obliged one to reconsider conclusions long foregone. That bee-covered "turkey drumstick" which "RUBY" describes, had certainly an awkward look about it. Its appearance indicated a decided gustative attraction for the occupants of the hive in which it was placed. "Seeing," they say, "is believing," and when "RUBY" was assured, and that by a lady, that bees for many generations (apian I mean), had been invigorated to bear up under the rigour of many long and dreary winters by the virtue of a morsel of meat, I do not quite see how he could be guilty of such ungallant incredulity, as to reject the testimony of his fair informant, corroborated, as it seemed, by the evidence of his own observation; and I think, further, that "RUBY" was quite right in publishing in your pages a fact which, if verified, would prove of the utmost value to your aparian readers. The experiment has now been repeated, and, as many of us expected, signally and universally failed. Had it been otherwise, what a "wonderful success" my "patent bee food" might have obtained! However, if I thus lose all hope of profit by invention, I shall relish my honey as heretofore, and not allow disgust to mingle with my amber sweet, by thinking of dead flesh whilst eating my bread and honey.

Alas! how many of our cherished ideas must be consigned to the "limbo" of crude notions! But never mind, we are still going on with our education, and if we mount up to real knowledge on the footsteps of our own proved ignorance, all the better for us. It will make us less confident, more diffident, and call forth our observing faculties, by the process of individual mental cross-examination. I do not know, after all, whether meat-feeding would be an improvement upon the usual methods—certainly not upon the Woodbury inverted bottle-feeder, for honey or syrup, which I consider by far the simplest and most efficient mode of supplying the wants of an impoverished hive yet invented. I thought certainly, had it not been for some of these celebrated modern notions, being recently exploded, of making some of my poorer hives participants of the approaching Christmas festivities, by inviting them to an early dinner (weather, of course, permitting), of roast turkey and a little Scotch ale, the latter "mulled" or plain as they might prefer, but I shall now leave them to their undisturbed hybernation amidst the more genial fare of their own selection, and indulge in the retrospective fancy of my projected Ruby-Cumminic apian feast.—RUBY BLUSH.

I STATE this as a fact. I have tried my bees with meat, and they will not eat it. One day I gave them a mutton chop a little warm, and watched them to see if that would entice them to eat it; but they only had a lick or two and then left it. I allowed it to remain all day and night, and then I took it away. I might as well have given them a

stone. Do you think "RUBY" was in love with the lady he speaks of? If so, she might have emptied the teapot under the hive, so that it was only a lot of tea leaves that he saw, and not bees. Ladies are sure to be up to some of their tricks if they have a not-required lover.—P. R. L.

FOOD OF BEES—STANDS FOR HIVES.

I PROMISED in my last letter to give the opinion of a friend, an old and successful bee-keeper, as to their carnivorous propensities. He says, decided bees will eat the flesh and even the bones of birds, chickens, &c., if they are driven to it by hunger, but that while they have anything else to eat, they will not touch flesh. If this be true, as seems likely, the evidence of "R. S." in this week's paper, would not decide the point. Is it not possible that bees, like men, may by long use become fond of food which was at first unnatural and distasteful?

Have any of your correspondents noticed the great partiality of bees for an early, and in my opinion, very charming spring annual, the *Limnanthes grandiflora*?

Now, that I think of it, I would mention another thing in this rambling letter. I often hear the question, What are the best stands for single hives? Taylor, I think, in his manual, mentions the danger of wooden posts decaying under ground. But I have never read or heard of the simple and ornamental plan I have for some years adopted for my few exposed hives, a Neighbour's cottage-hive among the number—viz., a common white drain-pipe, of either six or nine-inch diameter. They are about 4 feet long, and may be sunk in the ground to the required depth, without any danger of rotting or shaking. I nail pieces of wood at right angles on the bottom of the floor-board so as to fit well within the pipe, and this keeps all steady.—A. W. B.

[The employment of a drain-pipe for a hive-pedestal was first suggested by our esteemed correspondent "A RENFREWSHIRE BEE-KEEPER," in page 128 of the first volume of our New Series. There can be no doubt of its forming an excellent and enduring support either for hive-ranges or for single stocks.]

ADDENDA.

COOKS, COOKERY, AND WILTSHIRE BACON.

"Do you think you could prevail upon 'WILTSHIRE RECTOR' to give us a slight addendum to his recent excellent article on cooks, bacon, &c.? He says the grand secret for success in making bacon, is the letting off the brine; but he does not tell us the exact how and when, to do this. Then I want to know how he recommends its being cooked, for I can scarcely ever get it twice alike at different hands—sometimes quite flat and nearly raw, sometimes frizzled and curled into fantastic forms, and a mere shadow of its former self; in fact, all ways, but very rarely sent up in an enjoyable and wholesome manner. It is like boiling a potato, simple enough, and yet how few can do it! Can 'WILTSHIRE RECTOR' tell us a good way of smoking bacon to get it mild?"—W. H. B."

I most willingly comply with "W. H. B.'s" wishes, and will answer his questions to the best of my knowledge and ability. First. As to the letting off the brine. I manage it in this way. In one corner of the wooden tray before described, is a circular hole an inch in diameter. The tray is set upon blocks with a gentle slope towards the hole. A pan is put on the ground, and from first to last of the whole month of the curing every drop of brine runs off towards the hole, thence down into the pan. Secondly. As to the cooking. I have the slices cut very thin, as thin, indeed, as possible; they are just popped into a fryingpan, turned the moment the heat is seen to be through them, and then they remain on the other side a still shorter time. This is a nice operation, dependant for its success upon the cook's care and good judgment. Usually we suffer frightfully for a week at least, when we have a new cook, and even then periodically, when that functionary is careless or out of humour. The cooking of bacon is so nice an operation that it reminds me of an anecdote concerning a certain lover of pears, who was found with his watch in his hand, one eye upon it, and

the other upon a pear placed on the chimney-piece. "What can you be doing, doctor?" exclaimed the gentleman upon entering the room. "Hush, my dear friend," was the reply, "that pear will be ripe in just ten minutes, after that it will be spoilt." Turn the ten minutes into ten seconds, and the anecdote applies to the cooking of bacon.

As to "W. H. B.'s" last inquiry, I can say nothing, having had no experience of smoking. When the fitches are taken out of the tray, they are rubbed all over with bran, and then hung in the kitchen. Pieces are cut from them as wanted.

Another letter which has come into my hands runs as follows:—

"Dear Mr. Editor,—In a paper from a "WILTSHEIRE RECTOR," lately published in your admirable Journal, I find a curious proposition as to the advisability of transforming wives into cooks, or cooks into wives. May I be allowed to enter my solemn protest against the former idea? The latter is, of course, no business of mine, and it may be that cooks possess a cure for exigeant husbands as well as for bacon.

"Good cooks are, doubtless, excellent things, but I grieve to be obliged to own how much better are men than women cooks. I believe this is an acknowledged fact. Let me then base a proposition on the fact—let the husbands be the cooks; let men at Oxford take honours in devilled bones and réchauffées, and let hashes and friassées settle the wranglers at Cambridge.—AN OVERWORKED WIFE."

"AN OVERWORKED WIFE!" This title goes to my heart, there should never be even one overworked wife. Let me hope that it is an imaginary title; let me fancy that this overworked wife is no wife at all, but a maiden lady, who imagines wives are overworked. But yet, after all, I fear it is a true title, for she is so overworked as not to have read my paper carefully. If she turns to it some leisure minute—say after the bairns are in bed, the gudeman asleep in his chair, and the servants doing their duty, she will see that no "proposition is made as to the advisability of transforming wives into cooks, or cooks into wives." As to the latter, I merely quoted a true anecdote; as to the former, I simply stated that woman is the cook, that it is so. I said, "Among the countless thousands of benefits and comforts coming to us from woman's presence in the world, stands this—she cooks for us." And with few exceptions it is so, I imagine, throughout the world, or at any rate throughout our world—England. All I suggested was, that it would be well if ladies knew how to cook, giving as a reason, "that the best mistress is the one who knows how work is done", and jokingly looked to lady cooks as a resource in extremity. How many a woman by birth a lady, and now in the colonies, wishes she knew a little more of the useful!

By the way, I see another reason, conclusive to my mind, that "OVERWORKED WIFE" is a wife, inasmuch as she confesses, albeit she is grieved to do so, that men cook better than women. So she knows us, through one good specimen, her lord, and acknowledges us to be superiors even in cooking. But for my part may no morsel ever reach my mouth that was not cooked by woman's hands. Let the light fingers still mould my pastry, turn my pancakes, stir my preserves. Let no man cook for me. If he must do something of the kind, I would trust him to make my pickles, perchance they would be all the sourer. Even wranglers would make a sad hash of the hashes, I should not be surprised if they went into the ashes. Devoutly wishing that "OVERWORKED WIFE" may be so no longer, I will bid her good-bye, just quoting one line of Tennyson.

"Man for the field, and woman for the hearth."

Yes, even for the hot hearth.—WILTSHEIRE RECTOR.

REMOVING HONEY FROM HIVES.—Two years ago we tried the following experiment on a hive of bees, from which it was desired to take the honey:—Having bored a few holes near the top of the hive it was then inverted, and an empty box of the same size placed over it; both were then lifted into an empty tub, into which water was slowly poured, allowing time for the liquid to penetrate through the holes, but not too fast, in order to avoid drowning the bees. As the water rose among the combs, the bees found

their way into the empty box, which was then lifted off, and placed on the bee-stand. The box, full of water and combs, was then lifted gradually out of the tub, the water escaping by the holes through which it entered. The whole operation occupied but a few minutes, and scarcely any bees were lost. The short time necessary prevented the honey from becoming dissolved, and as the greater number of cells are sealed up, there is really little danger of such loss being sustained. After the water was drawn off it was found to be only slightly sweet, the combs soon became dry, and the honey was in no way injured.—(California Farmer.)

[We fancy very few British apiarists will be induced to try this mode of depriving bees, which seems indeed to savour not a little of the primitive method of washing gold as practised in California and other diggings.]

COWS MILKING THEMSELVES.—Simultaneously with your articles on this subject, I met the following notice in Mr. Baring-Gould's "Iceland," and copy it in vindication of the poor maligned hedgehog,

"I noticed a cow with a great hamper tied between her hind legs. This, said the farmer, is a cow which milks herself and when once they have taken a fancy to their own milk, a complete circulation is established and they give up eating."—A. Z.

OUR LETTER BOX.

SILVER-PENCILLED HAMBURGH COCK'S TAIL (R. W.).—Inadvertently the description we gave at page 384 is that of a Spangled Hamburg cock's tail. The Pencilled Hamburg cock's tail should be ample, full-feathered foundation, colour black, the sickle and principal feathers edged with silver. The black should predominate, except in the tail coverts, where the silvery may be increased.

GUINEA-FOWLS ROOSTING IN TREES (W.).—Very young Guinea-fowls are like young Pheasants, being susceptible of cold; but the same similarity exists when they are grown up, and they are then hardy enough to roost anywhere. A hard-plumaged bird with his head under his wing, and his body in the smallest compass, his legs gathered well under him and buried in the feathers, does not suffer much from cold or wet. Instance Pheasants in coverts.

YOUNG CHINESE GOOSE LAYING (H. A. F.).—It is not a very uncommon occurrence, and we have known the young reared when the ground has been often covered with snow.

POULTRY MAKING A RAID (R. L.).—Put wire-fencing 5 or 6 feet high. Paint it green and it will be hardly visible. It will keep out all fowls, but we will not answer for Turkeys or Guinea-fowls, especially the latter. They are the hyenas of domestic poultry.

COCHIN-CHINA FOWLS (F.).—We cannot recommend any dealer. It is entirely a matter of taste whether the White, Buff, or Partridge-feathered variety is selected. We prefer the Buff. When we require fowls of any breed we attend an exhibition, and buy pullets from one owner and the cock from another. Never breed from brother and sister birds.

DUCKLING GAME BANTAMS' LEGS AND WEIGHT (R. T. Bantam).—Game Bantams' legs may be of any colour, but they must match. The lacing of a Sebright should be moderate, neither heavy nor light, but if choice is necessary between extremes we should prefer the former. It must, however, be lacing, not blotchy, or in patches of any colour. There is no fixed weight. They cannot be too small, and formerly the cock was limited to 17 ozs.

COCKATOO EATING ITS FEATHERS (C.).—The cause of your Cockatoo biting off the tops of its feathers is an irritation of the skin, owing to its having had food of a greasy nature. Feed it on soaked or boiled Indian corn, scalded bread without milk, hemp and canary seed, and let it have a tepid bath occasionally on a warm day. If the bird will not bathe in a soup plate full of tepid water, pour the water over it through the fine rose of a watering-pot.

LICE ON A GOLDFINCH (G. R. B.).—Dust under the feathers, and especially under the wings, with flowers of sulphur. Wash the cage thoroughly, and fill the crevices of the floor with the sulphur.

WOODBURY FRAME-HIVES (William Carr).—It is perfectly certain that well-made frames, when properly filled with comb, will keep their perpendicular position without the aid either of propolis or bottom guides of any kind. Imaginary difficulties appear in this case to have led to fancied improvements, which, so far as we can perceive, have not even the merit of novelty to recommend them. The one you describe was tested and rejected by Mr. Woodbury many years ago.

NOTCHED BAES FOR FRAME-HIVES (A. W. B.).—We have no doubt that Messrs. Neighbour will, on application, readily supply the deficiency.

LIGURIAN QUEENS (J. M.).—The statement is untrue. Mr. Carr never possessed a Devonshire-bred bee.—A DEVONSHIRE BEE-KEEPER.

										58	340	

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 47.8°, and its night temperature 35.0°. The greatest heat was 62° on the 1st, 1837; and the lowest cold, 14°, on the 30th, 1856; and 5th, 1841. The greatest fall of rain was 0.56 inch.

THE DECAY OF THE ROYAL HORTICULTURAL SOCIETY.

ERO fiddled whilst Rome burned," and the mismanagers of the Royal Horticultural Society are fiddling whilst it is decaying. Were it not capable of noble results to a science so associated with home enjoyments and home decoration we might let them continue to fiddle; but they are,

by their erring judgment and misdirected trifling, ruining a Society capable of effecting too much substantial good for us not once more to record a warning, and to invite all who think as we do—that the Society is worth preserving—to rescue it from the peddling hands and Tartuffe heads that are now trifling whilst hastening its descent.

We have before us the regulations for 1865, and no more palpable evidence of fiddling incompetency was ever sent forth. Some glaring mistakes which characterised the proceedings of the current year have been avoided, and some small good alterations have been resolved upon. But there are quite as many small and great errors proposed to be committed. Let us note upon some of them in the order in which they occur.

What can justify the expense of a *déjeuner* to the Fellows, whilst the Society is so deeply in debt?

Why are so many bands of music to be engaged? One on each occasion is quite sufficient.

Why are there to be fortnightly meetings and weekly shows? Why not have them fortnightly, and simultaneously? The supply of plants and the attendance of competent judges of fruits and flowers would then be quite sufficiently taxed.

What is the gain to either the Royal Horticultural Society or to country Societies by these being allowed to enter into union? Will the funds of either be strengthened by the combination?

Why are the spring meetings fixed to be on the same days as those of the Royal Botanic Society? Will this increase the number of visitors?

Why is the one Great Show to be held on a Saturday? It is a day which was formerly chosen by the Royal Botanic Society, and which they found so inconvenient that they changed their great show days to Wednesday. If it did not answer the purpose of the Royal Botanic to hold their Shows on Saturday, we fail to see how it can be advantageous to the Royal Horticultural Society to do so. We believe Saturday to be an objectionable day on two grounds. First, because, since the extension of the railway system, and the facilities the various companies afford for people to pass from Saturday to Monday in the country, many take advantage of that privi-

lege, and it is not one of the frequent flower shows that will induce them to remain in town. And, secondly, it is objectionable because it deprives the exhibitors and their assistants of the rest and quiet of the following day. It is late on Saturday night before they can repack their plants and leave the place of exhibition. Many of them are travelling all night, and do not get home till Sunday morning, and then they have to proceed to unpack and replace their collections. Or, those who object to travel all night and to unload their plants on Sunday morning, are compelled to remain in London at great expense and much inconvenience till the following Monday.

We observe that the Pelargonium Show (including Scarlet and Variegated varieties, which are not in bloom till July), is to take place on the 3rd of June, when it is not possible to exhibit the Scarlet and Variegated varieties, and for which no provision is made at any subsequent Shows in July when they are in their best condition. Considering the fine effect produced by these at the Exhibitions last year, and the great interest they created, we regret that some provision is not made by which the public may see these attractive flowers in their greatest perfection.

How is it there are no Roses in pots included in any of the spring Shows? Last year the Azalea and Rose Show was the most attractive of all the spring Exhibitions, and in the programme for this year there are no Roses mentioned, except at the Great Show on the 1st of July.

Such are only a few of the fiddling changes and grave mistakes to be perpetrated in 1865; but where is there a single powerful effort apparent that might stay the Society's decay?

That the Society is decaying needs no other proof than that exhibitors will not contribute to its shows; that the public refrain from attending them; that all speak of the Society with contempt; and that its Fellows next February, if the account is made up correctly, will be found largely diminished. We say this because we know, if the management is not changed, many very influential Fellows who will either diminish their subscriptions or cease subscribing entirely.

Now why is this?

The displeasure caused by the undignified, because illegal, retention of office by those members of the Council who were irregularly elected, has spread wider and sunk deeper than those gentlemen seem to appreciate.

The neglect of the Chiswick Garden, unsurpassed though it is by any ground near London in picturesque beauty, and having no rival anywhere to its collection of hardy fruit trees, and the degradation of such a garden to be a mere nursery for plants to feed the South Kensington anomaly, is a source of indignation and regret to all who love gardening, and who hold the opinion, ignored by the Managers, that a horticultural society should promote horticulture rather than pantomimes. Selling Grapes from the splendid vineyard to the Fellows might be justified; but to sell them to any customer at the wholesale market price, and to retail punnets of Straw-

berries at a profit, bought wholesale from Covent Garden fruiterers, is far below the dignity and is totally beside the objects of a national Horticultural Society. What would be said of the Linnaean Society if it bought beetles at sixpence, and had a stall in its rooms for retailing them at a shilling?

When Fellows turn to the Society's Exhibitions they cease to wonder that there are no exhibitors, for they find that the prizes are to be dependant in amount upon the money taken at the doors. We have heard of strolling players dividing the entrance money among themselves; but we never heard before of a national Society expecting valuable productions to be conveyed to their exhibitions at a large certain expense and risk, and that the exhibitors, like the players, after certain deductions, were to divide among themselves the shillings taken at the entrances! That this is not a mode of remuneration befitting the Society needs no argument, and that it is not satisfactory to exhibitors is demonstrated by their absence. There were two at the last Chrysanthemum show!

Such a deficiency in the attractions is soon appreciated by the public; and when to this is added the entire absence of judgment in fixing the exhibition days, we hear it observed too often, "We cannot go to-day, nor would it be worth the time and trouble if we could."

The able lecturers who, gratuitously and at no small expense of time, have responded to the Society's request to deliver lectures in the room at South Kensington, have ample reason for complaint. No man likes to have an apparent proof before him, afforded by empty seats, that either he or his subject is not highly esteemed. Yet every lecturer must have been thus benumbed, though the conclusion he drew was not a fair conclusion; for the real causes of such scanty audiences have been the absence of public announcements, and ill-judged selection of times and hours.

The members of various Committees have ample cause for complaint. The Show Committee's circular asking for a reply to be sent by the 15th of October, was not sent at all to many of the Fellows, and to others not until after the first week in November. In another Committee on a subject of taste, meetings were summoned without any hour being named, and reports made without some of the ladies being summoned to the meeting at all. But these are not the worst features in connection with the Society's Committees; for we know of the names of influential members being published as belonging to those Committees though they were never asked to belong to them, and were never summoned to the meetings. Now, no excuse can palliate this. It was a liberty which should be taken with no member of a society; and—whether intentionally or unintentionally matters nothing—it was inducing the public to confide in the Committee having the aid of those distinguished members, though the Committee neither had, nor sought to have, their counsel and assistance.

With these facts patent, will any one wonder that the Society is rapidly decaying? Will any one dare to pen a sentence in defence of such mismanagement? Will the Council not look around and see if there is not some one who, instead of being their pilot and aid, is their misleader and encumberer? Will they still permit the blundering, neglect of details, and inattention to routine, which has so characterised and so offended in the official conduct? Will they, in despite of demonstrations of the Society's decline, still cling to expensive musical contests and such irrelevant extravagances, instead of the promotion of the objects of the Society and the benefit of its Fellows?

If they do so permit, and do so persist, then the decline of the Society will soon ripen to its fall; and it will be ever a subject of sorrow, but of no surprise, to know that vast donations and a noble income have been lost to horticulture, and will leave one more example that wealth only ministers to profusion, and power only gives opportunity for increased folly, when intrusted to the presumptuous incompetent.

TRENTHAM BLACK AND CHASSELAS VIBERT GRAPES.

In reference to a notice of these two Grapes in your Number of the 22nd inst., I beg to say that I have them both in a cold viney.

The Trentham Black is a very strong-growing Vine, and retains its foliage in a green state longer than the Black Hamburgh. With me it has set its fruit much better the second year of training than it did in the first. It does not require much thinning, and is, I should think, a very good trusser. I do not think the flavour so rich as that of the Black Hamburgh; but, then, the Grapes that I have of the latter variety are first-rate. It is, however, exceedingly sweet and good.

The Chasselas Vibert grows weakly, and has taken three years to reach the top of the house. It is, however, a good bearer, and ripens its fruit very early. Its flavour is excellent, and it is a pretty good trusser. The bunches are not large.—M. A., Oxon.

THE NEW ROSES.

I now resume to, I hope, conclude my anatomy of the lists of new Roses, about which I feel more nervous than ever, as I am continually receiving letters from those who say they have trusted to my recommendations for this year's orders, and I should be very sorry to be a blind leader.

PERNET.

53. *Madame Fresnay*.—Very vigorous. Flowers large, well-formed; beautiful lively rose.

54. *Mesdames Sœurs Chevalliers*.—Very vigorous. Flowers large, full; colour of wine lees with a slaty tinge.

55. *Triomphe des Français*.—Very vigorous. Flowers large, nearly full, blooming in clusters. Lively crimson red.

M. Pernet does not seem over-sanguine as to the first of these, only placing it at 15 francs. The second is hardly a colour for English tastes; and the third being nearly full will, I fear, put it in the background.

GUINOSSEAU.

56. *Heliogabale*.—Flowers vigorous, large, blooming in clusters, brilliant velvety red. Very free-flowering.

A. L. BAUMANN.

57. *Madame James Gros*.—Very vigorous. Flowers large, well made, clear crimson, lightly bordered with rosy white.

DEFAUN.

58. *Maréchal Bazaine*.—Flowers medium, cup-shaped, well formed; shaded rose in the inside, carmine outside of petals. Flowering freely in autumn.

H. JAMAIN.

59. *Marguerite de St. Arnaud*.—Very vigorous. Flowers large, well-formed; white, with a blush tinge, passing to pure white.

LIAAUD.

60. *Monsieur Boncenne*.—Very vigorous. Flowers large, cup-shaped, blackish velvety purple.

These five raisers are modest; like single-speech Hamilton, they only give us one production; and I should hope that Jamain, the raiser of Maréchal Vaillant, will give us something worth growing again.

Besides the above, M. Eugène Verdier announces the following, of whose parentage nothing is said; and the only information is that he has a part of the stock. I hardly think that one would be justified in looking for much from them. These are—

61. *Ardoise du Châlet*.—Slaty purple shaded with carmine.

62. *Charlotte Corday*.—Purplish red; reverse of petals lighter.

63. *Dunois*.—Carmine red shaded with violet. Somewhat like Vicomte Vigier.

64. *Forster*.—Imbricated; fine deep red shaded with violet.

65. *John Keynes*.—Scarlet red, shaded with maroon.

66. *L'Abondant*.—Very free-flowering. Fine lively red, with very marked light border.

67. *La Coquette*.—Lively shaded red, violet tinge; three or four rows of outside petals fiery red.

68. *Léonie*.—Currant red; reverse of petals lilac.

69. *William Bull*.—Flowers full, globular; lively cherry red. Superb.

M. Lacharme announces two white Roses which he rightly designates as hybrids of Bourbons and Noisettes, I think

coming from him, that they may be improvements on the white Roses we possess. They are—

70. Baronne de Meynard.—Flowers medium, well formed, very fine; pure white.

71. Madame Gustave Bonnet.—Flowers medium; form of Centifolia Rose; virgin white, shaded rose and carmine.

TEA ROSES.

72. Madame Charles (Damazin).—Very free flowering; flowers very large, full; sulphur yellow, salmon centre.

Marechal Niel.—Very vigorous; flowers large, globular; deep shaded yellow. Very fragrant.

This last Rose I had the pleasure of seeing at Paris, and I am quite persuaded if it opens as well with us as it does in France that it will be a decided acquisition. It is of the same class of flower as Cloth of Gold, Isabella Gray, &c., having more analogy with the Noisette than the Teas. The colour is very fine, and the shape good.

BOURBON.

74. Adrienne de Cardoville (Guillot, père).—Flowers medium, very full, open well; tender rose colour.

75. Madame Collet (Liabaud).—Dwarf flowers, medium size; pale blush; free flowering. Good border Rose.

76. Madame Vachez.—Imbricated, small flowers; blush rose, passing to pure white.

77. Marguerite Bonnet (Liabaud).—Flowers large, imbricated; flesh white.

78. Miachael Bonnet (Guillot, père).—Flowers medium; very full; beautiful lively rose.

79. Prince Napoleon (Pernet).—Flowers very large, nearly full; fine lively rose.

80. Souvenir de Louis Gaudin (Trouillard).—Flowers medium, full, well formed; fine purplish rose, shaded with blush.

Finis! and an end there must be to such wholesale importations, for assuredly this French invasion is becoming alarming; and now where is the selection? I should say Hybrid Perpetuals Rushton Radclyffe, Souvenir de William Wood, Charles Margottin, Duc de Wellington, Duchesse de Medina Coeli, Duchesse de Caylus, Madame Charles Verdier, Marguerite de St. Arnaud, Jean Rosencrantz, Triomphe de la Terre des Roses, Xavier Olibo, Monsieur Moreau, Charles Wood, and Souvenir de Bernardin de St. Pierre. In Teas, Marechal Niel, Bourbon, Adrienne de Cardoville, Miachael Bonnet; and Hybrid Noisette Baronne de Meynard; and I may add a fine crimson Rose of English origin, KING'S ACRE, raised by Mr. Cranston. Whether one is right in these conjectures time alone can tell.—D., Deal.

TIME FOR VINE-PLANTING—MANURING PEACH TREES.

I HAVE recently purchased a few Vines, and been recommended not to plant them in the border until March. I shall feel obliged if you will kindly inform me whether a little quicklime mixed and stirred well in the border to kill the worms, &c., would be beneficial or otherwise to the Vines when planted. The lime is, I should observe, what has been used in gas-making.

I have also purchased a few Peach trees to grow in the same house as the Vines, and being a novice in these matters, should be glad to know if water or liquid manure is to be given during the winter months, and in what quantities?—CESTRIA.

[It matters but little at what time you plant the Vines. If the ground is in good order, you might plant them now, breaking the balls gently so as to disentangle the roots. If not used to it, the best way for you to do this will be to take the ball of earth and roots out of the pots, and then place the ball in a tub of water heated to 60° or so, and then with your fingers wash away all the earth. This will enable you easier and better to disentangle the roots and to spread them out to their full length, and pack them nicely in light sandy soil, from 9 to 12 inches below the surface. When thus nicely spread out and covered with 2 inches of soil, give water at about 80°, then fill up with soil and cover over the ground with about 15 inches of warm litter, and thatch or put on tarpauling to keep out extra wet. So

treated the roots will begin to move during the winter, and be in a good state for meeting the expanding and lengthening buds, and so treated we think the sooner the Vines are planted the better it will be for them. If you cannot give this coaxing to the roots conveniently, we would advise you to take the foreman's advice and keep the Vines in their pots in a protected place until March, and then plant as advised above by spreading out the roots. In this latter case, the cooler the top of the Vine is kept the better, allowing the buds to break naturally. There is a third method which, as you have the house, you might adopt, but for your lack of experience, and by it your Vines would do the very best the first season. Get some crates or shallow baskets of rough woven material—say 3 feet long, 2 feet wide, and 4 inches deep. Place some rough pieces of turf and leaf mould on the bottom, and a sprinkling of light sandy soil, and on these, after pruning the Vines, spread out the roots and cover with rough loam and leaf mould. Set the baskets on the floor of the house, water as needed, and about the end of May plant the baskets at once at the suitable depth in the border, taking care not to injure the tops. You will gain a month's growth by this extra care, and no check need be given. The simplest plan would be to plant any time before spring, and keep the roots comfortable by protection.

The best time to apply quicklime for killing worms in the border will be a week or two before planting, and then the alkali will be gone before the roots come into contact with it. We here allude to common lime or quicklime, such as is used fresh for making mortar. That is a very different thing from lime that has been used in gas-making. Of that we should not think of using any in a Vine-border, as when employed at all it should be by a practical man who knows something of its strength, and its power to kill all vegetation when given in large doses.

As to your Peach trees to be grown in the same house, you do not say whether they are in pots or planted out; but in either case they will need little water during the winter, and that little may either be clear or weak manure water until the buds begin to swell. Then the soil should be moistened, or there is a danger that the buds will drop. In fact, during the winter the soil should never be dust dry, or the same thing will be apt to occur; but when the trees are at rest the soil should be dryish rather than very wet. As soon as the trees push well manure water may also be given freely as they need it. It should, however, be weak and clear, and also varied. Thus a peck of soot and a pound of lime would do for forty gallons, and two pecks of horse-cow, or sheep droppings would do for an equal quantity, but it should stand a fortnight first; and then for the next brewing in either case half the quantity would do. Two ounces of superphosphate, and one ounce of good guano would do for three gallons. A good plan is to use the manure as a top-dressing and pour the water over it, removing the manure and adding fresh as the first becomes exhausted.]

GROWING MANGOLD WURTZEL AND SWEDES ALTERNATELY.

I HAVE in hand about six acres of arable land, and a much larger quantity of grazing land. On the six acres I am anxious, if possible, to grow Mangold Wurtzel and Swede Turnips, year by year, for my sheep, and fattening bullocks. Can this be done without injury to the land by judicious and sufficient manuring? If so, in what shape would you advise me to return to the land, when I manure it, that which I remove from it in my crop? The roots I should propose feeding off the land.

I have not sufficient arable land for a proper rotation of crops, and I am unwilling to disturb any of my tenants. Garden ground produces the same crops year after year without perceptible injury, and I am disposed to think that the same may be done elsewhere, if the right manures, and a sufficiency of them are returned to the soil. I make plenty of farmyard manure.—POSSUM.

[We do not anticipate that you will have any difficulty in carrying out your wish. The market gardeners about Romford, and elsewhere grow Potatoes and Cabbages alternately, always have heavy crops, and use no other manure than that

which they obtain from their own stables, and from the London yards. At Lois Weedon Wheat is grown every year on the same plot. We should advise you to trench the ground, bringing the lower spit to the surface annually. Your farmyard manure will be the only fertiliser you need.]

CHRYSANTHEMUMS.

MR. SALTER'S, VERSAILLES NURSERY, HAMMERSMITH.

The winter garden here is just now a beautiful sight, the Chrysanthemums, numbering about 1800, being at present in full perfection, and the whole are arranged with exquisite taste, the brightness of the colours, which would otherwise fatigue the eye, being skilfully toned down, so as to produce a brilliant, but not dazzling effect. With this object Oranges, Araucarias, various Ferns, and some other plants are introduced in groups here and there, especially near the entrance; baskets of Woodwardia radicans, and other Ferns are suspended from the roof; tall Scarlet Geraniums are trained on the back wall above the Chrysanthemums; and in front of the Geraniums are ranged fruiting Orange trees in pots. The small oval beds in the centre walk where the banks of flowers recede are chiefly centered with tall plants of *Centaurea candidissima* surrounded by charming little Pompons, studded with innumerable blooms. Fine as Mr. Salter's annual show has been for several years, that of the present season far surpasses them, and whoever has not seen it can form but a faint conception of its beauty.

Mr. Salter is so well known as the raiser and introducer of beautiful novelties, as to render comment on that head unnecessary, for not a year passes in which he does not acquire some striking novelty out of the thousands of seedlings which he himself raises, independent of the many other sources which his extensive connection enables him to draw from. Of the new varieties of 1864, we noticed last autumn several which were of high merit, and especially Princess of Wales, which appears to be destined long to rank as one of the most beautiful in cultivation. Its colour, a pearly white tinged more or less with rose lilac, according to its age and other circumstances, is most beautiful. Prince Alfred is another noble flower, very large and full, with broad, finely incurved petals of a rosy purple; also General Bainbridge, orange amber, and which is already deservedly a great favourite for exhibition. Lord Clyde, glowing crimson, is of a splendid colour, and Robert James, a fine bright cinnamon and orange. Rev. Joshua Dix is another fine show flower, the colour orange red, and the same may be said of Sir Stafford Carey, dark chestnut, with golden points. Besides these we noticed Mrs. Haliburton, a very double sulphur white; Grange Lodge Rival, orange salmon; Lallch Rookh, dark ruby rose; Mrs. E. Miles, bright yellow, a good exhibition flower; Donald Beaton, St. Margaret, Bella Donna, Florence Nightingale, Sam Slick, Pelagia, St. Patrick, and some others.

Still more interesting were the seedlings for 1865, though all of these had not been named, nor would this be done till more had been seen of their character; for Mr. Salter is very careful not to send out inferior varieties, and for one seedling that he retains he often destroys hundreds. Virgin Queen is a large, fine, close flower, pure white; Ranunculus has a very broad petal, crimson, lighter at the back; King of Denmark is a large dark lilac, with silvery back, and is of fine form; and Mr. Wynness, a dark crimson approaching to mulberry, is one of the richest colours we have seen in the Chrysanthemum. Venus, delicate lilac, finely incurved, was to have been sent out last year, but sufficient stock had not been propagated, and it is, therefore, numbered with the new varieties. Mrs. Brunlees, cinnamon, with orange points, is very attractive in colour; and Golden Ball is remarkably high, forming a fine golden orange ball. Two fine rose lilacs exist in Albert Helyer, and Lady Carey, both of which are very large and beautifully incurved, and Pink Pearl, another of the same colour, but shading off to white, promises to be equally fine as a show flower and pot plant. Prince of Wales, mulberry, with a lighter centre, has the petals, or, more properly, florets broad, even, and beautifully incurved. Sam Weller, finely incurved, reddish cinnamon; Hercules, dark, very large and fine for conservatory decoration; Othello, a fine dark mulberry; Margaret Vatcher, bright

rose with a lighter centre; Golden Dr. Brock, a finely-formed amber sport of Dr. Brock; Imogène, lilac shaded blush, a fine conservatory plant; and Princess Margaret, a very pretty silvery rose anemone, are the principal of the other new sorts for 1865. We must not, however, omit mention of John Salter, which Mr. Salter considers will prove the finest flower he ever raised; as seen by us the colour was a reddish amber changing to amber at the centre, the petals remarkably broad and smooth.

Among Pompons were Lizzie Holmes, a very free and double canary yellow; Lady Dorothy Nevill, bright yellow; Miss Nightingale, a blush anemone, with a white centre, all of them varieties of 1864, and of older kinds, Capella, dark reddish chestnut, with an orange centre; Fairest of the Fair, a very attractive free-flowering lilac blush; Madame E. Domage, beautiful pure white; Salamon; Rose Trevenna; Mrs. Dix, blush bordered with rose, very fine; Madame Fould, cream; Danæ, golden yellow, and many others.

Many beautiful flowers of less recent large varieties offered themselves to the view at every turning, but being now pretty extensively known, it would be of little advantage to enumerate their names, a few however may be mentioned as useful for particular purposes. Thus—Abbé Passaglia, White Christine, and Her Majesty, make fine conservatory plants, and Cloth of Gold, though ragged, is excellent for the same purpose; Progne, is the only one having the same brilliant crimson carmine colour, whilst White Queen of England, a sport from the blush kind, is splendid for cut blooms. Beverley, another white, is fine for the same purpose, also as a pot plant, and Lord Ranelagh, Lord Palmerston, Lady Hardinge, Cleopatra, Sparkler, General Slade, Talbot, and Duchess of Buckingham, are adapted for both purposes. The old Quilled White is another kind, which, though not a florist's flower, is late and excellent for forcing and bouquets.

There were besides several of the Japanese Chrysanthemums, brought home by Mr. Fortune and others, such as Laciniatum, fringed white like a Dianthus, and pretty for bouquets; Late Yellow Dragon, a large, coarse-looking yellow; and Grandiflorum and Red Dragon, which were better than the others, and might be useful for conservatory decoration. As many persons are desirous of knowing what kinds are the most suitable for this purpose, we give beneath selections of twenty large-flowering Chrysanthemums, and the same number of Pompons, affording a diversity of colour, and suitable for conservatory decoration.

Large-flowering.—Beverley, White Queen of England, Mrs. Haliburton, Her Majesty, Lady Hardinge, Princess of Wales, Bella Donna, Marshal Duroc, Lord Palmerston, Lord Clyde, Frogne, Prince Albert, Sparkler, General Slade, Antonelli, Little Harry, Sir S. Carey, Jardin des Plantes, Yellow Hermine, and Golden Formosum.

Pompons.—Madame E. Domage, Mlle. Mart, Cedo Nulli, Madame Fould, Fairest of the Fair, Lilac Cedo Nulli, Rose Trevenna, Trophée, Adonis, Salamon, Jane Amelia, Requiqui, Aurore Boréale, Danæ, Mr. Astie, Général Canrobert, Canary Bird, Capella, Miss Julia, and La Rousse.

In the span-roof house adjoining the winter garden were several specimen plants in fine bloom, particularly Jardin des Plantes, and some seedlings, and in the lean-to against Mr. Salter's residence seedling Geraniums, obtained between a Nosegay and a scarlet kind, and which partook a good deal in the character of those raised by Mr. Beaton; also several Centaureas. One of these was the true ragusina, for which candidissima is very generally sold, and gymnocarpa, another, is very useful for winter. We also noticed a variety of Cineraria maritima called compacta, which has the merit of being of dwarf, compact habit, and two pretty Geraniums, one belonging to the Zonale section, with a well-marked horseshoe, and a white flower with a deep rose centre, and another named Madame Barre, of a very deep rose, deeper than Helen Lindsay, and of dwarf habit. A pretty hardy Sedum, provisionally named glaucum from its colour, used in the winter garden and out of doors, forms a pretty and very close carpet, and is well suited for edging beds and covering banks of earth.

Out of doors the borders were gay with Chrysanthemums in great numbers and variety, and though some of them had been exposed to 11° of frost (thermometer 21°), their general appearance was good. It was interesting to notice

that whilst some kinds, as Lord Palmerston and Alma, were scarcely affected, others close to them were much injured.

MR. FORSYTH'S, STOKE NEWINGTON ROAD.

THE high position which Mr. Forsyth has taken in the last two or three years, gives this nursery a claim to more than a passing notice, though it is neither so extensive nor so well known as many others. It is, however, well worthy a visit at this season, when the show-house is filled with large and handsome specimen plants of the best varieties, both large-flowering and Pompons, and, though none too early, when we visited his establishment the other day, we were much gratified with what we saw. The centre of the show-house was occupied by a fine bank of plants, comprising a great variety of colours, and the shelves at the sides were filled with bushy plants, such as he is in the habit of exhibiting. Among these were Duchess of Buckingham, a fine white variety of the current year; a handsome specimen of Golden Christine, but which Mr. Forsyth considered the worst of those he had grown this year; Annie Salter, one of the best and most useful of the show kinds; Alma, 4 feet 3 inches across, and in splendid bloom; Arigena, amaranth, another fine show flower; Rifleman, and of Pompons there were excellent specimen plants of Cedo Nulli, Sainte Thaïs, and Général Canrobert.

Besides these, in the centre and other parts of the house were Beverley, now nearly over; Plutus, an excellent late-blooming yellow; Forsyth's Golden Trilby, a golden sport of Trilby; Jardin des Plantes, fine; Abbé Passaglia, Antonelli, General Slade, Indian red tipped with orange; General Harding, another fine sort of the same colour, with a golden shade, and which is very popular, both for cut blooms, and specimens; Raymond, Cherub, golden amber, with a rosy tinge, a fine late variety; Prince Alfred, and Princess of Wales, which have been everywhere so much admired; Nil Desperandum, Queen of England, and many other well-known varieties.

Of new kinds of 1864, we noticed Bella Donna, Donald Beaton, Empress, Pelagia, Prometheus, very large red; Mrs. Pethers, a rose lilac anemone; Lady Slade, a beautiful lilac pink; General Bainbridge, a general favourite; Sam Slick, Rev. J. Dix, a fine show flower; Robert James, another very fine flower, with broad petals, beautifully incurved; St. Patrick, Lallah Rookh, Mrs. Mills, and others on which we have already remarked. Among Pompons were Lizzie Holmes, Miss Nightingale, &c.

Besides the show-house two other houses were likewise filled with Chrysanthemums of various kinds.

At the Shacklewell Nursery, where Mr. Forsyth grows his bedding plants, of which he annually disposes of considerable quantities, a low span-roof house 70 feet long was filled with a healthy stock of Tom Thumb, Attraction, and other Geraniums. Joining this is a propagating-house filled with Pelargoniums, and bedding stuff. A galvanised iron tank for bottom heat had just been put in, zinc, which was formerly employed having been worn out in a single year. A span-roofed structure was filled with Geraniums, and several thousands of seedling Lobelia speciosa, the seed of which Mr. Forsyth is very careful in saving true. Another house contained a nice lot of Alma. Flower of the Day, and Madame Vaucher Geraniums, Azaleas, and some Camellias, and several ranges of pits were filled with a healthy stock of Cinerarias, Calceolarias, pricked out in the cold about a month ago, and just rooted, Mignonette for flowering at Christmas, Cytisus, Stocks, &c.

Great credit is due to Mr. Forsyth for the energy and perseverance with which he has worked himself up to his present position, for he owes it entirely to his own exertions, and with such qualities we look forward to his obtaining still greater success in the future.

NORTH AND EAST YORKSHIRE POMOLOGICAL SOCIETY.

I ENCLOSE you a report of a Fruit Committee which was held on the 3rd of November, at Thirsk. I am anxious to call your attention to it, as I think the same sort of society might be established with advantage in other parts of the country, in connection with the Royal Horticultural Society.

On comparing the different varieties of fruit together, the following sorts of Pears and Apples seem to be the most useful for general purposes, to be grown as dwarf standards or espaliers in Yorkshire. Of course there are many others which will do on a wall, but which are uncertain on standards.

DESSERT PEARS.—Louise Bonne of Jersey, Marie Louise, Seckle, Swan's Egg, Aston Town, Comte de Lamy, Gratioli, Easter Beurré, Winter Nelis, Beurré Diel, Knight's Monarch, and Roi de Wurtemburg.

STEWING PEARS.—Catillac, and Uvedale's St. Germain. To the foregoing may be added for some seasons, but as rather uncertain, Beurré de Rance, Gansel's Bergamot, Glou Morceau, Van Mons Léon le Clerc, Beurré Clairgeau, Althorp Crasanne, Beurré Bosc, Autumn Bergamot, and Dunmore.

DESSEET APPLES.—Court of Wick, Court-Pendu-Plat, Ribston Pippin, Pike's Pearmain (early), Golden Pippin, Golden Russet, Alfriston, Claygate Pearmain, King of the Pippins, Margil, Cox's Orange Pippin, and Scarlet Nonpareil.

BAKING APPLES.—Lord Suffield, Dumelow's Seedling, Alexander, Mère de Menage, Large Hunthouse, Large Cockpit, Blenheim Orange, Norfolk Beaufin, Yorkshire Greening, and Kentish Fillbasket.—C. P. CLEAVER, Appleton-le-Street, Malton.

[We quite agree with our correspondent in thinking that local pomological societies would be productive of great benefit. They might report annually which varieties of fruit had succeeded best, and give details of the soils and situations in which each variety attained the greatest excellence in the county. This would be exceedingly useful as a guide to all residents in the locality.—Eds.]

THE NEW AMERICAN PEACHES AT ANGERS.

Nearly, if not all the above are clingstones, vigorous from the graft, and free growers, now four years planted, and first fruited, 1864.

20 Exquisite Not fruited 1864.

21 Golden Purple "

22 Canary "

23 Honey..... Small, only one fruit, 1864.

24 Stump the World..... Described as medium size.

Denning and Benade condemned. Honey, Early Tillotson, Colombia, Ascolea, Bordeaux, Bagby's Late, Pine Apple, Henriette, &c., not fruited yet.

Of the last five, Exquisite is described at page 152.

Golden Purple is above the middle size; suture well defined; rich lake colour on sunny side; freestone, melting,

juicy, with a rose-water flavour, red near the stone. Ripe in my orchard-house on the 20th of July.

Canary, ripe July 11th; above the middle size, with a distinct nipple, freestone, flesh yellow, melting, aromatic. Quite a usual southern Peach.

Honey, middle sized, freestone, very pointed, like an almond, pale red on the sunny side, peculiar tropical flavour. Ripe July 21st.

Stump the World, very large, blunt nipple, distinct suture, striped with red on the sunny side, pale red at the stone which parts freely, juicy, delicious flavour. A first-rate Peach; ripe on the 15th of August, very prolific, and deserving cultivation. It makes much wood and might succeed on a warm wall.—T. C. BRÉHAUT, Richmond House, Guernsey.

ORCHIDS IN FLOWER IN NOVEMBER.

BARKERIA Skinneri; Calanthe vestita nivalis, C. vestita flava oculata, C. vestita rubro-oculata; Cattleya bicolor (three varieties), C. labiata (seven varieties); Coelogyne agenaria, C. speciosa; Cypripedium barbatum, C. insignis, C. Fairrieanum, C. venustum; Dendrobium formosum giganteum; Epidendrum vitellinum major; Ionopsis paniculata major; Lælia anceps, L. anceps (variety), L. Perrini, L. Perrini grandiflora, L. prestans (many varieties); Lycaete Skinneri (many varieties); Miltonia candida, M. Morelliana; Odontoglossum grande; Oncidium barbatum, O. excavatum, O. ornithorhynchum, O. papilio majus; Phalaenopsis amabilis, P. grandiflora, P. rosea; Saccoclabium violaceum; Sophronitis grandiflora, S. cernua; Trichopilia tortilis; Vanda insignis, V. tricolor; Zygopetalum erinitum cœruleum.

The above Epidendrum vitellinum major has been in flower for the last seven months. Lælia anceps variety is very fine, one spike measures 4 feet 6 inches in length, with five flowers on it, each flower measuring 5½ inches across; one of the Lælia prestans is also very fine, with seven spikes on it, some bearing two flowers on one spike. Mr. Robert Warner, of Broomfield, informs me that it is a very unusual thing to see L. prestans with two flowers on one spike in this country.—CHARLES KEMMERY, Gardener to Thos. Jones, Esq., Ellerslie Villa, Whalley Range, Manchester.

IMPROVING OLD VINES.

SOME, perhaps, like myself with only one house for Vines, may be benefited by my experience.

The house here is a very old one, with two Vines, a Black Hamburg, and Black Prince, having stems as thick as a man's arm. Eight years ago they bore bunches so small that it made one quite miserable to see them, and my employer said I might try to improve them.

Being close to the house, and planted in a 12-feet gravel walk, where a border could not be made, I had to remove the gravel and earth to the depth of 15 inches or more without finding a root. Below that the roots were plentiful. I then broke the old earth up with a fork as carefully as possible, to avoid injuring the roots, and had ready a mixture of loam, a little well-rotted dung, and a few bushels of inch bones. Turfy loam from Epping Forest was the kind used. Reading about the same time in your valuable Journal, that some person grew Celery very fine by laying earthenware-pipes under the roots, I thought that was a hint for watering my Vines, so I laid rows of pipes amongst the loam with elbow joints close to the wall, put brickbats around each joint that the water might run out freely, and a lid to the top of each pipe, on which lid we can stand a plant to make all look tidy. I can pour about eighty gallons of weak liquid manure down, put the lid on, and all looks clean.

After filling the walk with the loam, &c., a little above the level to allow for settling, I put the clean gravel on just sufficient to make all neat. Rolling over that part for two or three years afterwards was like rolling over elastic.

The Vines did much better in the following season, and every year since then the wood has strengthened, and the bunches and berries increased in size. I have some bunches hanging now more than a foot long well shouldered, and coloured.

The expense was very little, and quite repaid itself in

the second season. I tried the walk this summer, and found it quite full of roots; but with the pipes I can give them all they want without again disturbing the walk.

Three years ago a friend removed with his master to a new place, where there was a viney in a very bad state, the bunches few, small, and shrank very badly, the Vines had not been planted more than eight or ten years. He asked my advice, and I told him to carefully take them up and renew the drainage and border in September. He hesitated. I told him it was so stated over and over again in THE JOURNAL OF HORTICULTURE.

He had the same loam, bones, &c., all ready as before stated, took the Vines entirely up, covering the roots with damp moss and matting, renewed the drainage and border, carefully planting the Vines, watering the roots, and gently syringing the leaves morning and evening, and made a little fire. One Vine only drooped, and that a Muscat.

In the following season the wood was short-jointed and promising, but there was not much fruit, but that we could not expect. In the last two years the crops have been very good, both in bunch and berry. He is greatly pleased, and his master well satisfied, so accept the best thanks of myself and friend for the benefit we have obtained from your valuable Journal, and often when I read I thank you and all your correspondents for the pleasure and profit I receive.—W. C.

MESSRS. FRANCIS & ARTHUR DICKSON AND SON'S NURSERIES, CHESTER.

WHEN I gave a notice of these nurseries some time since, I stated that I had been unable to go over the forest and fruit tree grounds. A friend has, however, supplied the deficiency, and the following brief account will perhaps be interesting to those of your readers who care for such things, for these grounds form one of the most extensive depôts for forest stuff, as it is generally termed, in the kingdom.

“Some eighty to ninety acres of ground are devoted to the cultivation of forest trees alone. In addition to the twelve millions of seedling Larch (not Laurels, as by an error of the press it was made to read), alluded to in THE JOURNAL OF HORTICULTURE of October 11th, there are also to be seen from five to six millions of transplanted Larch, varying in height from 18 inches to 4 feet, healthy, vigorous, and clean-grown stuff. Thorns or Quick are grown to an equally large extent, the stock being of very fine quality; and the same may be said of large quarters of Scotch Fir, Spruce, Spanish Chestnut, the Austrian Pine, also Pinus laricio, both of these last-named trees being very much used in the formation of plantations. They are both very valuable quick-growing Pines, admirably adapted for exposed situations. Then there are almost endless quarters of Hazel, Black Thorn, Ash, Beech, Birch, Horse Chestnut, Elm, Silver Fir, Hornbeam, Poplars, Sycamore, Willows, &c., offering to planters an extensive range for the selection of their materials that only great establishments like the Upton Nurseries can offer.

“It would seem that one other especial feature of the out-door nursery work is the production of plants suitable for game coverts, underwood, &c. For these purposes there is annually raised a very large quantity of Berberis aquifolium, which is much sought after for the formation of coverts, the berries being excellent food for pheasants, while the rabbits will not bark the plants. For the same purpose the Canadian Gooseberry—the stock of which, judging from the catalogues periodically issued by the large nursery firms, seems to be almost exclusively in the hands of the proprietors of the Upton Nurseries—is also extensively grown for coverts; the fruit, which abounds on the plants, is readily devoured by game, while the plant grows very vigorously, and spreads with amazing rapidity. It only requires to be more generally known to be extensively employed for this purpose. For the same end are also grown Black Thorn, Hazel, Hollies, Laurels both Portugal and common, in large quantities, and of all sizes and stages of growth; Rhododendrons, Snowberry, Sweet Briar, Privet, all of a superior character to what are generally seen. Pinus pumilio is also an excellent plant for covers, as it grows very densely, and game are fond of seeking it for shelter.

“The culture of fruit trees is another especial feature of

the Upton Nurseries. They are grown to a large extent, the variety of the sorts being in keeping with the area of their cultivation. Of standard-trained trees there are strong and handsome specimens of Apples, Pears, Cherries, Peaches, Nectarines, and Apricots. Of dwarf trained trees the quantity is very considerable, including Peaches, Apricots, Nectarines, Plums, Cherries, and Pears. The Peaches and Nectarines are as fine and handsome specimens as could be wished for. The growing taste in favour of fruit trees in the pyramidal form is apparent here by the extent to which they are cultivated. They are more ornamental than standard trees for kitchen gardens. The fruit is screened to a great extent from the force of the wind, and the trees occupy less room in the garden. There were here capital specimen trees of this shape of the best varieties of Apples, Pears, Plums, and Cherries. The fruit tree department also comprises Gooseberries, including all the best Lancashire show varieties, as well as sorts for kitchen purposes and preserving; Currants in extensive variety, Strawberries in all the leading kinds, Raspberries, &c."

Such are my informant's words; and I am sure, if this department equals in completeness the ornamental portion which I visited, it must be exceedingly well worth a visit.—D., Deal.

LILIUM LANCIFOLIUM CULTURE.

In your Journal of November 15th, in an article on the cultivation of the Japan Lily, *Lilium lancifolium*. Mr. Earley recommends January and February as the best times for potting it for successional flowering; but I think either of the above months much too late, as the roots are always active, consequently these should be potted as soon as the foliage is ripe.

I potted half a dozen large pots the first week in October, and I hope by the time at which Mr. Earley recommends potting, to have the pots full of roots, and very strong stems coming through the soil.

By this treatment I frequently have twelve or fifteen flowers on a stem, and should I want the plants in bloom by the first week in July, I can easily do so by placing them in a cool, airy place in the conservatory all the summer, whereas if I want them in August or September I have only to place them in a sheltered spot out of doors as soon as the weather will permit—say early in June.

They will require shading or to be placed under the shade of trees for a few days which amounts to the same thing. I mention my differing from Mr. Earley, because I do so from long experience in the cultivation of the above beautiful flower, and I am thoroughly convinced that half the miserable specimens often met with, are the results of late potting, and neglecting to soil up the roots thrown off the stems in the early stages of their growth.

I have this season ripened a quantity of seed of a fine variety of *Lilium lancifolium rubrum*, impregnated with the pollen of *punctatum*, and should be obliged by a few hints on the management of seedlings from any of your correspondents. I thought of sowing the seeds in a frame on a south border, in some well prepared ground. If I do so, with liberal treatment how long will it take me to flower them? —W. BROWN, *The Gardens, Elmdon Hall, near Birmingham.*

I HAVE read with pleasure the letter from your correspondent, Mr. W. Earley, on the cultivation of that most interesting bulb, *Lilium lancifolium*; and although I may agree with him, so far as concerns the production of specimen pots full of bulbs and their management, I totally disagree with him if he means to convey, that by his mode of treatment the plant and flower can be developed so as to show their beauties to advantage. To do this every bulb must be planted in a separate pot and flowered singly, carefully avoiding that most objectionable practice of staking, which I consider quite unnecessary. To my fancy it quite destroys the natural appearance of a stem, which has a most imposing effect when grown straight and free from support. I will now state the results of some years' experience which may be read with pleasure by some of your correspondents.

I have grown small *Lilium* bulbs to the weight of 1 lb. each, and which in three years produced flower-stems

5½ feet high, perfectly straight without the assistance of a single stake or support, and each bearing sixteen or eighteen blooms of such size that each petal measured in many cases 1½ inch across.

I have never tried to keep up a succession of flowers, but, as in any large collection some will flower earlier than others, I was quite satisfied to plant all my bulbs at the same time, and take the chance of their lasting quite long enough, at least until such time as the room in my small greenhouse was required for some other favourite. I commenced to plant at Christmas after having carefully examined the roots which I had always shaken out of their pots a month before. I removed all decayed roots and scales, of which latter very few ought to appear if the bulbs are healthy.

The soil which I have found most suitable for my purpose is an equal portion of fibrous peat, leaf mould, and maiden loam or well-decayed turf, with a good admixture of silver sand. Each bulb, according to its size, is planted in a pot 5 or 6 inches in diameter, well drained with some broken flower-pots, over which I place a layer of moss. I plant, not as Mr. Earley recommends, with the top of the bulb over the top of the soil, but well below the surface, bedding the bulb and covering it with silver sand, as a fancier would a valuable Tulip or Gladiolus. I give them, when planted, a good soaking of water, and then allow them to remain almost without any on the floor of the greenhouse until they fairly start into growth—say about 2 or 3 inches. The very fact that the natural habit of the bulb is to throw out a regular wig of roots at the point from which the stem starts, ought to be sufficient to illustrate the necessity of keeping it well under the surface, for I believe it is not from the roots of the under portion of the bulb that the flowers are nourished, but from those over the bulb at the base of the flower-stem.

When they reach this second stage, I shift each bulb into a nine-inch pot drained as before, taking care to plunge the plant still deeper; but being sure to leave at least 2 inches at the top of the pot for top-dressing in June. This top-dressing consists of good fresh soil mixed with well-decayed cow manure. These Lilies will bear good rich top-dressing. Manure mixed with the soil will do more or less injury to the bulb, and every particle of what is used until June should be as fresh and free from any decomposed matter (except the leaf mould), as possible.

After the final potting I place the pots on a sheltered gravel-walk in a southern aspect, guarding as far as possible against worms and slugs getting under the pots. I syringe every morning and evening, and never let the soil become quite dry. By turning the pots carefully towards the light when the plants show any inclination not to grow quite upright, I have never had occasion to stake them. By this treatment they will grow with beautifully polished leaves down to the edge of the pot, and will repay the trouble they may occasion up to the time of placing them in the greenhouse for flowering. This time I estimate by the size and condition of the buds, which ought to be well and fully formed before housing.—JOHN COTTER BEALE, Cork.

BACK WALL v. RAFTERS OF AN ORCHARD HOUSE FOR VINES.

WILL a Black Hamburg Vine do equally well, bear as large Grapes, and come as early to perfection planted against the back wall of an orchard-house, which wall is slated, as under the rafters of the same house, the Vine being planted in this case in the front border? The first plan I prefer, as the Vines under the rafters shade the fruit trees so much. If planted against the wall, I suppose there is no better plan than to let them grow perpendicularly, and train the laterals at right angles.—A. B.

If the trees in the front part of the orchard-house do not keep the light of the sun from the back wall, the Vine will not only do as well against that wall as if trained up the rafters, and but for the slate-facing of the wall the Vine ought to ripen its wood and its fruit earlier. If there is any risk of the wall becoming too hot, you could keep the stem half an inch or an inch from it. The bunches will be shaded sufficiently from the foliage. You might cover the whole of

the wall with Vines, and have low fruiting plants of other kinds in your front border.

Your White Grape is the Chasselas Musqué. To prevent cracking the soil should be kept rather dry as the Grapes approach to ripeness.]

MANAGEMENT OF BEDDING PLANTS.

NOTWITHSTANDING the very dry weather we have had this last summer, my flower garden has been one of the gayest in the neighbourhood; so much so, that it was the constant remark of my friends, "How gay your garden is! I have not seen any plants look better than yours this summer."

Now, how did I gain for my garden this celebrity?

First, I took great pains to get my plants into a healthy state before they were bedded out, neither overluxuriant nor stunted by hardening off, as one so often sees bedding stock at the beginning of May.

Secondly, After the first three weeks I gave no water at all. Thus am I more strongly than ever confirmed in the opinion that, in order to make bedding stuff do well and have a gay appearance to the garden throughout the summer, you should be particularly careful to have it in a good, healthy, stocky-growing state before planting out, and after it has taken good hold of the ground to withhold watering.

In dry weather watering plants in the ground, unless it is done in the most copious and thorough manner, does more harm than good, as it only draws the roots to the surface.—G. M.

PLANTS ON TRELLISES IN STOVES.

THERE are few persons able to afford a stove, or as some would term it, a tropical greenhouse, who would not like to have some creepers or twining plants in it, these being either trained around pillars, or upon trellises. Without mentioning the more rare and expensive kinds which are only sought after by the few, I wish to make some remarks on the more common and useful. Of this class some grow plants that do not flower freely, or which if they bloom do not afford a decided contrast between their foliage and their flowers. Some of the Tacsonias grow very freely, and when allowed to run will flower pretty well; but most of them are not all that is desirable in the colour of the flower, a circumstance which is much against them; but diversity so far from being an objection, should be sought for where there is room.

Another point worthy of consideration in connection with such plants, is that they should not be overcrowded. We all feel a certain degree of reluctance to cut away in the early part of the season whatever might add materially to the adornment of our houses. Sometimes this feeling is indulged in too far, and where the space is limited many of these strong-growing plants will exceed their proper limits if not attended to in time, and judiciously managed.

At whatever season this class of plants flower, I have found it a good practice when the flowering is nearly over for a time, to give them a good pruning-in, always being careful to remove as much of the old wood as possible, as it offers facilities for the lodgment of insects and their eggs in the fissures of the bark. On such occasions examine the plants well wherever they touch the pillar or trellis, for enemies are often found lurking in such places. When giving the plants their yearly cutting-in, and cleaning, I have found it a good plan to paint the pillars or trellises against which they are trained. When this is done yearly one coating of paint will be quite sufficient at a time. This always gives the house a healthy, orderly, and clean appearance. I often wonder that these little details are not more regularly attended to in places which are otherwise highly kept, and I venture to affirm that such details are far more carefully attended to in commercial establishments, where we may suppose that everything is done with a view to the greatest economy, and to secure the largest returns.

Having made these general observations, I may remark that there are two plants in a stove here which have this season been splendid for months. The house is span-roofed, about 24 feet long and 14 feet wide; at one end is planted in a prepared bed under the flooring, *Passiflora racemosa*

coccinea, and at the other end is a *Bignonia*, which has run over the whole of the roof. It is tied to wires about 1 foot under the glass, and from its appearance it is well named *incarnata*. The flowers are produced in good-sized clusters, and the plant has been already two months in flower, and is still very full of bloom.—G. DAWSON.

LECTURE ON "AILANTHI CULTURE."

THIS was delivered by Dr. Wallace, on the 10th ult., at the Literary Institution, Colchester. The interest which the subject possesses, and the probability that at no distant day Ailanthi culture may become one of the staple trades of the country, justify us in giving a more extended report of the lecture.

The Lecturer commenced his remarks by congratulating himself, that in the subject which he had selected for his lecture he had the peculiar privilege of unfolding a new page of natural history, and of introducing to their notice a tree both beautiful and valuable, and an insect recently acclimatised in Europe, elegant, graceful, and larger than any of our English species, easily reared and domesticated, the instrument of a pleasant pastime to the youth of both sexes, yet capable of contributing to our industry and wealth by a system of cultivation, to which was given the name of Ailanthi culture. This system, as yet in its infancy in Europe (the so-called centre of civilisation and commerce), had been practised for many years in China, Japan, and the Eastern Archipelago; and as the subject of Ailanthi culture, or the production of silk from the cocoons spun by caterpillars feeding on the leaves of the *Ailanthus glandulosa*, had up to this time attracted no marked attention in England, and as he had for many years devoted his spare time to the study of insects, and more particularly of butterflies and moths, he determined when he settled in Colchester, to embrace the first opportunity of investigating this new industry, and great was his astonishment when the opportunity he had so long coveted lay at his feet, for in his own garden he found a fine and beautiful tree, some 50 feet high, as well as a number of others in the town and neighbourhood. Dr. Wallace then went on to describe the tree, which was first introduced into England in 1751 (the seeds of it being sent to the Royal Society of London, by a missionary in China), but although its cultivation extended very rapidly, it was only used for ornamental purposes. The tree, he said, was of a remarkably hardy nature, quick of growth (as he showed by some beautiful specimens of this year's shoots), thrived admirably upon almost any soil and in any atmosphere, produced a remarkable foliage both for its size and the peculiarity of the odour which it sent forth, and was more easily propagated than any other plant. If no further use could be assigned to the tree, its culture was well worthy attention for ornamentations, and purposes such as that to which other wood was applied, but it was an especial object of interest as possessing another property of untold value—viz., the juices of the tree were converted by the natural chemistry of a caterpillar which fed upon the leaves into a silken or gummy thread, which, unravelled from the cocoon, and twisted, spun, and woven by the hand of man, became a fabric capable of clothing the human race. Having briefly noticed the history of the *Bombyx mori*, or the Mulberry silkworm, and especially demonstrated its unsuitability to the climate of England, he proceeded to lay before his audience the claims of the *Bombyx cynthia*, or the Ailanthus silkworm, a few living cocoons of which were sent to Turin by the Abbé Fantoni, a Piedmontese missionary in the north of China, and from thence found their way to Paris, where in June, 1857, the first living specimen of the butterfly saw its light in Europe. Since that time, it having been discovered that the leaves of the *Ailanthus* tree were its natural food, the *Bombyx cynthia* had spread over Europe and its colonies, and made its first appearance alive in England in 1861 or 1862. Dr. Wallace, aided by specimens which he had at hand, then gave an interesting description of this wonderful insect, commencing with it in its first stage, the egg, and tracing it through its several changes till it spun its cocoon, and finally emerged a beautiful insect, some extraordinary specimens of which he exhibited. Several interesting peculiarities of the insect were related, and par-

ticularly the extraordinary means which the caterpillar used to prevent the accident of the leaf upon which was the cocoon being blown off the tree; and the lecturer devoted some time to a consideration of the best mode of raising the insects. Upon the commercial aspect of Ailanthi culture he declined to give a decided opinion whether or not it would "pay," for the time since it had been tried was too brief to have established the value of the silk in the market, or, indeed, to introduce it in any bulk into commerce; but this he could say, that as regarded the tree in 1861 in France more than a million trees were planted and more than a hundred millions of seed sown (sufficient to plant fifty thousand acres), and that the demand for eggs of the insects exceeded the supply. The value of the Ailantise silk as sent from Japan and China was well known to consist in its extreme durability, but it could not vie with the Mulberry silk in lustre and gloss. It was not desired, he said, to set forward Ailanthi culture, as likely to supplant agriculture or even sericulture as regarded the Mulberry tree, but rather to supplement both, for Ailanthi culture if successful, would only be applied to those lands which from poverty of soil or other causes could not be otherwise cultivated,—viz., all sandy or sterile soils, railway banks, moors, mosses, bogs, rocky and stony ground, such as under cliffs, mountainous regions, sandy marshes and along the coast. It would not either displace Mulberry silk, for having a different texture, appearance, and inferior gloss it would be used for purposes quite distinct from those to which that silk was applied. Upon the question of cost he quoted statistics of the culture of the tree and the rearing of the worms in France, and showed that there a profit had been derived of £21 per acre upon ground otherwise valueless.

Dr. Wallace then concluded as follows:—I have now very feebly and inadequately (and omitting, for want of time, many points of great interest) laid before you, as it were, a leaflet from the great book of Nature, as yet undeciphered in England. Numerous as are the benefits we reap from her, there yet remain, even at our feet, many of her secrets uninvestigated many undiscovered sources of health and industry. Pisciculture as applied to our British sea fisheries, to the salmon, and to the oyster—sericulture on an extended basis, not confined to a single species as heretofore—the return of sewage to the land—the introduction of new species of living creatures from distant parts, suitable to our requirements, and susceptible of acclimatisation—these and other problems are presented to us for solution in the decade 1860-70. It is the duty of man, by patient investigation, to arrive at a correct interpretation of Nature's laws, and apply them successfully to his own benefit. The process is a slow one, and many mistakes must be made before the truth is elicited, but success in the end is sure. And with reference to this novel industry to English and European Ailanthi culture, it is worth while to note the remarkable events which have heralded its dawn. One hundred and ten years ago the tree was acclimatised in Europe, but not for sericulture. Had the silkworms then come over with the tree, they could not have been reared for many years to come for lack of foliage; but sufficient time was required for the tree first to become indigenous in Europe, Canada, Australia, and to manifest its reproductive and hardy nature. Then came a severe epidemic in Europe among the varieties of the Mulberry silkworm, inducing the proprietors to send out into the original silk-growing districts, India, Japan, China, for new and healthy kinds. This alone was possible by the aid of missionary enterprise: without the help of those pioneers of religion and civilization the Ailanthus silkworm would never have reached Europe. Various coincident movements in China and Japan threw open these countries to European research; the Ailanthus silkworm was discovered and sent to Europe, and the Ailanthus tree is at this time acclimatised, and abundant food therefore was now ready for the silkworm on its arrival. Then came a crisis in the cotton trade; the American war put a stop to our supply of cotton; substitutes were sought in every direction, and Ailanthi culture assumed at once a more important appearance; and not merely Ailanthi culture began to be investigated, but other species of cocoon-forming insects producing silk of hardy habits, and susceptible of acclimatisation in Europe were sought after. Thus the dream of the 14th century, which James I. vainly strove to

realize, is on the point of completion. Fortune will it be for England, fortunate indeed for Ireland, if land, hitherto valueless, can be so tended as to furnish, with easy care and slight cost, a tissue warm and durable, and fit even for the poor man to wear—fortunate will the women and children be if another healthy industry be open for their nimble and yet tender fingers. I cannot but be struck with the remarkable chain of events which has heralded these new projects, and I feel confident that at no very distant period European sericulture will rank high amongst industrial products. (Applause.)—(Essex Gazette.)

MINLEY MANOR.

THE SEAT OF RAIKES CURRIE, ESQ.

AMONG the many country residences which have sprung up of late years and become interesting in a gardening point of view, this must take a high rank, particularly when we consider that whenever the fruit from this garden has been shown at our great metropolitan exhibitions during the last three seasons, it has invariably either taken prizes or been adjudged equal to that from other first-class gardens.

After a long drive on a glorious September day, a friend or two and myself entered by one of the new lodges. The drive from this is wild in the extreme, the whole country as far as the eye can reach is hill and dale, covered with Heath and here and there a few patches of Firs bending before the wind. Along the sides of this new drive were fresh-planted Rhododendrons and American plants, generally with a backing of Larch, Spruce, &c., for shelter, which must be very necessary, for it is scarcely possible to find a more exposed situation so far south. At one of the turnings of the drive we came in full view of the château, as, I suppose, I must call it from its architecture being the pure old French. If the colour had been grey instead of red, it would have been easy to have imagined oneself wandering among the hills of Normandy. Its campanile with long steep slated top, the high almost perpendicular roof, and hanging bartizan, have an un-English look; and the barren situation would have made many pause before they chose such a site for a mansion.

Having found Mr. Meads, the gardener, he conducted us first to the range of houses, which consisted of seven divisions, all of the common lean-to form. Entering from the east end the first division we came to was a late Peach-house with a good sprinkling of fine fruit still upon the trees. Then followed the early division from which the fruit had been gathered in June, and the trees were covered with green healthy leaves, both front and back. Next to this was the early viney, in which were cut the Black Prince bunches that tried the veteran Grape-grower, Mr. Hill, at the Regent's Park June Show, Mr. Meads' bunches being heavier by 2 ozs., the three bunches weighing 8 lbs. 10 ozs., and Mr. Hill's 8 lbs. 8 ozs.

Next to this is a Muscat-house, and such Muscats! I am certain that it would have been possible to have picked out twelve bunches without finding their equal in any one house. Some of them must have been 6 lbs. in weight, and judging from the weight of some that had been cut, few of the twelve were under 5 lbs. The house is 17 feet long by 15 feet wide, and there is a Vine to each rafter, carrying eight bunches. The Vines were planted four years ago last June, and thirteen months after planting the Grapes from this house gained the third prize at Kensington. The berries of these bunches were large and plump, and of a clear rich amber colour. Joining this is the central-house, which is used as a greenhouse, and in which there is a Vine carrying thirteen bunches to each rafter. Two of the bunches taken as an average of the rest were found to weigh, one 4 lbs. 3 ozs., the other 4 lbs. 5 ozs., the whole being beautifully coloured. This house is 30 feet long and 17 feet wide. Next to it is a viney 35 feet long and 15 feet wide, wholly planted with Black Grapes. The average crop was ten bunches on each Vine. Some bunches of Muscat Hamburg here were very fine specimens of this precious variety. Some of them must have been of a good weight. (See account of the October Exhibition at South Kensington, at page 328.) It must be remembered that the Vines were upon their own roots, and that the Grapes then shown were

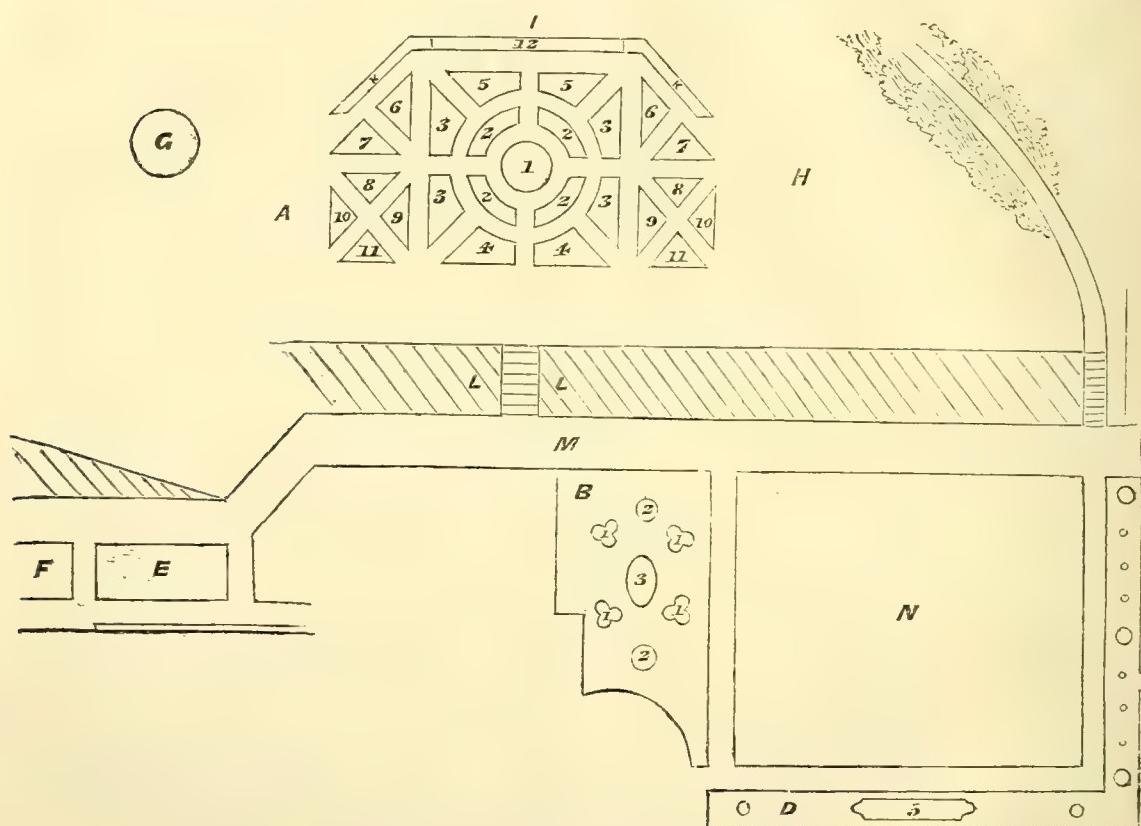

grown on what was a wild moor five years ago, and the ground behind this range is so still. The other houses are devoted to Peaches and Figs.

In front of these houses is the kitchen garden partly formed, and forming—no easy task where there is scarcely 2 inches of surface soil. The kitchen garden borders which had been formed, were planted with ribbon-rows, a practice very prevalent in this neighbourhood, and of which more anon. Fine dwarf Apple and Pear trees trained in the way they should go and already in good bearing, were arranged in the squares and borders.

On leaving the kitchen garden we enter the north court

which forms a large square, surrounded on each side by a neat low wall. Opposite the front door, on the north side of this, are a splendid pair of gates, once, we were told, the property of the great Napoleon, and bought at a fabulous price by Raikes Currie, Esq., the owner of this fine place, to whom it also owes its origin.

Behind these gates and away over the moor, among the heather, we could see the outlines of what would some day be a splendid avenue. On entering the pleasure grounds and flower garden we come first upon King Croquet's ground (N), in the shape of a sunk panel with plenty of space inside. Surrounding this, on one side, c, were large circular

FLOWER GARDEN AT MINLEY ABBEY.

- A. Beds in principal portion.
 1. Centre, Stella Geranium; next, Rose Queen; edging, Cerastium.
 2. Calceolaria Aurea Borbonica, Purple King Verbena; edging, Alyssum.
 3. Tom Thumb Geranium, edged with Mangelsii Geranium.
 4. Flower of the Day Geranium, edged with 'Verbena pulchella'.
 5. Brilliant Geranium, edged with Lobelia speciosa.
 6. Shrubland Rose Petunia, edged with Prince of Orange Calceolaria (old variety).
 7. Mangelsii Geranium, Verbena venosa, mixed; edged with Duke of Cornwall Verbena.

8. Imperial Crimson Geranium, edged with Mangelsii.
 9. Bijou Geranium, edging Lobelia speciosa.
 10. Old variegated Scarlet Geranium, edging Lobelia.
 11. Christine Geranium, edged with Mangelsii.
 12. Cerise Unique Geranium, edged with Gazania splendens.
 B. Four beds No. 1. Christine Geranium, edged with Lobelia speciosa.
 Two beds No. 2. Tom Thumb Geranium, edged with Alyssum variegatum.
 Oval bed No. 3. Pink Nosegay Geranium, Amplexicaulis Calceolaria, mixed; Scarlet Geranium edged with Cerastium.

- C. These nine beds are all pyramids, about 4 feet across, and from 4 to 5 feet high. Five of them are salmon and pink Nosegay Geranium mixed. The other four are Scarlet Geranium, with a white mixed in order to give life, the white Geranium Virginata.
 D. Circles, Trentham Rose Geranium, edged with Alyssum. 5. Tall Heliotrope and Geranium, Amplexicaulis Calceolaria, edged with Rose Ivy-leaf Geranium.
 E. Grass. K. K. Yew hedge.
 F. Conservatory. L. Grass slope.
 G. Rosery. M. Walk.
 H. Grass. N. Croquet ground.
 I. Terrace wall.

beds of pyramid Geraniums from 4 to 5 feet high. These have a splendid effect. It is surprising that we so seldom see this style of planting carried out. From here the view is magnificent; we are standing on a high point on a line of hills on one side, and opposite, against the horizon as far as the eye can reach, is a long range of the Surrey hills, with a wide-spreading valley, and Aldershot between, and a few gentle rising woody knots, on which here and there a noble mansion stands, the pride of all the neighbouring lands.

The beds in the flower garden were in fine bloom. A bed of Mangelsii Geranium and the old-fashioned Verbena venosa

were beautiful. There is too little of this mixing done. We tried the Purple King Verbena and Flower of the Day Geranium, once with the flowers picked off; but the venosa is a warmer colour and makes a richer bed. The whole is beautifully kept, and does as much credit to Mr. Meads as his fine Grapes. It must have been, literally speaking, uphill work to make this place in such a barren situation. The conservatory is small but well filled. Being an architectural structure, it is, like all of that class, ill-adapted for plants. The dells behind the house are being filled with American plants, which are best suited for heath soils.—J. F.

DINORBEN HOUSE.

IN times gone by it was usual to look for good gardening only in retired country places, where the smoke of factories and the dust of much-used thoroughfares never found their way, and when many gardening requirements, especially for forcing purposes, were only to be had in such rural retreats. Oak and Beech leaves for supplying bottom heat and subsequently furnishing leaf mould, were only to be had in quantity in places where they grew, and many other things wanted in a garden, as stakes of all kinds, were only to be obtained where grown. However, times have altered; the most bulky commodities are removed long distances with ease and economy, and the benefits of one neighbourhood are brought home to another. Facilities for gardening are now as much at the command of the suburban dweller as of those further removed; and we often see villa residences in fashionable neighbourhoods possessing all the requirements of country places of longer standing. A plot of ground of no great extent is made to combine park, pleasure ground, and garden; and the natural features of the locality being often judiciously blended in, the whole frequently presents effects that may be copied elsewhere. Amongst such suburban dwellings we now and then meet with some which claim a higher position alike for their extent and the taste and skill displayed in their management or arrangement. Conspicuous amongst these is that to which I now call attention, and which from its many artistic features will well repay a visit.

Dinorben House, the residence of — Reed, Esq., is beautifully situated on the slope of a hill a little distance from Tunbridge Wells. The site of the mansion is the side of one of those eminences which give the district around this fashionable town so richly varied an aspect. The house itself is new—in fact it may be said to be still in the builder's hands from the great number of workmen about it; but when finished it will no doubt present a noble aspect, and for many generations remain a monument of the taste of its founder. It is hardly my province to enter upon the architectural features, but I may state that the mansion is faced with Caen stone of the best quality, which, as every one knows, is the most suitable for the highest description of decorative work. I need hardly say that such has been largely introduced without at the same time running into any of the superfluities which defeat the purpose of ornamentation, and of which in the present age we have certainly many examples; but here a sufficiency of plain surfacing has been reserved to give solidity to the whole, while ornament where really wanted has been furnished with no sparing hand. The mansion, which faces the south-east, is approached from the contrary direction by a carriage road making a curve round the high ground at the back. The entrance-gates, which are very handsome, open from the high road leading from Tunbridge Wells to Pembury. The width of this road gives no little importance to the villas and mansions to which it affords access; while the scrupulous cleanliness of the whole, the salubrity of the air, the picturesque scenery, and, certainly not the least, the fashionable company by which the various tenements are occupied, all tend to give this district an appearance of wealth which only the higher class of watering-places present. The example set by the proprietor of Dinorben House has evidently had a great effect in inducing others to build in the same neighbourhood, and mansions of greater or less claims to notice are rising in various directions.

As I have just remarked, the mansion faces the south-east, and is sufficiently removed from the highway to secure the requisite degree of privacy. The ground at the back of the house, now in a transition state, will doubtless hereafter be rendered attractive by the many valuable trees removed there, Mr. Reed having for years been an extensive purchaser of fine specimens of Pinuses and other trees; and some good examples of successful transplanting were pointed out to me, amongst others was an Araucaria imbricata about 35 feet high, which had been three times transplanted in the last seven years. This, however, was not on the plot of ground alluded to, neither had the various removals which

the tree had undergone been beneficial to it, although its appearance was better than could have been expected in the case of a tree which had been so often subjected to such an ordeal.

Between the mansion and the high road is situated the kitchen garden, in which are some good, useful hothouses. The Grapes are particularly fine; in fact, I should say by the appearance of the Vines, that the soil of the neighbourhood seemed better adapted to their well-being than most of the mixtures that are compounded at so much cost elsewhere. A very short distance from Dinorben House is the garden whence Mr. Drummond sent some remarkably fine Black Hamburg and Muscat Grapes to the London shows two years ago, winning the first prizes in his class; and when I state that those at Dinorben House were scarcely inferior, I need say no more in their favour. The trees and other things in the garden were also good, and a conservatory adjoining the mansion was well furnished with flowering plants; but the principal feature of the place was the picturesque grounds fronting the mansion, and stretching a considerable distance to the right and left of it.

The mansion being on a ridge, the descent ends in a valley, the ground rising again on the opposite side. In this valley the spirited proprietor has at great cost formed a fine piece of ornamental water of some three or four acres in extent, and so contrived as to present a more natural appearance than most artificial sheets of water. A judicious disposition of trees and shrubs about it, with a very large amount of excavation, have rendered it as a whole as highly ornamental as its limited size will admit. The ground at the opposite side of the water has likewise not been forgotten in the liberal disposition of shrubs and trees, while the more dressed side nearer the house has been rendered highly interesting by the excavations and embankments, rendered necessary by the artificial damming up of the water, having been tastefully formed into rockwork. This has not been frittered away into whimsical combinations, of which we see so many examples, but has the more plain and solid appearance which natural scenery in an undisturbed state presents at places to our view, the only difference being in the class of plants which are grown. These consist of a liberal quantity of Pampas Grass, Cotoneaster, Juniperus, double Furze, on the higher and drier places, and many other plants, with some weeping deciduous plants overhanging the whole. In one of the groups I noticed a fine specimen of Aralia in beautiful flower, and as shrubs flowering in October are far from numerous, it would be well if those intending planting would secure plants of this pretty shrub, which, together with Ligustrum japonicum, and some others, form fine objects at this season. Returning from this digression, I may observe that the rockwork and its accompaniments formed a pleasing object by the edge of the water; and where this emptied itself into a lower level a waterfall was provided, and the water was subsequently conveyed through other channels to an artificial basin, forming a feature that will be described hereafter.

I have said that considerable addition is being made to the mansion, and numbers of workmen were busily employed. A large force was also engaged in removing earth immediately in front of the house, preparatory, I believe, to a terrace with balustrading, &c., being formed, and probably below this a geometrical garden, but of this I am not certain. Operations are going on over a considerable part of the space between the mansion and the shrubbery forming the screen-work to the rockery at the extremity of the lake. Eastward, however, of this there was a large space which had been planted some years, and the health and vigour of the trees told that the treatment they had received, had been to their liking. The natural inclination of the ground being to the south-east, an avenue of Deodar Cedars formed the extreme eastern boundary of the dressed ground in that quarter, the ground descending in a somewhat uniform fall of, perhaps, one in eight or nine, for about two hundred yards to the bottom, where a handsome basin received the water that passed from the lake above alluded to, which in some unsee-

manner entered and passed through the basin, keeping its water at all times pure and fresh. The basin also contained a piece of sculpture said to be of some artistic merit, and like others of its class, the fountain could be made to play from a supply furnished by artificial means, but without this its position, and the fine avenue of Deodars pointing to it, gave it a fine appearance. The ground rises on the opposite side from the basin, and the avenue ending there, a summer-house with another shrubbery formed a very good termination. The summer-house or grotto being slightly elevated, the rising ground with the two lines of fine trees looked remarkably well, while the mansion and sloping ground in front of it was also seen to great advantage.

From this point there was another walk skirting the other side of the pond. It was margined by shrubs, and had, I noticed, an edging of Berberis, or Mahonia, as it is often called. Some other walks in the same neighbourhood were edged with that very useful plant *Cotoneaster microphylla*, but I must not pass over the fine avenue of Deodars without again calling attention to it, and the adaptability of the tree for the purpose. Those here alluded to were nearly of uniform size and appearance, 15 or 18 feet high, perhaps, and in their present condition with the beautiful glade of turf between them (no gravel), they formed a feature that cannot well be too often copied; the only fault, perhaps, but which it is likely will not be found out for twenty years yet, is that the avenue is too narrow. Without measuring it, the width did not appear more than 45 feet, which might, perhaps, have done for *Wellingtonias*, or some deciduous tree intended to spread at top, but it is not sufficient for Deodars. A short time ago I saw a case of the same kind with Cedar of Lebanon, which had been planted about the same distance apart, and after a growth of about thirty years, they interfered very seriously with the gravel-walk between them, several of the branches meeting. Now this ought never to be the case with Cedars, as their beauty consists in our being able to survey them in their entirety, without mutilation of any kind. Nevertheless, for many years this will continue to be a noble avenue, and it, and the other fine trees of the choicest species of *Pinus* with which the lawn is interspersed, exhibit what skill and enterprise can do in a limited period. I believe the formation of the grounds, together with some other artistic work, is from the designs of Mr. Marnock, while the good keeping of the whole, where not invaded by alterations going on, reflected great credit on the worthy gardener, to whose kindness I am indebted for a sight of a place remarkable for the rapid progress it has made in the last few years, progress no doubt facilitated by the kindly nature of the soil. This seems to be of that intermediate kind which will grow American plants and other shrubs as well as trees. The influence of the climate has also, no doubt, something to do with it; but the great moving power no doubt is the persevering energy of the proprietor, who it is to be hoped may long live to see the perfection of objects of his own raising, and in his declining years witness the advance to maturity of many of those pets which all who are fond of out-door gardening surround themselves with, while another and another generation after that may look with admiration on the noble specimens of *Wellingtonia*, and other trees, and be told that these fine trees were planted, and the noble dwelling adjoining them erected, in the middle of the nineteenth century.—
J. ROBSON.

ROSES IN THE NORTH OF SCOTLAND.

It may be interesting to know how certain Roses succeed in this northern climate: I beg, therefore, to say a few words respecting some of the varieties I have in cultivation; but in the first place it will be as well to describe the soil and situation in which they are grown.

The ground is what may be called a good, free, working soil, of a darkish colour, rather light than heavy; the situation, chiefly for the sake of convenience, my time being limited, is in front of my cottage on a border facing the south, to which the ground slopes about 1 foot in 5. The soil is of good depth, and being on the gravel is naturally well drained.

Before beginning to particularise them I may state that, out of sixty or seventy varieties which are now growing in my small garden, and the whole of them were selected at random as far as their suitability for northern situations was concerned, I find that there are very few, if any, that will not do well with proper care and attention, especially if budded on the Manetti, and planted deeply. My young plants, none of them above two years old, produced blooms this season which were admired by all who saw them.

From *Gloire de Dijon* and *Souvenir de la Malmaison* (both in bud, with many others, at the present time), I cut blooms which measured 5 and 5½ inches in diameter respectively, without a faded petal, and with a freshness of colour I never saw surpassed in England, if, indeed, equalled; others were equally good, such as *Comtesse de Chabriant*, *William Griffiths*, *Madame Boll*, *Baronne Prevost*, *Madame Vidot*, *Anna Alexieff*, *Louise Odier*, and many others; amongst which the *Noisettes*, *Celine Forestier* and *Triomphe de Rennes* were most beautiful, although only planted last spring. The dark Hybrid Perpetuals *Souvenir de Comte Cavour* and *Triomphe de Lyon* did not do quite so well; although the plants were quite healthy, their flowers did not open freely. *Prince Camille de Rohan*, I believe, will prove a good Rose for the north; it is a fine grower, and in colour very rich and distinct: with me it was almost black. *Empereur de Maroc* and *Cardinal Patrizzi* have also done very well, as, indeed, have all the Roses in my collection with the exception of a few grafted plants, which I find are not at all suited for this locality, they may as well, and much better I think, be on their own roots at once. For instance: *Géant des Batailles* and *Lord Raglan* (the latter a strong grower), did not move at all the first year; the former has not yet produced a bloom worthy of its reputation; and last February I put in a plant each of *Colonel de Rougemont* and *Leon des Combats*, and up to the present time they have scarcely grown at all, while *Francis the First*, a Rose of moderate growth, has reached nearly 4 feet in height. Perhaps their slow growth may be attributed to their having been worked indoors at a high temperature, and sent out before being properly hardened off; but whatever the cause may be, they are useless, especially when rapid growth is an object.

Some of the others of my Hybrid Perpetuals have grown most luxuriantly, especially *Alexandrine Bachmeteff* and *Queen Victoria*; but the latter does not open well, which I fear may turn out to be the case with that fine Rose *Auguste Mié*, which I did not allow to bloom this season on account of the smallness of the plant; it is now large and healthy, having grown very rapidly. *Madame Louise Carrique*, *Jules Margottin*, *Victor Verdier*, and *Reine des Violettes* have grown finely; and *Duchess of Norfolk*, *Souvenir de la Reine d'Angleterre*, *Anna de Diesbach*, *La Reine*, *Senateur Vaisse*, *Buffon*, and *Dr. Bretonneau*, judging from the progress made by the plants, which were very small at the time of planting, I think will also do well, but the last is too dwarf in habit.

The Bourbon Rose *Paxton* is a very strong grower; but *Acidalie*, though I think it will ultimately succeed, has not yet shown any sign of being a vigorous grower, as most nurserymen describe it.

I have also a few summer Roses that have done remarkably well—viz., *Paul Ricaut*, *Coupe d'Hébé*, *Brennus*, *Chénédolé*, and the *Mosses Laneii*, *Comtesse de Murinais*, *Baronne de Wassenaer*, *Princess Adelaide*, a very strong grower, and *Celina*; the latter has grown pretty freely here, although generally described as dwarf. However much some people may fancy this Rose, I feel rather disappointed with it; its buds are pretty enough, but the flowers are only semi-double.

The Austrian Rose *Harrisonii* grows and flowers freely here, and is very beautiful, but the Persian Yellow will not open with me at all; I have it, however, budded on the Briar, and hope to see a flower or two next season for the trouble I have taken with it.

In addition to the above I budded, last year and this, some forty or more stocks of the Dog Rose, &c., from which I expect a fine display of bloom next season. Amongst the first-budded were two Roses I had given me by a neighbour the year before, which, on opening their flowers, I did not consider good enough to grow beside the other varieties.

I was about to take them up, and throw them away, when an idea struck me that I might turn them to account by converting them into standards of some other sort: I consequently budded one, a plant with a clean stem of about 15 inches in height, with Duchesse de Cambacères, and the other, about 3½ feet high, with Général Jacqueminot; the former from a dormant bud has this season grown into a fine bushy head, which produced no fewer than thirty-eight buds; and the latter, from a bud which was not much larger than a pin-head before starting into growth in the spring, has thrown up four strong shoots which have scarcely ceased blooming from July to the present time.

My reason for mentioning this is that from what I have seen I believe it will make an excellent stock, which the Dog Rose is not under all circumstances; for in light and dry soils, unless mulched or otherwise carefully attended to, it will not thrive at all. On the contrary, the Rose I speak of appears to do well in almost any situation; it grows and flowers freely in most of the cottage gardens in this neighbourhood, where it receives not the slightest attention. In colour it is of a rosy pink when nearly opened, but soon changes to a pale blush or white; flowers large and irregular in shape; in its wood and foliage it has some resemblance to the Moss Comtesse de Murinais. It does not, at least so far as my observation goes, throw up suckers at long distances from the root like the Dog Rose, which is a great advantage; for standards are frequently half ruined by these secret enemies before one is aware of their existence. I intend, however, giving it a further trial, having put in a dozen or two for budding on next season, after which I will be better able to judge of it.

Although the Rose, as you may have observed, is my especial favourite, I do not altogether forget the cultivation of other plants; but as your patience must now be nearly exhausted, I will merely state in conclusion that with various flowers, from the humble Crocus to the more stately Tulip and Gladiolus, with masses of Saponaria, Nasturtiums, Stocks, and Asters, I have contrived throughout the season not only to make one of the humblest cottages in the Highlands look cheerful, but, to a certain extent, comfortable by having the kitchen garden well stocked with various kinds of vegetables, including Scarlet Runners even, which are not known here as an article of food, a few nice rows of Celery, and some other things quite foreign to this locality. Being a young amateur, I feel some hesitation in forwarding these remarks; but the articles on the Rose which appear from time to time in THE JOURNAL OF HORTICULTURE, to which I am a regular subscriber, being chiefly confined to England, I do so in order to show that the queen of flowers, with a little care, can be grown, and grown well, even in our Highland glens. I regret, however, to state that, although such may be the case, cottage gardening in the Highlands is much neglected; a few Cabbages, Greens, and Potatoes are certainly from necessity grown, but in the cultivation of flowers the Highland cottager, generally speaking, takes no delight whatever.—LOCH NESS, Fort Augustus, Inverness.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE November meeting of the Entomological Society, held on the 7th inst., was very fully attended, in consequence of that evening being fixed for the presentation of a very handsome piece of plate (in the shape of an épergne representing a Palm tree with outspreading branches, the base clothed with foliage, amongst which insects were sporting), to William Wilson Saunders, Esq., F.R.S., Treasurer of the Royal Horticultural Society, &c., one of the most liberal patrons of entomological science. This piece of plate had been subscribed for by the members of the Society; and the address by which it was accompanied, engrossed on vellum, set forth Mr. Saunders's claims upon entomologists for his uniform liberality and devotion to the Society. Amongst the insects represented at the foot of the tree were several which had been dedicated by their describers to Mr. Saunders, such as the Erycina Saundersii, Mecynorrhina Saundersii, &c. Mr. Saunders, after expressing his gratitude to the members for so handsome a gift, impressed upon them the necessity of careful investigation into the habits and economy of the

objects of their study, and which had been too much neglected by entomologists. He had been anxious to forward exotic entomology by assisting in sending out collectors to foreign countries; but the collections which he had thus formed were freely open to any one desirous of studying them; and he should much prefer that the many new species which had thus been obtained should be described by our own writers rather than left for foreigners to publish.

Mr. Sidebottom exhibited four species of Beetles belonging to the family Curculionidæ new to the British lists—namely, *Lixus filiformis*, *Sibynes canus*, *Pentelus griseus*, and *Centorhynchus Poweri*.

Mr. F. Smith exhibited specimens of both sexes of a new British Bee, *Bombus pomorum*, taken near Deal, and which had been mistaken for a supposed variety of *Apathus rufipes*, but which proved to be a true species of Humble Bee.

Mr. Saunders exhibited some Galls found on rootlets of the Oak several feet underground, from which about a week previously wingless specimens of a species of *Cynips* made their appearance, all of which proved to be females. It was difficult to understand how these insects could either make their escape out of the ground from such a depth, or how they could find their way from the surface to the rootlets to deposit their eggs. It was also remarkable that the males were not developed at the same time, and it was suggested that this was a case of alternation of generations, such as had recently been pointed out as existing in the genus *Cynips* in the United States. Mr. Smith stated that, so far as his observations went, not a single male individual of the genus *Cynips* was known. The same was also the case with a species of *Tenthredo* (*Hemichroa Alni*), of which hundreds of females had been taken, but no male had ever been seen either in this country or on the continent.

Mr. Stainton exhibited a remarkable kind of Gall found on Oak trees, resembling a lump of cotton wool, of which, however, the perfect insect was not known.

Mr. Saunders also exhibited several other kinds of Galls, which he had found in Switzerland.

A series of engravings of British species of Hemiptera intended for a work on that order to be published by the Ray Society, was exhibited.

A letter was read from S. Stone, Esq., of Brighthampton, giving an account of the carrying out of diseased larvæ of Wasps by the perfect insects. He had observed this in nests of both *Vespa vulgaris* and *sylvestris*. He had also found the larvæ of the parasitic *Ripiphorus* in the nests of these insects, and had observed that the larvæ enclosed in the larger cells of the queen Wasps were larger than those in the small worker cells.

Professor Westwood suggested that the larvæ of the Wasps appeared to have been attacked by an epidemic similar to that in the hive Bee, described in these pages under the name of foul brood by Mr. Woodbury; and Mr. F. Smith gave an account of his visit to that gentleman, who had unfortunately rediscovered the malady in one of his hives.

Mr. Carter, of Manchester, exhibited several beautiful specimens of the very rare *Trochilium sphegiforme*, reared from the stalks of Alder in North Staffordshire.

The Secretary gave a very favourable account of the recent exhibition of natural history at Huddersfield, in which insects were well represented, amongst which was a remarkable hermaphrodite specimen of *Liparis dispar*. The exhibition had proved a complete financial success.

Mr. Baly read a paper containing descriptions of new species of exotic Plant Beetles (Phytophaga).

Mr. Wilson, of Adelaide, South Australia, sent an article containing a general survey of the entomology of our South Australian colonies as hitherto known. About five thousand species of Coleoptera had been captured, including 200 Carabidæ, 600 Curculionidæ, 450 Chrysomelidæ, 300 Bu- prestidæ, &c.

The Secretary read a translation of a memoir recently published on the natural history of a species of *Coccus*, which attacks the Sugar Canes in the island of Mauritius. In the discussion which ensued on this paper Mr. Saunders stated the very beneficial results he had found in the employment of diluted spirits of wine (one-half of water), for the destruction of Mealy Bug and other species of Coccidæ in greenhouses. Thus diluted it does not injure the plants,

and when applied in small quantities at the tip of a leaf it runs down the veins, in which especially are nestled the young of the Scale insects or Mealy Bugs.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Cabbages, hoe between the earliest-planted, and also between Lettuces, &c. This should be frequently done to growing crops throughout the winter, as by keeping the surface loose and open frost is prevented from penetrating to any great depth, and the roots are kept in a more active state. *Celery* may have a final earthing-up when the soil is dry, if the weather has prevented its being done before. *Cardoons* may also be treated in a similar way. *Leeks*, they should have more earth drawn to them before frost sets in. They are an excellent vegetable when well blanched. *Peas*, whenever the ground becomes dry put in a second crop of an early sort, as also Mazagan Beans. If Peas are sown in the open quarters the drills should be protected by a ridge of earth kept to the north or east of the rows. Keep down mice by trapping, they are troublesome to early-sown crops of the above. *Radishes* should be sown either singly or with the Short Horn Carrot on a dry warm border in beds. The Early Frame or Short-topped is best at this time. Cover the beds with straw or litter till the seeds germinate, when they should be uncovered every day when not frosty. *Sea-kale*, the old plan of forcing Sea-kale was a most expensive and unsatisfactory mode, expensive on account of the breakage of pots, and the loss of labour, and unsatisfactory on account of the want of more perfect control over the whole proceeding. The best as well as the most economical plan is to take up the roots and force them in a body, after the manner of Asparagus. To accomplish this, it is of course necessary to grow the roots strong, for the especial purpose, and in the kitchen garden. Such roots being available, they may be forced in any structure from which light and the severity of the weather are excluded. The roots can be either forced in frames with a double mat nailed down over the glass, or under the mere wooden box; but the best place is the Mushroom-house. A sunken pit is necessary, and this should be a yard in depth—that is, 2 feet for the fermenting material, and 1 foot or nearly so, for the crowns to rise, with any opaque covering considered necessary. The strongest fermenting material is placed at the bottom, with a slight covering of old leaves, the crowns are set thereon as thickly as they can stand, and filled up between with old tan. If at the beginning the heat is too strong it is reduced by the application of cold water, repeated if necessary, and when the crowns are 3 inches long all the remaining bottom heat is done away with by the application of cold water; this renders the Kale stronger, and retards it for succession. Rhubarb may be forced in a similar way. This, however, may be placed in large pots, and set on flues or other warm surfaces. Asparagus requires the same treatment, but it should have 4 inches of soil over the crowns, for if the stalks be long exposed to a low temperature, they will be hard and of inferior flavour.

FRUIT GARDEN.

Where orchard trees have been left for some years unpruned, the hand-saw will be required to thin out the larger branches. Keep the middle of the trees open to admit air, and to promote the formation of fruit-buds on the interior branches. It is, however, a bad practice to leave any description of fruit tree to itself, as it would in all cases pay the cultivator to prune once a-year at least. Push forward pruning, nailing, and tying espalier trees, and suchlike tedious operations, as fast as the weather and circumstances will admit.

FLOWER GARDEN.

Let lawns be well rolled when sufficiently dry for the purpose. Every part of the turf should be frequently swept during the winter. Nothing adds so much to the enjoyment of pleasure-ground scenery as well-kept turf, and when connected with evergreen shrubs an agreeable relief to the dreariness of the season is afforded, which renders the loss of more attractive plants less to be regretted. At the same time see that the walks are kept dry and firm, in order that they may at all times be comfortable to walk upon.

STOVE.

This will require a very liberal ventilation now, increasing fire heat, if necessary, in order to accomplish it. Still apply moisture to the air, although in a diminished degree; but withhold moisture entirely from the roots of deciduous Orchids, or those sinking into a state of repose. If there is any fear of a scarcity of bloom next May, a portion of the Achimenes and Gloxinias should be repotted at once, and placed in a warm part of the house, choosing such as have been longest at rest; and a few Clerodendrons, Allamandas, a plant or two of Echites splendens, and Dipladenia crassinoda, may also be started. Let Ixoras and all other hard-wooded plants that have made sufficient growth, be kept rather dry at the root, in order to check their growth, and induce a tendency to form bloom-buds, but do not let the soil in the pots become so dry as to affect the foliage.

GREENHOUSE AND CONSERVATORY.

Should dull weather continue, occasional fire heat will be required for the plants in these houses. The fires should be lighted in the morning, in order that the houses may be thrown open during the day to promote a free circulation of air. This will dry up damp and help to keep the plants in a healthy state. Let the surface soil of the pots be slightly stirred to remove moss and promote free evaporation from the surface.

PITS AND FRAMES.

With the assistance of a garden frame, and some stable manure or tan to furnish a gentle heat, Hyacinths may be had in flower at Christmas, and with a good stock of bulbs the display may be kept up till April or May. For early forcing the bulbs should be planted in September, as recommended at that time; those to flower in spring should be planted in October, November, and December. The best pots are the 48-size for one bulb, and the 32-sized pot for three bulbs. It may be well to add that three bulbs grown together in one pot produce a much finer effect than single bulbs. The soil should be one-half fresh loam, decomposed horse or cowdung, with a small portion of clean sand well intermixed. If, however, this cannot be obtained, then the lightest and richest at command must be employed instead. Fill the pots lightly with the prepared compost, and place the bulb upon the surface, slightly pressing it into the soil. After giving a liberal watering set the pots out of doors on a place where perfect drainage is secured, and cover them with about a foot of old tan. After remaining there about a month or five weeks the bulbs will be sufficiently rooted to render it safe to remove them to a gentle bottom heat of about 55°. It is necessary to be careful that the roots are not allowed to penetrate the fermenting material. A sitting-room window forms a suitable situation for Hyacinths while in bloom, and the beauty will there be longer in fading than in most places.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Tried to clean it up a bit, but the dripping weather prevented us doing more than clearing the walks of leaves; taking up Asparagus for an early bed, filling merely one light at first, as we have rather encroached on our stock in previous years, and must dispense with having it so early for a year or two, until the stock fit for forcing is larger.

Artichokes, Globe.—Cut over the stems, and placed some long litter over each stool, and then a few spadesful of soil over it to keep it in its place. It is safest to give these this little protection, especially in heavy soils. The assurance of their hardiness will be a poor compensation for the want of a supply if, from trusting to that assurance, the plants should be killed by a severe frost. We have known them stand uninjured and unprotected for several years, and then, after another season, not a bit of the old plants was left alive.

Sea-kale.—Took up a lot, squeezed the roots into pots, and placed them in the Mushroom-house. It would be easier to place them in a bed at once; but placing the plants in pots permits of their being moved as desirable, either into a little bottom heat, into a cool dark place when

the heads might incline to come faster than we want them. Other vegetables much the same as in the two previous weeks.

FRUIT GARDEN.

Took most of the Strawberry plants in pots under cover in the orchard-house. Placed some in frames with a little bottom heat, just to give the plants a start, and yet, by giving plenty of air, prevent anything like drawing the crowns. These pots are merely set on the bed in reduced leaves, a foot thick of fresh leaves being beneath them; but we would have preferred the pots to have been either suspended or set on a hard bottom, as shelves, &c., at first, as whatever will tend now to produce vigorous foliage will also tend to rob the flower-buds of their strength. Having no nice airy house at liberty, we do not now desire Strawberries very early. We have had them very tidy to look at at Christmas and on New Year's-day; but unless the weather was frosty and a bright sun, there was little flavour in the fruit. In bright weather, and from keeping the pots rather dry for some days before gathering, the fruit was very tolerable.

Pruned some more Peaches, and looked over Grapes in vineries, and fruit of Apples, Pears, &c., in the fruit-room, as this dull muggy weather is the worst for fruit-keeping. We think if the shelves and drawers are clean nothing should be used to set the fruit on except well-dried paper. Straw, hay, &c., always give more or less of a taint whenever they become a little damp. In this dull weather a pretty free ventilation should also be given, or the place will become too damp and confined, and the fruit in consequence will sweat and rot. A few rotting fruit will contaminate the whole house, and all such should therefore be removed. Fruit spotted with the first marks of decay should either be used at once or given to the garden men, as in a short time they will be fit for nothing.

Except in some of our large places, as Trentham, Enville, Luton Hoo, Wrest Park, &c., it is rare to find a suitable fruit-room. Any shed or out-of-the-way place is made to answer. Much may be done in the most unsuitable places if there is a proper amount of earnest enthusiasm; but even enthusiasm will die out if there is nothing with which to feed its fire. We knew of a case in which a bachelor gardener saved the crops of some Peach trees for two years in a severe frosty night by each time getting out of bed, and taking the whole of his bedclothes to act as coverings to the trees. No other means being in future procurable, and as the proprietors objected to even the appearance of branches, our old *confière* at last cooled in his enthusiasm, and the next year the frost settled the young crop. That was not the worst of it. We have no doubt that the use of the bedclothes for the above purpose, however commendable as an effort of anxious enthusiasm, laid the foundation of our old comrade's last illness. That is not the only instance in which gardeners to our knowledge have injured their health for life from an excess of otherwise most commendable zeal and anxiety. To secure good winter fruit for table, and to see it comfortably before it goes there, a good place, hollow-walled, hollow-roofed, and yet air and ventilation at command, ought to be secured.

Fig-house.—The fruit now becoming very insipid, we had all removed that was larger than a pea, pulled off any leaves that were left, gave the plants a fair thinning, as we grow them roughly in the bush style, washed them over with soap and water, and then painted with clay, sulphur, and a little Gishurst mixed. We have not washed these Figs for several years, as we never noticed anything on them; but this season we saw some scale, and we would rather have it all destroyed before the plants come into leaf than afterwards. Prevention is ever better than cure; and most likely if we had washed the trees last season we would not have had this incipient appearance of insects now. We immediately watered the plants to prevent the roots becoming overdry in winter, and then filled the whole bed with bedding plants, and gave plenty of air to keep the house cool, which will be continued until we give more heat to start the Figs. After many trials and some experience we have given up allowing a Fig to stand over the winter that is much larger than a pea. Those just swelling at the base of where the leaf was are still more sure. Did we want to bring in our ripe Figs early in spring we would have effected this thorough clearing by October,

as we have long proved that the longer Figs are allowed to bear in autumn and the beginning of winter the more apt are they to drop their fruit next season.

Singleton, or White Ischia Fig.—This dropping of the first crop is very characteristic of the Bacifico, the Singleton, and the White Ischia, all of which we believe to be *aliases* of each other. There is not a better nor sweeter Fig than this little honeycomb of a thing, which in general is not much larger than half the size of a good White Marseilles; but to have it good and well ripened, and opening itself up like the half-expanded flower of a Stapelia, requires a good heat. We mention this the more particularly because, though we have had a fine warm summer, we did not ripen this Fig well in an orchard-house, and kept them too long there to ripen kindly in a closer and warmer place afterwards. It is true we were rather deficient of water during the summer, but we do not think that was the cause of not ripening kindly so much as the craving for a closer and warmer atmosphere. Such kinds as Lee's Perpetual or Brown Turkey, and even White Marseilles, ripened kindly enough, the latter two crops and a portion of a third; whilst this little thing did not ripen one crop comfortably. We cut off great batches of fruit from small pots, because there seemed no chance to their ripening kindly. In a viney or in the Fig-house, where a little artificial heat was used, they ripened kindly, and bore profusely. We mention this the more particularly because we have a little doubt if the questionable liquid we were forced to use suited this rather delicate Fig over-well, though not hurting other Figs; and, therefore, we should be glad to know if others this season have fruited this kind to their minds in an open, cool, unheated orchard-house. To make the Singleton yield a good first crop in April May, &c., it should be pruned, and all the fruit on it removed before the end of September. Without such precautions it is so apt to throw off its first crop, that it would be best to prune it, and treat it to yield only one crop in the year. This one crop in the orchard-house ripened very unsatisfactorily with us this season.

ORNAMENTAL DEPARTMENT.

As the weather permitted, got on with cleaning beds, &c., regulating herbaceous plants, faggotting old Scarlet Geraniums in pots, and shallow boxes, examining all young stuff, to prevent damping, taking off each leaf that showed any signs of such visitation, giving the plants more room, stirring the surface soil, and carefully watering any plant that seemed dry, so as not to damp the place. Thinned creepers in conservatory, gave manure water to Chrysanthemums, Primulas, Cinerarias, Pinks, and Perpetual Carnations, and to other things that needed it. As some damp has been caused by previous washing and cleaning, put on a brisk fire in the daytime, with plenty of air to dry the house, giving air to hardwooded plants, however, as detailed the other week. Placed Roses in pots in a little bottom heat. It is amazing how these plants flourish in a cool temperature with a slight increase of bottom heat, and the pots plunged in a bed, even if the bed is old sawdust. All hardy shrubs force nicely into bloom when thus helped. See what was lately said about looking after bulbs of all kinds. Thinned out very much the creepers in the stove to give light, and removed all the autumn Gesneras, &c., to the floor of a cool house, where frost will not reach them. Removed also the pots of Caladiums to the floor of a cool stove, and covered them over with moss, which will prevent them becoming over-dry, and otherwise we will let them get pretty dry, but not quite so. All the Amaryllids, Tritomas, &c., that are now resting, will receive moisture enough if the pots stand on a cool moist floor in a house where the temperature is rarely under 40°. In such dull, foggy weather, damp, and weak, sickly growth must be neutralised by plenty of air, and a low temperature, and if possible a drier atmosphere than that which prevails outside our houses.—R. F.

TRADE CATALOGUE RECEIVED.

B. S. Williams, Paradise and Victoria Nurseries, Holloway.
—Catalogue of New and Choice Pelargoniums, New and Rare Exotic and other Plants.

COVENT GARDEN MARKET.—NOVEMBER 26.

The supply of out-door fruit continues plentiful, and consists of the same varieties as mentioned in previous reports. Winter Nels Pears have made their appearance this week. Of Grapes there are sufficient for the demand; of Pines there is a better supply, and prices have somewhat declined. Oranges and Lemons are now coming in more freely. All out-door vegetables, such as Cabbages, Brussels Sprouts, and Savoys, are sufficient for the demand. Potatoes are abundant, but rather dear; and Onions have also increased in price, though some consignments have come in from Germany.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

TRITONIA AUREA CULTURE.—I advise all those interested in this plant to try both systems—viz., that of Mr. Abbey and that I advocate, and to judge for themselves. I never found Tritonia aurea in a state devoid of growth, or leaves more or less green.—W. EARLEY, Digsowell.

GRASS-LAND MANAGEMENT (Miles).—The best work on the Grasses, and giving some instructions for the improvement of meadows and pastures, is Sinclair's "Hortus Gramineus Woburnensis." There is also a good essay on the economical improvement of Grass lands in the seventh volume of the "Quarterly Journal of Agriculture."

SELECT CHRYSANTHEMUMS (P. J. H. D.).—Of Tasseled flowers, Triomph du Nord, reddish chestnut; and Invincible, white. These are the only two which we can recommend to you. For twelve good incurved kinds have Jardin des Plantes, Cherub, yellow; White Queen of England, Beverley, white; Lady Hardinge, Lady Slade, Her Majesty, Bella Donna, rose and blush; Sir Stafford Carey and Lord Ranelagh, brown; Prince Albert and Dr. Rosas, crimson. Six Pompons—Fairest of the Fair, Madame Fould, Danæ, Salomon, Capella, Madame Eugène Domage.

WINTERING COLEUS VERSCHAFELLI (J. T. O.).—The large bay window is preferable to either cold frames or the window with a north aspect. Keep the soil dry, giving no more water than is sufficient to prevent the stalks shrivelling. It will not bear much cold, and not the least damp, and requires a temperature of 45° to winter it safely. You may winter it, however, by keeping it dry, and excluding frost by heating the room either with a lamp or hot water, the latter being preferable. It should not be cut down now, and not in spring until it commences growing afresh. "Florist's Flowers," which may be had free by post from our office for five stamps, contains the information sought.

AZALEA AMENA POTTED IN LOAM (J. M.).—We have grown Azaleas very fairly in loam and leaf mould, and we think your plant will also do well until the blooming is past, when we would pot it in peat soil. It is only natural for the leaves to turn yellow and fall, though more have fallen than we should like at this season. Ours are remarkably fine in foliage this year.

BRITISH FERNS FOR EXHIBITION (A Young Gardener).—Lastrea Filix-mas cristata, Polystichum angulare proliferum, Athyrium Filix-femina plumosum, Scolopendrium vulgare multifidum majus, Asplenium trichomanes incisum, Blechnum spicant ramosum. Take the Strawberries under cover at once, and by the beginning of January place them on shelves near the glass in a viney at work, bringing them on slowly.

THREPS ON FERNS—CLIMBERS FOR A CONSERVATORY—WHITE HELIOTROPE (*Flora*).—On a calm evening fill the house with tobacco smoke by burning shag tobacco in a fumigator, and repeat the dose on the next night but one. Fumigate afterwards whenever a thrips is seen. Our correspondent wishes to know how to preserve Arbutus berries, so as to use them as an ornament for dishes. As to creepers for a conservatory, no mention is made as to how many are desired. Lapageria rosea, Mandevilla suaveolens, Mimosa prostrata, Passiflora Neumannii and Clowesiana, Hibbertia grossulariaefolia, Jasminum heterophyllum, Soliva linearis, Tasconia mollissima, Kennedya monophylla, and K. rubicunda superba, are all suitable. We know of no shrubs that will thrive in extremely wet soil without drain ge except Willows, Alder, and bog plants, and not one in a hundred are shrubs. So far as we know, a white Heliotrope is not now to be had. H. linifolium, from the Cape, we have grown, but thought little of it. Most of the white kinds are annuals and biennials.

VINES FOR GREENHOUSE—FERNS FOR GLASS CASE (M. P.).—You will require five Vines if they are planted along the front, the first one being 1 foot 6 inches from the end, and the others 3 feet apart. You may have Black Hamburgh, Buckland Sweetwater, Black Champion, White Fron-tignan, and Trentham Black; but we would only have three in so narrow a house, and plant in front a Black Hamburgh 3 feet from the end of the house, Buckland Sweetwater in the centre, and Trentham Black 3 feet from the other end. When they reached the rafter we would let two shoots grow, and train one to the right and the other to the left, and up the house when each had run 1 foot 6 inches. In this case you would have rods at 1 foot 6 inches from the ends, and a little less than 3 feet apart, just the same as if five Vines were planted. You may have either British or exotic Ferns, just as the situation is cold or warm. Say British—Lastrea Filix-mas crispa; Polypodium vulgare, P. vulgare auritum; Scolopendrium vulgare, and the varieties sub-cornutum, ramosum, marginatum, and multiforme; Blechnum spicant ramosum, and B. spicant lancifolium; Asplenium marinum, A. septentrionale, A. viride, and the multifid form (bifidum or multifidum), A. trichomanes, and varieties multifidum, incisum, and depauperatum; Adiantum capillus-Veneris; Asplenium fontanum; Polypodium cambricum; Polystichum lonchitis, and P. angulare proliferum. Exotic Ferns—Asplenium moehringianum, obtusum, reclinatum, radicans, dimidiatum, fabelliforme, and attenuatum; Adiantum reniforme, setulosum, affine, and cuneatum; Davallia canariensis, pentaphylla, desora, and solida; Lastrea glabella, acuminata, and quinquangularis; Acrophorus Novae-Zelandiae; Nephrolepis rupestris, pertusa, and lingua; Nephrolepis tuberosa, and pectinata; Drynaria Fortuni; Platyloma rotundifolium; Pleopeltis pustulata, and stigmatica; Pteris cretica, serrulata, cretica albo-lineata; Woodwardia (Doodia) aspera, media, and corymbifera or candata; Selaginella densa, and S. dentata, for surface.

RIDGING LIGHT SOIL (K. R.).—Your gardener is probably correct. Ridging light soil, and exposing it thus to the frosts of winter, has little or no enriching effect, but it confers a benefit by destroying the larva of vermin, if the frost is intense. Your best culture would be to grow your Turnips, &c., in narrow beds, deepening the soil of these by throwing on to them the earth from the paths, and mulching your crops with cocoa-nut fibre refuse and other material.

CASE FOR STRIKING CUTTINGS (A. P. D., Salop).—The Bijou Plant Case made by Mr. Stock, Archer Street, Westbourne Grove, answers. It is heated either with gas or Child's night lights.

MUSHROOM-GROWING (A Reader).—See an article on this subject by Mr. Fish in No. 169. It is just the old concluded story repeated. Place spawn in the ground anywhere, and prevent it being lost there by heat and moisture, and it will produce Mushrooms without any chemical waterings; but such spawn will soon exhaust itself. To secure a good lasting bed the spawn must run in rich manurial matter. The article referred to, and "Doings of the Last Week," will tell you more than we can well repeat now. We have no faith in such short cuts to success. We have had plenty of Mushrooms in the open air by merely placing bits of spawn below the ground an inch or so, but they were soon exhausted. All the chemical waterings, &c., are mere theoretical delusions.

VINES IN POTS (E. S.).—Any kind of Vines may be grown in pots in a viney. For an orchard-house, Black Hamburgh, Royal Muscadine, Dutch Sweetwater, and Buckland Sweetwater, are perhaps the best. See remarks of Mr. W. Paul the other week. Plants in pots and in the open ground are in different circumstances. With Vines you may keep the soil in the pots open until they are placed in the fruiting-pots. After that, and when starting for fruit, the soil should be firm. When mere growth is the object keep the soil open: when fruitfulness is the object keep it firm.

SHRUB FOR A GALLERY (M. D.).—You say nothing at all about the sunlight, the most important circumstance. Gaslight is prejudicial to plants, unless nicely managed as to ventilation. No plants will flourish long without the light of day. If, as we presume, you are without that light, the only thing you can do is either to grow large plants of Geraniums, keep them in the gallery for a few days, and then replace with others, taking them in and out. Shrubs, such as Acerias, Laurels, and Cypresses, may be treated in the same way. If you have light any shrub will succeed.

SULPHUR PAINT FOR FRUIT TREES (C. P.).—Sulphur and clay is a capital paint, and you may add a little lime, but not much if the lime is fresh. If the lime is mild it will have little more effect than any other earth, and we would prefer a little soot instead. The main object is to shut up all the buds and wood from the air for a time. We would decidedly paint the trees, though they showed no signs of insects during the summer, doing it chiefly all about the buds with a soft brush. Prevention is better than cure. We have not painted our Figs for several years, and saw nothing until this autumn, when we noticed scale. We washed with soap water, and then painted with clay, sulphur, and a little soap in the water. As the buds swell the mixture will drop off, and you can help it gradually by slight syringing.

VINES—PEARS ON QUINCE STOCKS (W. E.).—The "Vine Manual," which you can have free by post from our office for thirty-two postage stamps. The point of union of the scion and the Quince stock should be buried beneath the surface of the soil.

CAMELLIA BLOOMS FALLING WHEN HALF-EXPANDED (J. M.).—We think that the temperature was too low, and that if there had been an increase of heat sooner they would not have fallen. They remained a fortnight half-expanded, and then you gave an increase of heat sufficient to have thrown off the buds of anything. A rise of 10° in so short a space of time must be injurious to vegetation. We are not certain, but incline to the opinion that the buds were not fully matured, and the imperfection did not manifest itself until the blooms commenced expanding.

REPLANTING FERNS IN ROCKWORK UNDER GLASS (A. B.).—The best time to replant them would be in the March of next year, but you may do so now if care be taken to remove them with as much root as possible.

SOWING INDIAN SEEDS—COVERING VINE-BORDER (W. M. B.).—Sow the seeds in March, and place the pots in a hothouse of from 75° to 85°. The vine-border would be improved by covering with a good thickness of dry leaves or litter, but not such as would heat much. This covering would prevent the border becoming very wet, as the materials would themselves absorb most of the rain. If not covered in this way, it ought to have at least a six-inch covering of litter to prevent frost injuring the roots. Your covering up well the border with leaves and dung a short time before commencing to force is good.

GLASS FOR VINEY (Calcareous).—It is against our rules to address our coadjutors privately. Mr. Abbey is not a plant-seller. We question if you could get the plants spoken of in any one nursery at present; but if you make your wants known you will obtain them all by degrees, and as soon as the demand is known there will be no want of a supply. The 16-ounce glass will do if about that weight; but if some of it does not range above 13 ounces it will be scarcely strong enough, as your rafters are 20 inches apart. We believe that in a box of some hundreds of feet you will find little that is fully 16-ounce, though called so. Some may be a little more, but the bulk will scarcely average 15 ozs. The squares should not be deeper than 12 inches at most—that is, 20 by 12. Twenty by ten would be better, as the laps give strength. If the place is exposed, however, we would advise what is called 21-ounce, though it would cost some £1. 3d. more. We have used 16-ounce ourselves, and, as yet, with little or no casualty for a number of years; but we think that were we doing much again we would prefer 21-ounce, as the squares bend a little in storms, and especially with snow. With hail we think the bending is no disadvantage.

GARDEN PLAN (A Subscriber, Ramsgate).—The only improvement in your plan that we would suggest would be to do away with the stiff shield-like piece of grass in front of the house by curving it on each side, either by taking it nearer the wall, or farther from the wall about its centre, and the same beyond A, either of which would do away with the stiffness and make it more picturesque. The quickest-growing evergreens would be the common Laurels; but if you are far enough from the smoke we would advise them next the wall, and to be cut out as they grew too large, and then a mixture of Cypresses, Abies, Vita, Arbutus, Portugal Laurels, and Aucubas, and Laurustinuses for the front row. If on the turn of the walk you came near the wall, you could drape it with Ivy. If the soil is poor enrich it with rotten dung; if little better than sand or clay you will have to add some loam or good soil from a field or the sides of the highway. A few deciduous shrubs, as Lilacs, Ribes, and Spiræas, would enliven the borders.

CARROT CROP FAILING (George Wighton).—To guard against the ravages of the Carrot grub, we trench the ground 2 feet deep in November, working in a liberal dressing of well-rotted manure, and throwing the surface in ridges and as rough as possible. We throw it back or down on sharp frosty mornings in February, and in March a dressing of lime is applied. At the time of sowing the ground is strewed black with soot, not pointing it in like the lime with a fork, but covering it with the soil from the alleys between the beds. The seeds are then sown in drills in the usual way, and we invariably have a splendid lot of Carrots in autumn.

CHICORY DRYING (D. Applegate).—Mr. G. Abbey writes, "I gave that part of Chicory treatment which related to its cultivation and preparation for market, and it is not usual for cultivators to enter on manufactures." Of the drying process, he says he is "practically ignorant."

ROSE SEED SOWING (Rosan).—Gather the hips when fully ripe, as they will be by this time, and place in a flower-pot in dry sand, guarding against mice which are very partial to them. In the first week in March break the hips into pieces and sow them in pans, but these should not be common seed-pans, which are about 3 inches deep. Those for Rose-seeds should not be less than 6 inches, and they need not be more than 9 inches in depth. Good sized flower-pots will do quite as well. Drain well, and fill to within 1 inch of the rim with rich sandy loam, on this place the seeds about 1 inch apart, and cover with half an inch of fine soil. Plunge the pot outside quite up to the rim in a sunny open place, watering so as to keep the soil moist; but this will only be needed in dry weather. The young plants will probably appear in April or May, but the seed may not vegetate until the second spring. Strict guard must be kept against mice, or they will take them all. When the young plants have made three or four leaves take the plants up carefully and pot them in small pots, placing in a cold frame for a few days then harden off, and plant out a month later in a bed of rich soil. By the end of August they will have made shoots strong enough for budding, especially the strong growers, take these and bud on strong stocks. The following summer the buds will make vigorous growths, and they being left unpruned will bloom in the following year. If not budded let them grow without pruning, but most of the better varieties are shy bloomers on their own roots. They will bloom, many of them without working at three years old, but it usually takes six years to bloom a superior sort on its own roots, for they are mostly vigorous, at least, we want such for our climate. We fear that the horse-droppings would emit an unpleasant smell, but we recently saw the bottom of a closet turned into a mushroom-bed, and it was producing famously.

—G. A.

NAMES OF FRUIT (D. J.).—1, Duchesse d'Angoulême; 2 and 3, Beurré Bois; 4 and 5, Vicar of Winkfield; 6, Achan; 7, Comte de Lancy; 8, Beurré Blanc de Capucins; 12, Beurré Diel; 13, Uvedale's St. Germain; 14, Beurré Langeler; 15, Baronne de Mello. (C. R.)—The Apples are—1, Catshead; 2, Ribston Pippin; 3, Herefordshire Pearmain; 4, Claygate Pearmain; 5, Pearson's Plate; 7, Lewis's Incomparable; 9, Golden Pippin. The Fern is Asplenium adiantum nigrum, var. acutum. (H. T.)—The Pear is Besi d'Her. The pale Apple is White Winte Calville, and the red one we do not know.

NAMES OF PLANTS (Louisa).—The Arabis sent is the Lucida variegata. We think the white variety. Of variegated Arabis there is also a yellow-tinted variety, but the colour was too faded to know whether the leaves had been edged with white or yellow. The succulent having no flowers we are

unable to point out. It looks like a low-running Sedum with small green foliage edged with white; but it might also be a Mesembryanthemum. We regret we cannot be sure. (A. T.)—Neither of the shrubs are nameable without flowers. The Ferns are—1, Adiantum Æthiopicum; 2, Nephrolepis tuberosa. (Worcestershire Subscriber).—1, Unnameable in its present state; 2, Adiantum sp.; 3, Anemidictyon phyllitidis; 4, Platyloma rotundifolia. (Ruby).—The Polypody is the variety called cambricum; the other Fern is Lastrea spinulosa. You must send a better specimen of the Fuchsia. (Coniferous).—How can you expect us to name such scraps? We can only guess at what one or two may possibly be. 1, Is the tip of the frond of a Blechnum; 3, A Thuja, perhaps occidentalis; 4, May be Bota orientalis; 5, Looks something like a bit of Taxodium distichum; 7, Quite unrecognisable.

Poultry, Bee, and Household Chronicle.

BIRMINGHAM POULTRY SHOW.

THIS Exhibition commenced yesterday, and will be continued until the 1st of December is passed. We have only time to print a list of the prizetakers. Our remarks, as well as the list of commendations, must be reserved until next week.

DORKEINGS (Coloured).—First and Third, Right Hon. Viscountess Holmesdale, Linton Park, Kent. Second, Sir J. Don Waughope, Bart., Miller's Hill, Dalkeith, N.B. Fourth, T. Tatton, Kingthorpe, Northampton. Fifth, T. Statter, Stand Hill, Manchester. **Chickens.**—First and Second, Capt. W. Hornby, Knowsley Cottage, Prescot. Third, Sir St. G. Gore, Bart., Hopton Hall, Derbyshire. Fourth, R. P. Williams, Glaslawn, Clontarf, Dublin. Fifth, J. Frost, Parham, near Wicken Market, Suffolk.

DORKING HENS.—First, W. W. Bartham, Henley-in-Arden. Second, Right Hon. Viscountess Holmesdale, Linton Park, Kent. Third, J. Drewry, Newton Mount, Burton-upon-Trent.

DORKING PULLETS.—First, Capt. Hornby, Prescot. Second, R. W. Boyle, Dublin. Third, Rev. E. Cadogan, Walton Parsonage, Warwick.

DORKINGS (White).—First, J. Robinson, Vale House, near Garstang. Second, H. Lingwood, Suffolk. **Chickens.**—First and Second, H. Lingwood, Second, H. Lingwood, Suffolk.

SPANISH.—First, H. Lane, Bristol. Second, J. Garlick, Liverpool. Third, Rt. Hon. the Viscountess Holmesdale, Linton Park, Kent. Fourth, R. Teebay, Fivewood, near Preston. **Chickens.**—First, E. Jones, Clifton, Bristol. Second, D. Parsley, Bristol. Third, E. Brown, Sheffield. Fourth, R. Teebay.

SPANISH HENS.—First, Miss Biggar, Ecclefechan, Dumfriesshire. Second, Rt. Hon. Viscountess Holmesdale.

SPANISH PULLETS.—First, Rt. Hon. Viscountess Holmesdale. Second, H. Lane, Bristol.

COCHIN-CHINA (Cinnamon and Buff).—First, Capt. Heaton, Manchester. Second, C. T. Bishop, Lenton, near Nottingham. Third, H. Bates, Yardley, near Birmingham. Fourth, R. Adams, Handsworth, Birmingham. **Chickens.**—First, Capt. Heaton, Manchester. Second, T. Stretch, Ormskirk. Third, Rev. C. Spencer, Attleborough, Norfolk. Fourth, C. T. Bishop.

COCHIN-CHINA HENS (Cinnamon and Buff).—First, E. Smith, Middleton, near Manchester. Second, Capt. H. Heaton, Lower Broughton, Manchester.

COCHIN-CHINA PULLETS (Cinnamon and Buff).—First, H. Yardley, Market Hall, Birmingham. Second, T. Boucher, Birmingham.

COCHIN-CHINA (Brown and Partridge-feathered).—First, J. Shorthose, Sheldfield Green, Newcastle-on-Tyne. Second, J. Stepeas, Walsall. Third, Cartwright, Oswestry. **Chickens.**—First and Third, T. Stretch, Ormskirk. Second, R. White, Broomhall Park, Sheffield.

COCHIN-CHINA HENS (Brown and Partridge-feathered).—First, E. Smith, Middleton, near Manchester. Second, T. Stretch, Ormskirk.

COCHIN-CHINA PULLETS (Brown and Partridge-feathered).—First, —Cartwright, Oswestry. Second, E. Tudman, Ash Grove, Whitchurch, Salop.

COCHIN-CHINA (White).—First, R. Chase, Balsall Heath, Birmingham. Second, Rev. F. Taylor, Keastwick, Kirkby Lonsdale. **Chickens.**—First and Second, Rev. F. Taylor, Keastwick, Kirkby Lonsdale.

BRAMHA POOTRAS.—First, Mrs. Hargreaves, Arborfield Hall, near Reading. Second, R. W. Boyle, Dundrum, Dublin. **Chickens.**—First, R. W. Boyle, Dundrum, Dublin. Second, W. L. Barclay, Knott's Green, Leyton, London, N.E. Third, T. Statter, Stand Hill, Manchester.

MALAY.—First, Rev. A. G. Brooke, Ruyton XI Towns, Salop. Second, Master C. A. Ballance, 5, Mount Terrace, Taunton, Somerset. **Chickens.**—First, Rev. A. G. Brooke, Ruyton XI Towns, Salop. Second, Miss C. H. Ballance, 5, Mount Terrace, Taunton, Somerset.

CRÈVE-CŒUR.—First, J. Harrison, 14, Central Beach, Blackpool. Second, A. Dixon, Birches Green, Birmingham. **Chickens.**—First, J. Harrison, Blackpool. Second, W. Blinkhorn, jun., Feasie House, St. Helen's, Lancashire.

BLACK HAMBURGH.—First, R. F. Goodwin, Middleton, near Manchester. Second, F. Sabin, Birmingham. Third, W. W. Nicholls, Sale, near Manchester. **Chickens.**—First, S. Shaw, Stainland, Halifax. Second, R. F. Goodwin, Middleton, near Manchester. Third, J. Dixon, North Park, Clayton, Bradford.

HAMBURGH (Golden-pencilled).—First, J. E. Powers, Bigglewade, Beds. Second, C. Tattersall, Waterfoot, near Manchester. Third, S. Shaw, Stainland, Halifax. **Chickens.**—First, F. Pittis, jun., Newport House, Newport, Isle of Wight. Second, Sir St. G. Gore, Bart., Hopton Hall, near Wirksworth, Derbyshire. Third, C. Moore, Poulton-le-Fylde, near Preston.

HAMBURGH (Silver-pencilled).—First, W. Wood, Sheffield. Second, J. Preston, Allerton, near Bradford. Third, H. Beldon, Gilstead, Yorkshire. **Chickens.**—First, D. Harding, Middlewich, Cheshire. Second, S. Shaw, Stainland, Halifax. Third, J. Robinson, Vale House, near Garstang.

HAMBURGH HENS (Pencilled).—First, J. Lowe, Whitmore House, near Birmingham (Golden). Second, J. Robinson, Vale House, near Garstang.

HAMBURGH PULLETS (Pencilled).—First, W. H. Dyson, Snap Farm, Horton Bank Top, near Bradford, Yorkshire (Golden). Second, Sir St. G. Gore, Bart., Hopton Hall, near Wirksworth, Derbyshire.

HAMBURGH (Golden-spangled).—First, I. Davies, Harborne. Second, Sir St. G. Gore, Bart., Derbyshire. Third, J. Robinson. **Chickens.**—First, S. H. Hyde, Taunton Hall, Ashton-under-Lyne. Second, Sir St. G. Gore, Bart. Third, W. Kershaw, Heywood, near Manchester.

HAMBURGH (Silver-spangled).—First, Sir St. G. Gore, Bart. Second, Miss E. Beidon, Gilstead, Bingley, Yorkshire. Third, J. Fielding, Newchurch, near Manchester. *Chickens*.—First, J. Fielding. Second, Mrs. Hurt, Alderwasley, Belper. Third, Miss E. Beldon.

HAMBURGH HENS (Spangled).—First, J. Roe, Hadfield, near Manchester. Second, G. E. Hardman, Rawtenstall, Manchester.

HAMBURGH PULLETS (Spangled).—First, J. Leech, Staffordshire. Second, The Right Hon. the Viscountess Holmedale, Linton Park, Kent.

POLISH FOWL (Black with White Crests).—First and Second, T. P. Edwards, Lyndhurst, Hants. Third, W. Newsome, Bingley, Yorkshire. *Chickens*.—First, Second, and Third, J. Smith, Keighley, Yorkshire.

POLISH FOWLS (Golden).—First, Miss E. Beldon, Gilstead. Second, F. R. Pease, Southend, Darlington. Third, S. Shaw. *Chickens*.—First, W. Newsome, Bingley, Yorkshire. Second and Third, F. R. Pease.

POLISH FOWLS (Silver).—First and Second, G. C. Adkins, The Lightwoods, Birmingham. Third, H. Beldon, Gilstead. *Chickens*.—First, Miss E. Beldon, Gilstead. Second and Third, G. C. Adkins.

ANY OTHER DISTINCT VARIETY.—First, F. H. Neville, Edgbaston (Cuckoo Dorking). Second, E. Pigeon, Lymington, near Exeter (La Flèche). Third, Mrs. D. Haig, Lichfield (Magpie Tarifans).

GAME FOWL (Black-breasted Reds).—First, Sir St. G. Gore, Bart., Wirksworth, Derbyshire. Second, Miss K. Charlton, Bradford. Third, J. H. Williams, Spring Bank, near Welshpool. Fourth, J. Halsall, Ince, near Wigton. *Chickens*.—First, R. Woods, Osberton, Worksop, Notts. Second, J. Halsall. Third, A. B. Dyas, Madley, Shropshire. Fourth, Capt. Wetherall, Loddington, near Kettering.

GAME FOWLS (Brown and other Reds, except Black-breasted).—First and Cup, T. Statter, Manchester. Second, J. Wood, Wigan. Third, G. Hellawell, Walkley, near Sheffield. Fourth, H. Adams, Beverley. *Chickens*.—First, J. Wood. Second and Fourth, E. Aykroyd, Bradford. Third, M. Billing, jun., Erdington, near Birmingham.

GAME HENS (Black-breasted and other Reds).—First, E. Aykroyd, Bradford. Second, J. Wood, Wigan.

GAME PULLETS (Black-breasted and other Reds).—First, Mrs. Hay, Subury, Derby. Second, C. Minors, Sudbury, Derby.

GAME (Duckwings, and other Greys and Blues).—First, Sir St. G. Gore, Bart., Wirksworth, Derbyshire. Second, W. Gamon, The Green, Thorne-le-Moors, Chester. Third, T. Carless, Hovering, near Nottingham. Fourth, E. T. Reynolds, Tysley, Birmingham. *Chickens*.—First, E. Aykroyd, Bradford, Yorkshire. Second, Sir St. G. Gore. Third, J. Holme, Knowsley, Prescot. Fourth, T. Carless.

GAME (Black and Brassy-winged, except Greys).—First, J. Fletcher, Stoneclough, Manchester. Second, Messrs. Bullock and Rapson, Leamington. Third, H. Beldon, Gilstead, Bingley, Yorkshire. *Chickens*.—First, J. Fletcher. Second, H. Beldon. Third, J. D. Newsome, Batley, Leeds.

GAME (White and Piles).—First, Captain C. Curtis, Lutterworth. Second, J. Fletcher, Stoneclough, Manchester. Third, Rev. F. Watson, Messing, Kelvedon. *Chickens*.—First, J. Fletcher. Second, J. Sunderland, Halifax. Third, Rev. G. S. Cruxys, Tiverton, Devon.

GAME HENS (Except Black-breasted and other Reds).—First, Sir St. G. Gore, Bart., Wirksworth, Derbyshire. Second, E. T. Reynolds, Tysley, Birmingham.

GAME PULLETS (Except Black-breasted and other Reds).—First, H. Worrall, West Derby, Liverpool. Second, J. H. Williams, Welshpool.

SINGLE COCKS.

DORKING.—First, E. Tudman, Whitchurch, Salop. Second, J. Robinson, Garstang. Third, Lady S. Des Vœux, Burton-upon-Trent. Fourth, Right Hon. Viscountess Holmedale, Kent. Fifth, Mrs. Arkwright, Etwall Hall, Derby.

SPANISH.—First, H. Lane, Milk Street, Bristol. Second, H. C. Mobbs, Northampton. Third, D. Parsley, Rock Cottage, Bristol.

COCHIN-CHINA (Cinnamon and Buff).—First and Third, Capt. H. Heaton, Lower Broughton, Manchester. Second, Mrs. R. White, Broomhall Park, Sheffield.

COCHIN-CHINA (Except Cinnamon and Buff).—First, J. Poole, Ulverston, Lancashire. Second, R. White, Broomhall Park, Sheffield. Third, C. H. Wakefield, Malvern Wells.

BAHMA POOTRA.—First, E. Pigeon, Lymington, near Exeter. Second, T. Statter, Stand, Manchester. Third, R. W. Boyle, Dundrum, Dublin.

HAMBURG (Golden-pencilled).—First, H. Beldon, Gilstead, Bingley, Yorkshire. Second and Third, Rev. R. Roy, Worcester.

HAMBURG (Silver-pencilled).—First, C. Moore, Poulton-le-Fylde, Preston. Second, J. Holland, Worcester. Third, Sir St. G. Gore, Bart., Hopton Hall, near Wirksworth, Derbyshire.

HAMBURG (Golden-spangled).—First, W. Kershaw, Heywood, near Manchester. Second, Messrs. Bray, Broadhead, & Wilkinson, Choppards, Holmfirth, Yorkshire. Third, Messrs. Burch & Boulter, Sheffield.

HAMBURGH (Silver-spangled).—First, J. Fielding, Newchurch, near Manchester. Second, B. M. Clive, The Highfields, Gravelly Hill, near Birmingham. Third, T. Burns, Leigh, near Manchester.

POLISH.—First, W. Newsome, Bingley. Second, J. Smith, Keighley. Third, H. Beldon, Gilstead.

GAME (White and Piles, Duckwings, and other varieties, except Reds).—First, E. Aykroyd, Bradford. Second, M. Billing, jun., Erdington, near Birmingham. Third, J. Halsall, Wigan. Fourth, J. H. Williams, Welshpool.

GAME (Black-breasted Reds).—First and Second, J. H. Williams, Welshpool. Third, E. C. Gilbert, Penkridge, Staffordshire. Fourth, W. Boyes, Beverley.

GAME (Brown and other Reds, except Black-breasted).—First and Cup, T. Statter, Manchester. First, J. Smith. Second, J. Fletcher. Third, M. Billing, jun., Erdington, near Birmingham. Fourth, G. Clement, Birmingham.

BANTAMS (Gold-laced).—First, M. Leno, jun., Dunstable, Bedfordshire. Second and Third, U. Spray, Dunstable, Bedfordshire.

BANTAMS (Silver-laced).—First, U. Spray, Dunstable, Bedfordshire. Second and Third, M. Leno, jun., Dunstable.

BANTAMS (White, Clean-legged).—First, W. Draycott, Humberstone, near Leicester. Second, Rev. F. Tearle, Leicester. Third, W. Watson, Calstock, Tavistock.

BANTAMS (Black, Clean-legged).—First, T. Davies, Newport, Monmouth. Second, Miss K. Charlton, Bradford. Third, J. Bradwell, Southwell, Nottinghamshire.

BANTAMS (Any other variety except Game).—First, W. J. Cope, Barnsley (Fekin). Second, W. Harvey, Sheffield.

GAME BANTAMS (Black-breasted and other Reds).—Miss E. Crawford, Farnsfield, Southwell. Second, J. W. Kelleway, Merston, Isle of Wight. Third, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth, Derbyshire. Fourth, Hon. W. T. W. Fitzwilliam, Wentworth Wood House, Rotherham.

GAME BANTAMS (Any other variety).—First, R. B. Postans, Brentwood, Essex. Second, R. Hawksley, jun., Southwell, Nottinghamshire. Third, J. W. Kelleway, Merston, Isle of Wight.

GAME BANTAM COCKS.—First, J. W. Kelleway, Merston, Isle of Wight. Second, C. Auksland, Heetwell Cottage, Chesterfield. Third, R. B. Postans, Brentwood, Essex.

DUCKS (White Aylesbury).—First and Third, Mrs. Seamons, Hartw 1 Aylesbury, Buckinghamshire. Second, J. K. Fowler, Prebendal Farm Aylesbury.

DUCKS (Rouen).—First, S. Shaw, Stainland, Halifax. Second, H. Worrall, West Derby, Liverpool. Third, J. Anderson, Meigle, N.B. Fourth, Capt. W. Hornby, Prescot.

DUCKS (Black East Indian).—First, J. W. Kelleway, Merston, Isle of Wight. Second, Mrs. Hayne, Fordington, Dorchester.

DUCKS (Any other variety).—First, S. Shaw, Stainland. Second, R. P. Williams, Glasslawn, Dublin.

GESE (White).—First, W. K. Duxbury, Leeds. Second, W. Kershaw, Heywood. Third, J. Faulkner, Burton-upon-Trent.

GESE (White).—First, Mrs. Seamons, Hartwell, Aylesbury, Bucks. Second, J. Lyett, Marston Villa, Stanford.

GESE (Grey and Mottled).—First, W. H. Denison, Woburn, Beds (Toulouse). Second, J. Lyett, Stanford. Third, Her Grace the Duchess of Marlborough, Blenheim Palace, Woodstock, Oxford.

GESE (Grey and Mottled).—First, Mrs. Seamons, Hartwell, Aylesbury, Bucks. Second, W. Lort, jun., King's Norton, near Birmingham (Old English).

TURKEYS.—First, J. Smith, Breeder Hills, near Grantham (Cambridge). Second, Rev. H. G. Baily, Swindon (Cambridge). Third, G. R. Dartnell, Arden House, Henley-in-Arden (Norfolk). *Poults*.—First, Mr. C. Browne, Withington, Shrewsbury (Cambridge). Second, J. Beasley, Brampton, Northampton (Cambridge). Third, J. Smith (Cambridge).

PIGEONS.

TUMBLERS (Almond).—First, F. Else, Westbourne Grove, Bayswater, London. Second, F. Esquillant, Oxford Street, London. Third, P. Eden, Cross Lane, Salford, Manchester.

CARRIER (Black).—*Cock*.—First, F. Else. Second, P. Eden. *Hens*.—First, F. Else. Second, P. Eden.

CARRIER (Any other colour).—*Cock*.—First, P. Eden, Salford. Second, Messrs. W. Siddons & Sons, Aston. *Hen*.—First, Messrs. W. Siddons and Sons. Second, F. Else, Bay-water.

POTTER (Red or Blue).—*Cock*.—First, G. R. Potts, Sunderland. Second, P. Eden, Salford. *Hen*.—First, G. R. Potts. Second, P. Eden.

POTTER (Any other colour).—*Cock*.—First, P. Eden, Salford. Second, F. Else, Bayswater. *Hen*.—First, G. R. Potts, Sunderland. Second, P. Eden, Salford.

BALDS.—First, T. Ridpath, Rusholme, Manchester. Second, F. Esquillant.

BEADRS.—First, W. H. C. Oates, Besthorpe, Newark. Second, F. Else.

TUMBLERS (Mottled).—First and Second, P. Eden, Salford.

TUMBLERS (Any other colour).—First, J. Fielding, jun., Rochdale. Second, J. Ford, London.

RUNTS.—First, T. D. Green, Saffron Walden, Essex. Second, C. Bulpin, Bridgewater.

JACOBINS (Yellow).—First and Second, J. T. Lawrence, Bredfield, Everton, Liverpool.

JACOBINS (Any other Colour).—First, J. T. Lawrence, Liverpool. Second, T. Ridpath, Poplar House, Rusholme, Manchester.

FANTAILS (White).—First, C. F. Allison, Friar's Place, Acton, Middlesex. Second, T. Ridpath, Poplar House, Rusholme, Manchester.

FANTAILS (Any other colour).—First, F. H. Paget, Birstall, Leicester-shire. Second, J. W. Edge, Aston New Town, Birmingham.

TRUMPETERS (Mottled).—First, S. Shaw, Stainland, Halifax. Second, W. H. C. Oates, Besthorpe, Newark.

BRAHMA POOTRAS.

NOTWITHSTANDING your recent fiat that a Brahma is only a Cochin in masquerade, I am not discouraged and without assuming to be either Attorney or Attorney-General for Brahma Pootra Land, or any other land, from supporting the opinion of your correspondent "B," that the breeds are distinct. Their breeding true to colour is not a decisive

proof I admit, but that is not the point. Their not breeding true to colour would have been direct evidence against them. Stability in this respect negatives an adverse testimony.

As to the American story, I confess that I lay little stress, if any, upon it, or any other Yankee story, if against usual experience. It is not remarkable for clearness in itself. I do not intend to take up the question of origin of species. That I leave to Heaven and Mr. Darwin. But if Brahmases were really in the beginning a cross between a Cochin and a Chittagong, then a Chittagong and a Cochin have originated a breed and that is all. I never saw a Chittagong, but it is said by the books to be a cross between Malay and Dorking. In that case, a cross again with a Cochin, retaining permanently its peculiar type, would be an anomaly indeed. However, let me suggest an *experimentum crucis*. Let some enterprising spirit cross a Malay and a Dorking and obtain a Chittagong. Cross this Chittagong with a Cochin, and if the produce has all the characteristics of a Brahma, *cadet quæstio*. There is an end of the matter.

But, sir, if constancy in the peculiar habits, disposition, and properties of a bird are no evidence of breed, I am at a loss to know what is. Varieties of Cochins differ in colour, but in these respects they are all alike. So with Dorkings. So with Hamburgs and other varieties of the same breed. And in these respects there is as wide a difference between a Cochin and a Brahma, as between any two distinct breeds whatever. Their mode of laying is quite different. The Cochin lays a few eggs and then sits. She leaves her young often prematurely to lay and sit again. The Brahma lays a great many eggs—a hundred or more—before she sits, and usually sits but once and rears her brood carefully. The eggs are rather different in shape. They are a little rougher in the shell so as to be discerned by the feel, such, at least, is my experience. Their chickens are easier to rear. They put on flesh more readily. They, perhaps, range something wider. The crow of the cock is very different, nearer the note of chanticleer than that dying bray of the donkey, which is by no means suggestive of nightingales. It may, perhaps, be alleged that he gets this note from the Dorking quartering in the Chittagong side of his shield. He is by no means so cowardly a bird, and will stand boldly up to a Game cock and punish him, as I know to my cost. If all these peculiar characteristics with an aspect and colour constant and sufficiently distinct are marks only of a Cochin merely varying in feather, it is certainly the most remarkable variety known to the poultry world.

In point of fact, it is these very characteristics that stamp their value on any breed. It is for their peculiar excellence in these qualities, not for their feathers, that different breeds are approved and carefully kept pure. If it was not for their pre-eminence as layers, neither comb, nor hackle, nor spangle, nor pencil, could keep the Hamburgs from oblivion. To disregard such important distinctions seems impossible. It is not because it is a variety of Cochin that the Brahma is kept up and highly prized, but because it possesses peculiar and valuable properties of its own to which the Cochin has no pretensions whatever.—IMPLUMIS.

[Admitting all the merits that our animated correspondent claims for Brahma Pootras, yet those merits are no more than characterise a variety. The same may be said of the Coloured Dorking as compared to the White Dorking and others. All the essential characteristics of form and plumage are the same in the Cochin-China and the Brahma Pootra. We have no expectation that the cross-breeding suggested would do more than demonstrate that the Brahma is a variety of the Cochin-China, but we fear that even that would not alter the opinion of our correspondent. He ignores direct evidence as a mere Yankee story, and it has been recorded as a result of experience, that

"A man convinced against his will
Is of the same opinion still."]

have merely to refer you to the advertising columns of your own Journal of the same date (8th inst.), to show the inconsistency of this, I believe inadvertent, statement. There has been a slight change this year in the management, but that is no reason why such a statement should have crept into your report.

As the originator of the Glasgow Show and present Secretary, I certainly feel happy to think that it should have been considered a model Show, and I trust that it will always continue such. I enclose you a prize list which is more intended to produce honourable competition than pecuniary gain.—JAMES RUTHVEN, *Secretary*.

[The gentleman who sent us a report of the Sunderland Show we are quite sure only repeated what he was told, and he will rejoice, as we do, that he was misinformed.

The Glasgow Show is to be held on the 23rd and 24th of December. The prizes are liberal in money, in addition to medals and other rewards; and as every variety and sub-variety has a separate class, the Show especially deserves the support of Pigeon and Canary fanciers.]

THE ORIGIN OF BRAHMAS.

MANY years ago, when Brahmases were not the "household birds" they have now become, I seized my pen and, like many others, rushed into print in defence of my pets. I well recollect there was a long wordy war, but it reminded me somewhat of the tale told of a gentleman rather noted for his longwinded descriptions always given in a somewhat legal manner. This person on one occasion, meeting a friend evidently in a great hurry, nevertheless secured him as a listener, commenced his minute description, and after detaining his impatient friend on tenter hooks for a considerable time, he wound up with this appeal—"Now, do not you think that perfectly conclusive?" "Oh, not the shadow of a doubt about it," said his impatient friend, glad of the respite; "I wish you good morning." "Hold," says the other, "wait one minute; there is as much to be said on the other side of the question." His friend, however, bolted, saying he was perfectly convinced.

Brahma origin is like this, there is a vast deal to be said for and against according to our bias; but, perhaps, it only wastes the time of impatient friends, so I say honestly at once, although I have headed this communication as I have done, that I do not intend at present to enter into the discussion, I plead guilty to having felt awfully pugnacious on this topic once or twice lately—first with Mr. B. P. Brent, when I vented my spleen on paper for "our Journal," but saved the readers the infliction. Quite recently, dear Messrs. Editors, with yourselves, when you gave my pets that quiet dig in the ribs, and gave it as your opinion that the bar sinister belonged to them. If I had not a wondrous kindly feeling for "our Editors" as well as "our Journal" I might have called you out, and, being but a small man myself, would not have objected to my size being chalked out on your body—"all shots outside the line not to count!"

The question of altering names has been mooted on several occasions of late, and you gave us a pretty list lately for our pets, but I am content with "Brahma." It is as euphonious as Dorking or any other name, so it appears to me, and, therefore, I shall not adopt "Bahama Padua," or any other of the crackjaw names, even although "a rose by any other name might smell as sweet." Still, in these notes, I was much tickled with one thing, and I must say that, according to those notes, we Brahma breeders are remarkably clever fellows. You said the first ever shown had "unmistakeable topknots," I quote from memory. Well, where are these topknots gone? Why do not Game-fanciers come to us for the secret? then there would be no occasion to trim their birds! What wonderful deplumatory have we used, and why is it not advertised?

Joking apart, dear Messrs. Editors, although, on second thoughts, I shall not call you out, as even a hit outside the chalk line might injure "our Journal," I nevertheless shall send you a challenge. It is this—state what you consider the marks of a pure breed, then, perhaps, some of us may have a word or two more to say in defence; and come what may, if you prove us the most wretched mongrels that ever existed, I shall reply, "Handsome is that handsome does,"

GLASGOW PIGEON AND CANARY SHOW.

HAVING been from home I did not receive my usual copy of your Journal until to-day, and on looking over the report of the Sunderland Show I was somewhat surprised to find stated therein that the "Glasgow Show was given up." I

I might have said "looks;" but I will write no more than
—Y. B. A. Z.

Since writing the above, "our Journal" with "B.'s" letter has reached me. I will only add, taking your words, that I want the "essentials on which a distinct breed can be founded." I should also like to know the breeds you do consider pure, we shall then have some foundation for the discussion.—Y. B. A. Z.

RAILWAY CHARGES FOR POULTRY CARRIAGE.

I NOTICE with much satisfaction that some one has ventilated the question of the high rates charged for carriage of poultry by railway companies in general, and the London and North-Western in particular.

Having large dealings with the latter company, I tried the effect of individual influence and representation, but in vain. On many others besides myself, who live at a great distance from all shows, this high carriage question becomes a grinding oppression, and reduces in many cases our contributions to shows to a very small minimum. If a united appeal were to be made by a united body of exhibitors, such as meet at Birmingham, I am sure the directors would at once mitigate the evil complained of, which is so much at variance with the spirit of the age, and which while it checks progress, must curtail those profits which from poultry shows and exhibitors ought to be something considerable.

While carrying unsold stock back free, on what principle is an extra rate levied on poultry? What has the feathered world done to merit so unenviable a distinction?—VICTIM.

THE SWARMING SYSTEM.

FROM my own observations this year and last, I am satisfied that hives which are permitted to swarm, if forward, will yield a larger harvest of honey than they would do if kept upon the conservative principle. I made a swarm on the 18th of May by taking a frame out of a bar-and-frame hive with the queen, and then placing it in an empty hive which was then located upon the stand of the old hive. I weighed this swarm a few days ago, and found it weighed about 40 lbs. nett. At the end of July it would have been at least 7 or 8 lbs. more, as my bees have done nothing since that time. A second swarm was made from the same stock, yet the old hive was equal in weight to the first swarm. Three storified hives yielded on an average 35 lbs. each of pure honey in their supers; but the stock hives were in each case very light, and required copious feeding to make them safe for the winter. Other hives which swarmed were very heavy.—J. E. B.

BEES CAREFULLY FEASTED.

WE are told by the wise man that "There is nothing new under the sun;" and although sorry to brush off the bloom of novelty from "RUBY BLUSH'S" proposition of making our poorer hives sharers in our Christmas festivities, I may relate a circumstance of a somewhat similar kind which I am assured actually took place.

Among the superstitions yet current in some parts of this county is one which would certainly commend itself to the sympathies of Jonas Jackson if he ever heard of it; and if he has not, I hope he will forthwith add it to the list of customs which he has already promulgated, and the religious observance of which he proclaims to be essentially necessary to all who would attain eminence in the occult mystery of successful bee-keeping.* Not only is it requisite, as he says, whenever any joyous event takes place, such as a marriage or a christening, to make the bees partakers of the good cheer provided for the occasion, but it is absolutely essential that no one item of either the dainties or the substantial should be omitted.

The evening of the day which had witnessed the departure of a newly married couple having arrived, the "gude man" proceeded to question his spouse as to the due fulfilment of the indispensable ceremony of presenting the bees with a

* Vide JOURNAL OF HORTICULTURE, VOL V., page 99.

modicum of every eatable and drinkable that had been provided for the wedding feast. "Had they had a bit of the turkey, the chicken, the ham, the boiled beef, and, though last not least, the wedding cake?" "Yes." "Some of the spirits [rum, I hope, not being omitted], ale [Scotch, of course], and cider?" "Yes." "Baccy?" "No, what could they do with baccy? bees can't smoke," urged the wife. "Nonsense, Betty," replied her lord and master; "if they can't smoke they can chaw!" And so the omission was supplied in good time, "baccy" being forthwith added to the previously incomplete list of dainties; and having been, we may presume, in due course "catawamptiously chawed up," as the Yankees have it, the care and anxiety of the worthy couple were doubtless rewarded by the continued and unfailing prosperity of their well-cared-for apiary.—A DEVONSHIRE BEE-KEEPER.

COWS MILKING THEMSELVES.—I know for a certainty that cows sometimes do suck themselves. The proper remedy—the one used in the Vale of Black Moor, in the county of Dorset—is a headstall with spikes in the nose-band.—W. F. RADCLIFFE, Rushton.

OUR LETTER BOX.

EDITORIAL RESPONSIBILITY (H.).—Your informant, and the correspondent in a contemporary, are totally wrong. No one, except the two gentlemen whose names appear upon our first page, has any control over the editing of this journal. They are responsible for all its contents, and nothing appears in its columns without their assent.

GIDDY GOOSE (G. A.).—A small blood vessel has burst upon the brain. Quiet and the avoidance of hard corn are your only available helps.

WHITE COCHIN-CHINA FOWLS (*A Very Old Subscriber*).—We do not know the address, and certainly would have no dealings with the person you name. Write to some of the prize-takers, or, what is better, go to some poultry exhibition, and buy pullets from one exhibitor and a cockerel from another.

HENS EATING THE EGGS THEY ARE SITTING ON (J. W.).—Hens with such a habit as you mention should be marked for the kitchen, and killed as soon as they have done laying. To allow such to sit is to jeopardise valuable broods at this season of the year. The driver of a Hansom cab in which we were riding a short time since, assured us, when the horse had kicked away all the front except the iron framework, that "There never was a quieter oss after the first few minutes." In fact he was fresh. We should like in future to have him well worked before we rode behind him. It may be your hen, like the cab horse, is only vicious "at first." Therefore, if you wish to retain her services, put her for some days on some good hard artificial eggs. She will peck them till she is tired, and will then give up the job in disgust. We can hardly give an opinion about the hen of Dorkings at Islington. Mistakes are unavoidable sometimes, and this may have been one.

BANTAMS WITH COCHIN-CHINAS (*Freeland*).—We say yes. We have done it for years with perfect safety.

POULTRY EATING WALNUT HUSKS (J. M.).—We have never known the green husks of walnuts to injure poultry. We have two pens entirely shadowed with walnut trees, and after they are threshed the ground is covered with husks. We have never seen fowls pick them up. We shall feel glad to have the opinions of competent persons as to the properties of these husks. Our correspondent had a Dorking cockerel die after thirty-six hours illness. His crop was full of walnut husks.

WHITE FLUFF AT BASE OF BLACK RED GAME COCK'S TAIL (*A Doubter*).—Yes! it is always there. The amount is uncertain, and varies much. It is not a desirable thing in an exhibition bird, nor indeed in any other. If two birds of equal merit and value were offered to us, but one had this peculiarity more developed than the other, we should reject him on that account.

TRAINING HIGH-FLYING TUMBLER PIGEONS (W. C. T.).—Your best and easiest way is to obtain a few pairs of already-trained highflyers, which will save you much trouble. If, however, you have already a breed of good pedigree which you wish to train, you must take the trouble to see that they are well looked after, fed on good food, as peas, tares, lentils, or Indian corn; that all that can fly well are turned out once a-day, in the morning is best, and put on the wing. At first you must make them fly, if it is only for five minutes. The time can be gradually increased, until they will fly without trouble for from two to four hours. As soon as they settle they should be coaxed in, and kept confined for the rest of the day; nor must they be allowed to fly about with other Pigeons. As they become accustomed to daily exercise they will not have much desire to feed until they have flown. To prevent their going out quite empty it is as well to give them a small feed of hemp or canary seed; but they must not be full fed, for they cannot fly well with a heavy crop full, but after a long fly they will eat ravenously. Care must be taken to associate being out with flying. Lazy birds, sick ones, or such as have a bad habit of settling on some chimney or high building, must not be let out, or had better be got rid of.—B. P. BRENT.

LOVING BIRDS DYING (*A Lady Subscriber*).—It is impossible to say what was the cause of your birds dying. The general treatment is to keep them warm and feed them on canary seed; also give them, in a separate feeding box, some millet, and occasionally a few oats (soaked all night in cold water), and the tops of watercress sparingly. Groundsel is only good for them in the spring of the year, and the early part of the summer, and then but very sparingly. We presume that you have given them water, which is necessary.

WEEKLY CALENDAR.

Day of M'nth	Day of Week.	DECEMBER 6-12, 1864.	Average Temperature near London.	Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.	
6	Tu	Annual Meadow Grass flowers.	47.7	36.1	41.4	19	53 af 7	50 af 3	15	0 morn.	8 32	341

10	S	Polyanthus flowers.	46.7	33.3	40.0	24	58 7	49 3	11	2 19 4	6 45	345
11	SUN	3 SUNDAY IN ADVENT.	45.5	32.4	39.0	16	59 7	49 3	51	2 33 5	6 18	346
12	M	Wallflower in bloom.	45.6	33.7	39.6	16	0 8	49 3	39	3 40 6	5 50	347

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 48.3°, and its night temperature 34.5°. The greatest heat was 63° on the 12th, 1841; and the lowest cold, 16°, on the 9th, 1851. The greatest fall of rain was 1.02 inch.

ORNAMENTAL TREES AND SHRUBS.

LTHOUGH many valuable introductions of ornamental trees and shrubs have been made during the past twenty years, our parks and pleasure grounds remain in much the same condition as regards the general features produced by ornamental trees as before the introduction of those novelties. Whether we examine public or private parks and pleasure grounds, the sameness of the materials employed renders the landscape monotonous, and leaves nothing for the eye to fix on. Taking the majority of our parks from the enclosure of ten up to that of a thousand acres in extent, in them we find nothing of interest in the way of trees, except those peculiar to the soil, and which may have sprung up from self-sown seeds, or been part of the original forest, so far as there is any indication of their being there for the purpose of embellishment. There are thousands upon thousands of acres of parks of various sizes, the trees of which are in an ornamental point of view utterly valueless, remaining year after year without answering any purpose, producing an inharmonious, uninteresting landscape of a monotonous aspect, most wretched as a picture, and commonplace as to the trees employed. In many places the whole of the sylvan shade and glade is furnished by very few species; some cannot boast of more than a dozen, others of not more than two or three, and most of these species are indigenous to the locality.

This state of things may at first thought appear desirable, for it is desirable where many acres of land are occupied with trees, that they should pay. In a commercial point of view, such trees as those above referred to, are no less deceptive than when considered as ornaments, for they, like hedgerow timber, are unremunerative, and so are all trees standing singly, or wide apart in groups. I found that in a wood of large dimensions fifty Oak trees, calculated to be between two and three hundred years old, occupied less ground with the spread of the branches than ten of the same age planted singly in a park, and though the latter were much larger in circumference of stem, they had such short stems that each did not contain one-half the amount of the measurable timber of those in the wood. If this be a fair example of the paying qualities of park timber, the question of profit is at once disposed of, and the ornamental value of the trees being equally small, we are left in the dark as to what prompts their toleration. It is undoubtedly wise to plant, or retain if planted, a number of trees of the kinds common or indigenous to the locality, in order to afford shelter to the more tender, and to show the character of the district; but to retain an undue proportion of such to the exclusion of species which are

more desirable, because calculated to do away with the monotony, and equally valuable as timber, would lead to the conclusion that they are kept at a dead loss to the owner through the deterioration of the timber from natural decay. Irrespective of their not paying, they are ineffective from being badly placed and resembling a jungle. It may seem undesirable to plant to produce that sublimity which some see in rotten trees, and I can only say, an object naturally beautiful is doubly so when it is also useful.

Viewing the subject with a like eye in relation to our gardens, the same remarks hold good, though there is the difference that no one expects trees and shrubs in gardens to pay, but to yield an amount of gratification corresponding to the sum expended. There is a great deal of sameness in the trees and shrubs employed, and a great consequent loss of pleasure, and the interest is all but annihilated. This is a most deplorable state of things.

The choice of forest trees for the embellishment of gardens is another prevalent error, as for size they bear no proportion to the situations in which they are placed. Suiting the size of trees to the extent of the grounds in which they are to be placed, though of great importance is very generally disregarded. Trees of some kind are indispensable in all gardens, for whilst they give beauty, they also afford an agreeable shade during the hot days of summer; but planted, as they often are, in small gardens, they must either be curtailed by frequent cuttings or mutilations, or be left to usurp the whole of the contracted space to the exclusion of species better suited, as regards size, to the extent of the ground. These large trees in a few years, supposing them to have been planted small, attain such a size as to smother everything else, rendering it altogether impossible to have variety, for very few shrubs or plants will grow under them, and to have either green turf or healthy flowers, the two grand objects for which gardens are desired, is impossible.

Then, taste in the distribution of the trees and shrubs in gardens is very much sinned against. It is common to find evergreen and deciduous trees and shrubs planted on lawns singly, or in groups, with flower-beds between them. The single trees bear no relation to the groups, and the beds are not connected with them, and the consequence is, they do not combine so as to form either a regular or symmetrical whole. It certainly is highly pleasing and picturesque to see trees, shrubs, and flowers all struggling together for the mastery in a natural state; but this sort of beauty is unsuitable for garden scenery. The object of collecting trees, shrubs, and flowers in gardens, is to produce them in a higher degree of perfection, and to show them off to greater advantage than can be done in a state of nature. Whatever in the planting, cultivation, or management of a garden interferes with these two objects, the perfection of the plant, and its display to the greatest advantage, is wrong.

Now, the indiscriminate mixture or distribution of ligneous and herbaceous plants on a lawn, leads to no good result, but the effect of one injures the other. They cannot form a picture. The expression of a tree is one of grandeur and dignity, and to be impressed with this the eye must be at a certain distance from the object, so as to comprehend the trunk, branches, and head, as a whole. As to a shrub or a clump of such, it cannot be denied that its beauty is of a very different kind from that of an herbaceous plant. On the other hand, the expression of an herbaceous plant in flower is that of brilliancy of colour, and beauty of detail, and to enjoy these, the eye must be quite near, so that it may be directed to the flower and its different parts.

The beauty of any object or scene consists in the unity of expression—that is, in the tendency of all the parts of that object or scene to unite in conveying to the mind a pleasing impression. But, with the mixture of trees, shrubs, and flowers, they each detract from, instead of uniting to form a whole. To enjoy the flowers the eye must look down, and be exclusively directed to them; and to enjoy the trees the flowers must be overlooked. A picture, a scene, or an object, to be appreciated as a whole, and to produce its full impression on the mind, must be capable of being seen with the eye in one fixed position. There are two distinct kinds of scenery—1st, forest-like; and, 2nd, garden-like scenery; and these distinctions are founded on the principle that the mind can only attend to one thing, and one kind of thing at one time.

To apply this it follows that when flowers are the principal objects, the trees and shrubs must be kept subordinate, and when the trees and shrubs are the chief objects, the flowers ought to be kept subordinate. In a garden there is no way of doing this but by keeping them apart, so that the one may form the foreground or principal object nearest the eye, and the other be in the distance or farthest from the eye.

The effect of dug ground near a tree is to diminish dignity of expression, and shrubs, except when small, having more or less the expression of trees, though less discordant, are so much so as to cause their exclusion from symmetrical flower gardens. In these the greatest effect is produced when the flower-beds are not mixed with shrubs, because these prevent the eye of the spectator discerning the symmetry of the figure, of which the beds form the component parts.

Where, however, the object is not symmetry, but irregularity, variety, and intricacy, then the beds of flowers and groups of shrubs, or single specimens, may be intermixed, and this sort of disposition produces the greatest beauty of which an irregular flower garden is susceptible, providing always that each group is planted with one species, or with similar species of one genus, all attaining their greatest beauty at one time; and whether flowers or foliage be their chief attraction, they should unite in forming a whole. Every bed of flowers, and group of shrubs or trees, will, therefore, if placed separately, form, of itself, a whole, and bear no relation to forming a whole or picture to be viewed by the eye from one fixed point. It very often occurs in irregularly-formed gardens that there are many straight lines which are indicative of regularity, whilst the main feature is irregularity, and this is inconsistent with a plan which, in all its great features, is irregular.

I shall not pursue the subject of the many different styles of arranging gardens further than to give the principles of them, which cannot be set aside to gratify individual taste.

The different modes of creating artificial landscapes may be distinguished and defined as four—1st, the geometrical; 2nd, the picturesque; 3rd, the gardenesque; and 4th, the natural or rural style. The geometrical style consists in laying-out and planting grounds in geometrical figures—that is, in mathematical forms or lines—regularly straight, or regularly curved. French and Dutch gardens are in this style, the majority of our own at present being simply modifications of the French and Dutch styles, especially as regards displaying masses of flowering plants in geometrical figures. For a limited space, and where a variety of trees and shrubs will not grow (as in or near our large manufacturing towns), or are not desired, no description of garden is better adapted to please the general taste than one laid out geometrically.

The picturesque style is exemplified by the trees and shrubs being planted at irregular distances, as they are in natural forests and groups, so as exhibit such a general union as would look well in a picture. In planting the trees and shrubs intended for pictorial effect, they should be scattered over the ground in the most irregular manner, both in their disposition with reference to their immediate effect as plants, and with reference to their future effect as trees and shrubs. In planting, thinning, and pruning, for picturesque effect, the beauty of individual trees and shrubs is of little, if any, consequence: because no tree or shrub in a picturesque scene should stand isolated, each being only considered as forming part of a group or mass. In planting a picturesque plantation trees should prevail in some places, in others shrubs, in some parts they should be thick, in others thin; two or three, at least a tree and a shrub, ought always to be planted together. The beauty of the isolated tree cannot be, for the beauty of a tree or shrub in the picturesque style consists in its fitness to group with other objects. A tree or shrub obtains its fitness to group with other objects not in the perfection of its form, but in that imperfection which requires another to render it complete. This style is admirably adapted for park and pleasure-ground scenery; some of the best specimens are visible at Studley, near Ripon, and at Redleaf, Kent.

The gardenesque style is characterised by the trees and shrubs being planted at irregular distances, whether in masses or groups, and so as never to crowd each other, preserving the individual form of a tree or shrub at a near view, but at a distance forming masses and groups such as might be painted, though not selected in preference to a picturesque scene by the artist. In planting, thinning, and pruning, in order to produce a gardenesque effect, each individual tree or shrub should stand at such distances from others that its beauty as a single specimen may be seen, though the whole should group when viewed at a distance. Every tree, shrub, or herbaceous plant, in the gardenesque style of laying out, derives its beauty from the perfect manner in which it is grown; and gardens arranged in this style may be considered the most beautiful of all, because the gardenesque addresses itself to the lovers of landscape scenery, the botanist, and the gardener, for it enables them to enjoy the beauty of the whole as a garden scene, and look at the trees, shrubs, and plants individually when near. Combining these two advantages, the gardenesque style stands highest in the scale of art, not the least of its merits being the instruction and pleasure derived from viewing plants grown to the highest state of perfection.

The natural, or rural style, consists in producing artificially that which appears natural when contrasted with the artificial scenery by which it is, or may be surrounded. Natural scenery, imitated according to art, is the legitimate province of landscape gardening, and includes two modes—the picturesque and the gardenesque, or nature subjected to a certain degree of cultivation. To design and execute a scene in the picturesque style would require the eye of a landscape painter, whilst the gardenesque would not only require the eye of a landscape painter, but the science of a botanist and architect, and the knowledge of a horticulturist. Every part of nature may be imitated according to art, whether it be rude or refined; but nothing that has art applied to it can ever be mistaken for a work of nature, and if imitations they ought to be avowed as such.

There is, in addition to the four styles of landscape gardening already noted, another known as fac-simile imitations of natural scenery; but they cannot be considered as belonging to gardening as an art of culture, because all appearance of culture is to be avoided, and they cannot be considered as belonging to gardening as an art because it is intended that the result shall not be recognised as the work of art, but mistaken for a work of nature itself. They are simply impositions. They do not come within the province of a gardener. Any person with a painter's eye, and the assistance of labourers, &c., will form them as well as a landscape gardener, if not better.

These are the principles which regulate the operations of the landscape gardener, as I have learned them from our best authorities, and in applying them to the distribution of trees and shrubs to be named hereafter, I hope to show that these principles are too often disregarded. At the same

time I shall endeavour to revive a taste for the more extensive planting of ornamental trees and shrubs in our parks and pleasure-grounds, as well as to convey some hints that may be useful to those making alterations on their estates.

G. ABBEY.

(To be continued.)

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 5.

DURING my absence from home I had a fernery made for my spoil. I chose an open space of ground facing due south, so that in the summer time the Ferns would have the full light and warmth of the sun's rays. I did this, because I had noticed that the most rare and delicate Ferns I had seen chose for themselves situations of the like character. The back of the fernery abruptly descended to the edge of a pond, through which there was a running stream. On one side there was an Elm tree, which overshadowed a small part of the fernery. In making the rockery I had but one idea, and that was to provide a suitable home for the Ferns—one in which they could revel, and enjoy life as everything was created to enjoy it. The beauty of the rockery was but a secondary consideration, and, besides, at the best of times rockeries are but shams, and I never yet found a Fern that was taken in by them. If you transplant *Septentrionale* or a *Cystopteris* from a rock, so bare that the wonder is how it found sufficient food to sustain life, to similar conditions, it will die. All Ferns in cultivation require depth of soil and good drainage; so I had a large pit dug and filled with drainage, then I put in good rich earth and leaf mould. The stones or rock were disposed so as to form compact little beds about a foot square, rising tier above tier, the highest within convenient reach. When completed, the fernery looked like the terrace gardens one sees abroad, and it had a beauty peculiarly its own—a sort of tidy fitness for the purpose it was designed for.

My fernery was like my book of dried Ferns: for a year or two it presented instances of my failures rather than of my success. I planted large Ferns at the top—*Filix-mas cristata*, *Filix-femina* with black stalk, *Onoclea sensibilis*, *Lastreas*, and *Oreopteris*. As time went on I found this plan would not succeed; the drip from the large Ferns saturated the next tier of plants, and wherever the drip fell the fronds became decayed and mouldy. This I have found to be invariably the case. I also found the plants on the side of the fernery under the shadow of the Elm tree gradually grow unhealthy-looking and dwindle away. A *Polypodium cambricum*, which is now a mass of healthy fronds and brown creeping roots, for two years obstinately refused to give me more than two little stunted fronds; but directly I moved it to an open sunny space it seemed to smile in my face, and very soon new and fine fronds were sent up to thank me.

Onoclea sensibilis is a native of Virginia, but it is so hardy and free in its growth that no fernery should be without it. The fronds are large and strongly ribbed, something like the leaves of the Rhubarb: it sends up long bare spikes crowned with fruit, as in *Osmunda regalis*. *Onoclea sensibilis* is a very Bedouin in its wandering habits. It seldom pitches its tent for two seasons following in the same place. Give it plenty of house room this year, make it never so comfortable, and next year it will pass up far away in the midst of a bed of *Dryopteris* or *Cystopteris*. It makes itself at home anywhere, runs up hill or down hill with equal facility, and is never found where it is expected. I soon found the limits of the quiet fernery too circumscribed for the versatile habits of *Onoclea*; so I moved it to a larger sphere, where it wins general approbation, and brings up a numerous family creditably.

The common hedges of Warwickshire furnished me with *Polypodium vulgare*, which I planted in the rough crevices of the sides and back of the fernery. It grows well without care wherever there is thorough drainage. It prefers living amongst the *dbris* of decayed wood; and the rich golden fructification against the bright green of the fronds makes it "a thing of beauty," and consequently "a joy for ever," in any situation.

From the lanes about Fillonghley I brought *Asplenium*

trichomanes for the lower terrace. I also found *Adiantum-nigrum* near Fillonghley. This I planted in the crevices between the blocks of rock in several places, its wavy habit making it very useful for the adornment of the rough stone. The old bridge at Stoneleigh—about which so many a tale and legend exists—furnished *Ruta-muraria* for my many vain attempts at cultivation.

In the neighbourhood of Corley Moor I found *Lastreas oreopteris*, *dilatata*, and I believe *L. spinulosa*, also the *Filix-femina* with the black stalk.

The beautiful lake at Arbury contributed some *Osmundas*, but they were not born on the soil, so I only placed them by the pondsides, looking forward to the time when I should find them growing in a habitation of their own choice. *Blechnum spicant*, with its curious spikes of fertile fronds, is also common in Warwickshire. It abounds in the hedges and lanes of Exhall, Fillonghley, and many other places, and forms handsome tufts for the lower ranges of a fernery, or for spare corners where wavy green is wanted. I have found it with the ends of the fronds divided, as in the Hart's Tongue; but the divisions were never more than two, or at the most three, and the duration of the peculiar feature is very uncertain. I have lately bought of Mr. Ivery, at Dorking, a very beautiful variety of the *Blechnum* called *ramosum*. The end of the frond is tufted. I imagine this tuft to have been either made or increased by cultivation, as I have never found a Fern in the wild state approaching to it nearer than the cleft end I have mentioned. I sent to Mr. Ivery at the same time for a *Polystichum lonchitis*, but I received a plant which appears to be a mild form of *lonchitidioides*. The pinnules do not lap over each other; the habit of the Fern is reclinate and flabby instead of firm and erect. It is a young plant, but I fancy I have named it rightly.

The *Scolopendrium vulgare* grows plentifully in Warwickshire, but I have seldom met with any of its many varieties there. About Fillonghley it may be found with its long waving fronds measuring nearly three-quarters of a yard. When the snow hangs in rich wreaths about the hedges in the dear woodlands, and all nature seems dead and shrivelled around, hidden beneath its snow-white veil—under the friendly shelter of the hedge they have made their home, the *Scolopendriums* hold high revel in their brightest suit of green, laughing at winter's icy touch, knowing it has no power to reach the warm sap that flows beneath their thick coats.

The woodlands of Warwickshire have a charm that belongs only to themselves, and one that lingers about them through every season of the year. Life there seems to take a richer, fuller tone than elsewhere. The trees strike their roots deep down in the soil, and send up their huge limbs heavenwards, forming shadows still and deep in the summer time. The thickets are musical above with the song of birds, and beneath lies spread a fairylike carpet of a million wild flowers. There the lark sings her sweetest song, soaring heavenwards, and the nightingales fill the evening air with melody; and man, living amidst scenes like this, insensibly shapes his life and inner thoughts into unison with the scenes around him, and, as Warwickshire Will has it—

"Finds tongues in trees, books in the running brooks,
Sermons in stones, and good in everything."

The converse he holds with them is earnest and true; and whether the biting autumn wind makes him steel his body to endure, or the summer air woos him to gentler thoughts of soft indulgence, he feels in his inmost man, "This is no flattery."

The intellect of the people bears analogy to this outer life. It may have no wide range, there may be no versatility of genius, but the Warwickshire artisan brings to the foundry or the loom a mind so concentrated on the work before him as to constitute him a workman unsurpassed by any county in England. The language spoken by the people is essentially strong and truthful. They tell you their sorrows and their joys with a wonderful open-heartedness, and with a power of thought and freedom of language I have never heard equalled. Church and state are dear to a Warwickshire man in proportion as the parson "shows a good light," and the master gives a "fair wage for a fair day's work." But I have wandered away from Warwickshire lanes to Warwickshire people—a short digression—for many

a white-washed cottage nestles beneath the spreading trees in the lanes, and many a welcome from old friends has greeted me as I appeared trowel in hand.

The Warwickshire lanes abound in *Polystichum aculeatum*. It may be found side by side in its varieties of *lobatum* and *lonchitidoides*, but the latter is more rare. *Polystichum angulare* is also to be found. It may be known from *aculeatum* by the darker green of the fronds, by their stiffer habit of growth, and by the prickly nature of the pinnæ. It is necessary to study both Ferns together to be able to decide with certainty at a glance which Fern is before you. *Ophioglossum vulgatum* grows in the meadows of Warwickshire; but the Adder's-tongue is not happy in cultivation, and it is so common that, like *Pteris aquilina* or common Bracken, few care to cultivate it. I transplant *Ophioglossum* yearly to the fernery, but only to see it yearly devoured by slugs. Eventually I discarded from the fernery nearly all of the large Ferns, planting them in good rich soil in the walks leading to the rockery. *Filix-mas*, *Filix-femina*, *Lastrea dilatata*, and the *Scolopendriums* grow well and handsomely in the shade—indeed they may be said to prefer it.

One of the handsomest foreign Ferns for out-door culture is the *Struthiopteris germanica*. Its perfect vase-like form of tender green, throwing from the centre rich-looking spikes of fruit, contrasts well with the dark robust *Filix-mas*, and forms a beautiful object for the eye to dwell upon.

Nothing but Ferns should be planted in a fernery, and great care should be taken to make good drainage at the bottom of each separate space allotted to a Fern. In planting them you must be careful that a large Fern does not overdrift a small one.

On my return from Scotland I planted *Septentrionale* in an open space in the full sunshine, with good earth and drainage, and it has flourished well. I put a specimen of each *Cystopteris* in the fernery, turning the others into a border for a flat fernery I made without rock. They grew well in this situation, increasing rapidly, so that in a couple of years I could have stocked three or four ferneries.

Dryopteris and *Phegopteris* I planted on the lower range and at the sides of the rockery; but they are troublesome in cultivation, the creeping roots finding their way into each other's houses, and becoming a confused but always beautiful tangled mass of green.—*FILIX-FEMINA*.

MY ORCHARD-HOUSE.—No. 12.

ABSENCE, on a visit to those districts of France which are most celebrated for their fruit culture, has caused an intermission of some weeks in these papers. The time, however, has been busily occupied in examining into matters which, however important to the amateur, he cannot always command the opportunity of seeing for himself. Having no object but to be useful to my brother amateurs, it shall be my future care to present to them the results of these notes on fruit culture in France. The day has, happily, long gone by when to allude to the works of any of our neighbours was viewed with suspicion and dislike. Though England is confessedly at the head of all in her horticultural triumphs, she never could have attained to this had she despised the progress made in other parts of the world, in similar pursuits. Each nation has its peculiarities and special proficiencies, and the speciality of the Englishman is that he is not above learning from even uncivilised communities. Though considered abroad as the most prejudiced of mankind we are really the only cosmopolitans. If these things really be so, they are the secret of our success in every great undertaking. And when we consider how much horticulture, as a practice, and not merely as a theory, is influenced by differences of climate, soil, and locality, it is evident that there is very much to learn still, and that every humble contributor to the general stock of knowledge has his appointed post in the work.

Looking also at the subject from another point of view, each individual effort which is made to promote free exchange of thought among neighbouring nations conduces to the growth of good feeling and peaceable dispositions. It is this thought which makes many of us rejoice in the spread of horticultural pursuits, for we know that they civilise men,

and calm angry jealousies. My brethren, the clergy of England, know this well, and they are especially unanimous in recommending a taste for these homely and quiet objects. No one feels this more than the amateur in foreign lands, for he is sure of a kindly welcome when he presents himself as an inquirer. A bond is at once established between utter strangers, and it is his own fault if the traveller fail in bringing back some new and valuable information. Having myself, from ill health, spent much time on the continent, I can testify to the truth of these things, and having derived many advantages therefrom in former times, it was very interesting to revisit these localities after a lapse of seven or eight years. Perhaps, some notes made may interest my brother amateurs.

The places visited were Angers, Chartres, this year, and Montreuil (near Paris), last year. We may take these places as types of the most advanced French cultivation. They are essentially different in their "school," as it is there termed, but present nevertheless points of resemblance. The practice at Montreuil is that which most resembles good English open-air pruning (I speak of the Peach at present); that at Angers differs somewhat from it, but both are essentially "long pruning." At Chartres, on the other hand, is a "school," about a quarter of a century old, founded and directed by M. Grin, ainé, which advocates the very closest pruning. That of Orleans is a development of this system, and has numerous adherents. As it is proposed to place these matters on a larger scale before the readers of this Journal, our remarks here shall be confined to Chartres.

Chartres is a town situated on the western line of rail, and not far from Paris. It is very accessible to any amateur, and well worthy of a visit. The summer climate is very favourable for fruit culture, but the winter is cold, and the soil, generally, not deep, nor abounding in rich matter. Science, therefore, has to be called in aid here as well as in England, and from what I heard from other quarters, horticulture, until M. Grin showed the way, was at a low ebb. This kindly-disposed and intelligent gentleman has a small property of his own close to the public gardens, which are beyond the promenades. It is necessary to remember this, as the French are not clever at directing Messieurs les Anglais. Having, however, managed to overcome these apparently insurmountable difficulties, we were amply rewarded. Indeed, few things have given me more pleasure of late than this visit.

The system advocated by M. Grin lies at the basis of all orchard-house pruning. It consists mainly of extremely close summer pruning, in the simplest and most rational way possible, and as M. Grin has devoted nearly his whole life to the study of fruit trees, and notably of the Peach, and has inaugurated a novel and a successful system, amateurs will be especially interested to hear something of it. M. Grin has confided to me the task of representing his opinions to the English public, of which he speaks highly, and as this system is, in the main, similar to that described in my own work, "Cordon Training," published in 1860, this may serve the better to describe it.

As these lines are not written for the great and learned gardeners of the nobility, but simply for amateurs and inquirers, I may here again say that all Peach pruning consists of "long pruning," and "close pruning." M. Grin is the person, undoubtedly, who has introduced this last system, and who has perfected it. So novel a revolution has caused a storm of angry contention among French cultivators. While it has been assailed and criticised by some, others have endeavoured to supersede it by introducing systems developed from a similar basis. These systems have, nevertheless, their own merits, and shall be considered in due time.

I myself, have long been convinced of the value of close pruning. Having, in 1857, heard of it from M. Leroy, of Angers, while I was there attending lectures on fruit culture, on returning home I immediately cut back very closely all my Peach trees in the open air, and have continued up to the present time to grow very fine and regular crops from trees closely spurred. Not one of the shoots on these spurs have been tied-in. They have simply been pinched-in in the summer to three leaves, and several shoots being formed on each spur, one or two were selected in the winter to bear the fruit, and those not wanted were cut back to two eyes

to obtain fresh wood. I took the idea from hearing about M. Grin's work, as I said, but had never seen his trees till this year. They therefore differ from my own, and are very beautiful specimens of Peach training. I doubt if any one has ever seen finer in every way than those in the public gardens under M. Grin's charge. They were perfect in form, either as horizontal or oblique cordons, healthy, and very fruitful.

M. Grin, however, pinches during the summer to two leaves, and obtains very fine bearing shoots quite close to the branch. This is closer pruning than my own. But the dominant idea is similar, and it will be at once evident that this "close pruning" is the very thing we require for orchard-house trees. In fact, no other can be practised, and I may be allowed to say, that in my opinion, it is far superior to the practice founded on disbudding. I hope to show this more fully at some future date. In practice orchard-house pruners have long ago dismissed "long pruning, or disbudding," as out of place. There is no room for the one, nor is the other needed, if we concentrate the action of the sap by a better and a more natural plan.

In the open air, by merely being careful to cut away forerights, and to tie in those shoots which are unruly (I do not, but it may also be done with much advantage), there is no reason why Peach trees should not bear as well on this plan, as they do in orchard-houses. The intelligent gardener of a friend, by merely adopting this plan after having seen my own trees, has obtained remarkable crops. In our gardens being satisfied with leaving one fine Peach for every 9 square inches, the crops every year are nearly always the same. In the house we take about double. I beg here to endorse what that "great gardener, Mr. Rivers" (as that worthy writer, "R. F.", calls him), says about not expecting continuous and heavy crops from trees in orchard-houses. They will bear fast enough if required; but no tree can stand this demand on its vitality. If we had houses in which to rest our trees—say every third year, this might be done.

Returning to the gardens at Chartres, we witnessed many fine specimens of Pear and Apple trees trained to horizontal wires in various handsome forms. Some Vines closely pinched in were also very promising. There is another idea to work out. As these matters have a direct bearing on the orchard-house question, which has now become so interesting, such remarks may prove useful.

Amateurs may be assured that the progress of these houses is watched with interest abroad. In those marvellous climates what might not a Rivers effect! Prejudice and a fear of outlay alone keeps cultivators on the Continent from producing fruit rivalling that of tropical regions. I have heard most of the objections raised by foreigners to this, but they have but little weight. Nevertheless, appliances to lessen the evil effects of abrupt atmospherical changes, are now recommended in the best works. Tiffany screens will soon be general, temporary glazed coverings have always been used, and what are orchard-houses but these ideas elaborated?—T. COLLINGS BRÉHAUT, Richmond House, Guernsey.

VINES IN POTS IN AN ORCHARD-HOUSE.

I WISH Mr. W. Paul would inform your readers whether the Grapes which he so usefully tested in an orchard-house, were confined in pots, and whether the house was heated.

I have always found it difficult to grow Grapes in pots in an unheated house. The Vine has naturally long rambling roots, and however careful one may be in giving good drainage, and having a light soil, yet the Vine, unless assisted by bottom heat, is so slow in fully occupying the soil, that this becomes compressed and soddened by the necessary watering. In the open ground Vines seem comparatively indifferent to soil and drainage. I have just had to dig up some St. Peter's planted in the border of an orchard-house near a stove about four years ago. Several large roots, leaving the well-made inside border and the warmth of the stove, made direct for the outside garden ground, which was soddened by drip from the roof. The Vines ripened, however, capital crops.—S. B.

[In reply to the above, Mr. Paul has obliged us with the

following:—"The Vines were grown throughout in the temperature of a cool viney, which was kept somewhat close while they were setting. There was no bottom heat, and not a root left the pots. The latter were full of roots when first introduced, the plants having been grown from eyes in pots last year.—WM. PAUL, Nurseries, Waltham Cross."]

GROWING CERTAIN ALPINES IN MASSES.

MR. ABBEY really makes my mouth quite water. He talks of "beds of plants" looking "lovely" and "beautiful"—of plants we unlucky amateur gardeners can hardly meet with, and still less grow when we have them. Fancy "beds" of *Linnæa borealis*, *Primula nivalis* and *cortusoides*, *Silene acaulis*, *Soldanella alpina*, *Cortusa Matthioli*, and double red Primroses! Will Mr. Abbey tell us how we are to have beds of such delightful little rarities, and in what county he has seen them? Pray give a place to this note if you have room, that brother amateurs may state their experience.—A. R.

[A. R.] has drawn on his own imagination, and then placed the results to my account. He says I talk of "beds of plants" looking "lovely and beautiful." Now it does so happen that the words "lovely and beautiful" are not used by me at all in speaking of the beds of plants named by "A. R.;" but "fine beds" in relation to *Soldanella alpina*, "neat mass" as regards *Silene acaulis*, and "prettier bed" in respect to double red Primroses. It so happens, also, that the plants named can be grown successfully in our climate (and what is it we cannot grow in England?) and may be had for the purpose named either by purchase or otherwise; that purpose being the cultivation of them in quantity, so as to show them in large or small masses, in places where they would be more appreciated because more seen than they are now in some out-of-the-way corner, where they are stifled for want of fresh air, and their beauties hidden.

Now as to the how and where.

The first plant named by "A. R." is *Linnæa borealis*, a dwarf trailing alpine allied to the Honeysuckle, with pink and white fragrant bells or trumpets. He can procure this for 9d. or 1s. from several of the nurserymen who advertise in our columns; and if he like to give an order for a hundred or thousand he can have them, I have no doubt, within twelve months; or if he likes to go to one nursery they will show him "lovely and beautiful" not beds, but masses of this, and many rare though curious and charming alpines from every region of the globe, besides many other little rarities. I will suppose that "A. R." has this plant in sufficient quantity to form a bed; if not, it will not cost much to obtain sufficient plants, and he may raise the bed considerably with rock stones, and fill in the interstices with sandy-loam and peat, mixed with one-half of small stones. On this place a layer of the compost about 3 inches thick, and set the plants in it, so that they may cover the surface, and if they are of the size of many that I have seen it will not take many to do so. This mode of planting may be carried out now, and it will be found a much better plan for one-half the alpines than keeping them coddled in close frames. The plants will not need anything all the winter through; and if the bed is a permanency it must not only be elevated, but the soil should be drained, and neither allowed to become very dry in summer nor baked by strong sun. Some slight protection, as a little moss, should therefore be given, and if the plant in question does not receive the sun from 10 A.M. to 3 P.M. after May it will bloom most of the summer. I did not say that *Linnæa borealis* made a "lovely or beautiful bed," because I knew it bloomed quite late enough to be employed for spring gardening; but I have seen it occasionally bloom early, and in a mass too, and on that account it had a place. For such a purpose it should be grown in shallow pots or pans well drained, in the compost already named, and be plunged in the beds during the period of bloom only, and when that is passed be placed in an east border.

Soldanella alpina, *Primula nivalis*, and *P. cortusoides* may be had for making fine beds, and *Cortusa Matthioli* also if the plants to do it are at command, and they can be had at any of the leading London or provincial nurseries for a mere

life. The situation should be open yet sheltered, and the plants grown in pots when not in the beds, though that is not imperatively necessary. If in pots they should only be plunged in the beds during their period of bloom, and when done blooming be removed to an east or other border where they will not receive much sun from 10 A.M. to 4 P.M. Grow them in such a border—namely, a cool border, where they may receive the morning sun before it becomes too powerful, but to be protected from it during the hotter part of the day, let the subsoil be well drained, and use a compost of sandy turf loam and well-decayed leaf mould or peat in equal parts. Water should be given copiously until the growth is perfected, when half an inch of river sand or silver sand may be placed around the neck of the plants, but it is a good practice to do so before the dog days begin. With this sand around the necks of the plants copious waterings are not necessary, but a slight sprinkling should be given on the evenings of hot days. The plants are best in rows from 6 to 9 inches asunder, sufficient room being allowed in the row to prevent their actually touching. In this position they may remain until they show signs of growth, when they may be taken up with balls and planted in sunny but sheltered situations in the flower garden in soil prepared for them. When done blooming they may be returned to their old quarters, divided if it can be done, and there they may remain until removed to their blooming quarters again; or if the soil is very wet, they may be potted in September in wide shallow pots, using the compost named, with perfect drainage, and taking them up carefully. After potting place in a cold frame slightly protected from frost, keep comparatively dry, and guard against snails and slugs, which are very fond of the flower-buds. It is hardly necessary to say they should have all the light possible, and on all favourable occasions be thoroughly exposed to the air.

I have seen most of the above grown in this manner by the square foot, and *Soldanella alpina* by the square yard, by an old gardener when I could not even pronounce such names; and if they could be grown successfully by a man that could hardly write his name, yet who never saw failure in a little difficulty, what is to hinder our doing so now? So little were the Soldanelas thought of but a few years ago, that they were sold at 2d. each by the gardener in question, now deceased. I may also state that I have had fine beds of *Soldanella alpina*.

As for *Silene acaulis*, plant it either in a border in sandy peat and loam, or in a pot well drained, and afford the treatment commonly given to alpines, and it will be ready to do its work when called upon—that is, when in bloom the pots to be plunged in the places desired. Any one can have a plant of this from any nurserymen for 9d., and have a stock in a short time by dividing the roots either in autumn or spring, potting, or planting in a sunny border, and on rock-work or stones covered with a few inches of soil it grows well. I had fine masses of it.

Beds of double red Primroses any old woman can have, and I leave "A. R." to find out some neat cottage garden where the flowers are mostly known as Gillivers (Wall-flowers), Stepmother (Pansies), and Polly Aunts (Polyanthus), and he may possibly be told that double red Primroses will grow anywhere, and yet he will find them in a corner receiving the morning sun and but little during the hotter parts of the day, and that they are divided at all periods of the year just when the fit comes on her to trim up the garden, or give a slip to a friend, which is sure to be when the plants are in flower. Double red Primroses are in cottage gardens in patches large enough to fill the half of a modern flower-bed.

As an example of the care necessary to grow double red Primroses, before I was in my teens I planted a root in a corner of my father's garden close by a well, and this has continued to grow in the same place, so that my son has dug round it like me in his youthful days, and I have no doubt that another generation may do the same. It is now one immense patch, and beside it are many of the different Primroses, both single and double, that were put there by myself, and now remain, people yet stopping to look at the little garden corner over the Quick hedge by the well, and admire the beauties there exposed to view during the days of spring. In that little corner I planted numbers of common Primroses under the supposition that they would

change their colour, as I was told they would with the bees inoculating them.

Now, will "A. R." explain why when the soil of a long plantation of trees was planted with common Primroses out of the fields, a number of them on the brow of a dry hill became of a rosy purple colour in a few years, and this almost without exception, whilst those in the hollows or moister parts are every one of the usual Primrose colour? Also, how does it happen that the common sweet Violets when planted there are scentless in the following year? The soil is hazely loam on gravel.

At Wentworth House, the seat of Earl Fitzwilliam, some of the plants referred to might have been seen in sufficient quantity to form beds, being as they were plants to which Mr. Henderson, the late gardener, was very partial; and not only these, but many others both Alpines and Filices, I have noted in the counties of York, Cheshire, Lancashire, Somersetshire, Middlesex, Kent, and Surrey, in all cases cultivated in duplicate; and when they can be grown successfully as single specimens, what is to hinder their being grown in sufficient quantities to form masses?

The reason they are not now grown in quantity is, the fashion has lately been for a class of gaudy trumpery, and such plants have absorbed all the care and attention that was formerly paid to alpine and herbaceous plants, resulting in the latter being left to dwindle away, and now that there is a reaction about to commence, and a return to favour of our good old favourites, people start up and say they cannot be successfully cultivated in England. Surely we are not less intelligent, nor less clever than gardeners were thirty years back, and who had many plants that no one now a-days knows anything about. I say, if the present rage for tender summer bedding plants continues to drive out of cultivation all plants that are in the least difficult to cultivate, as they have done very many of the old ones, then the time has arrived for those who write for the public to set their faces against the monotonous features which our gardens exhibit at the present time. In doing so it is not unlikely that mistakes may be committed in noting plants not generally in cultivation as suitable for massing, which through our comparative ignorance of them may not be suitable for such a purpose. But what if we do name any that are not suitable, if only attention be directed to some such plants a liking will spring up for them, and mistakes will soon be rectified. Many of the plants named by me are suitable for forming masses in the flower garden, and none are unsuitable that I have said to form fine beds or masses, and I do not fear the issue of their trial, convinced as I am that what could be grown successfully in former times in herbaceous borders, can now be grown with the same care, and the same amount of success. Of that number will be found *Soldanella alpina*, *Silene acaulis* (though S. Schaffii, a near ally, may be thought more of), and double red Primroses. I am delighted to find that attention is being directed to these exquisite alpine and herbaceous plants, which have been too long neglected by nurserymen.—G. ABBEY.]

MISMANAGEMENT OF THE ROYAL HORTICULTURAL SOCIETY.

As a very old Fellow of the Horticultural Society I fully agree with your remarks upon its present mismanagement.

I would beg leave to notice the gross inattention to the state of the plants distributed by the Society. A short time ago I received some which were awarded to me by ballot, and my gardener told me they were so infested with mealy bug and scale that he would not upon any account have ventured to place them near other plants.

I would also remark, that if there are any plants of any rarity to be distributed, they are so few that it is a hundred to one that one gets any of them; indeed, generally they consist of plants of the commonest and most useless sorts.—A FELLOW OF THE R.H.S. FOR MORE THAN THIRTY YEARS, Brighton.

THE ILLUSTRATED BOUQUET.—The eighteenth part of this beautiful serial, published by Messrs. E. G. Henderson & Son, at their Nursery in the Wellington Road, contains excellent

portraits of the hybrid varieties of the Columbine, *Aquilegia glandulosa* and *Skinneri*; *Rhododendron Countess of Had-dington*; variegated *Pelargoniums Lucy Grieve* and *Rosette*; *Gomphia decora*; hybrid *Pink*, *Garibaldi*; and *Genista prostrata*. The illustrations are excellent and the information relative to each useful.

BIRMINGHAM FRUIT AND CHRYSANTHEMUM SHOW.

CONCURRENTLY with the great show at Bingley Hall, the Handsworth Horticultural Society, an old and well managed institution, held its annual Exhibition in the noble Town Hall. Formerly this Exhibition was held in June, but the Society most wisely decided on changing the time to the cattle show week, when the great influx of visitors afforded the prospect of its proving more remunerative.

The subjects composing the exhibition were arranged with great taste on six tables running the entire length of the Hall, whilst a brilliant bank of Chrysanthemums placed beneath the organ, and flanked on each side by a Holly tree in berry, faced the visitors on entering.

The Chrysanthemums, both large-flowering and Pompons, did great credit to the skill of the growers, particularly those of Mr. C. J. Perry, of Castle Bromwich, Messrs. T. Ryland, Milward, and Fewkes. Among the large-flowering kinds were excellent examples of Annie Salter, Golden Christine, Prince Albert, Alfred Salter, Vesta, Lady Hardinge, Chevalier Domage, and other well-known sorts. A very fine specimen of Christine was exhibited by T. Ryland, Esq., and Golden Christine, from Mr. Milward, was very good. For collections of nine, the first prize was taken by Mr. C. J. Perry; the second by Mr. Ryland, who also had the first prize for six, and for the best single specimen. For six, Mr. Perry was second, and for single specimens, Mr. Milward occupied a similar position.

If anything, the Pompons were still better than the large-flowering plants; and of the three kinds of Cedo Nulli—namely, the old, Lilac, and Golden, there were several excellent specimens contributed by Mr. Perry, Mr. Ryland, and Mr. Fewkes. Mr. Fewkes exhibited a very fine single specimen of the first-named covered with large blooms, and Mr. Perry, Cedo Nulli, compactly and well grown, and likewise in beautiful bloom. Of other kinds there were good examples of Mrs. Dix, blush bordered with rose, Danæe, Andromeda, Salomon, Hélène, and Modèle. Mr. F. Chitty, gardener to T. Webley, Esq., sent handsome plants of Bob, Miss Julia, and Bijou de l'Horticulture, with which he took an extra prize offered by Mr. Perry.

Cut blooms were not equal to what we have seen at the metropolitan shows, being less in size, and some had evidently been taken from plants not grown for the purpose. Mr. George, of Stamford Hill, and Mr. Tomlin, contributed good stands, in which most of the leading varieties were represented.

Of Primulas, excellent plants were shown by Messrs. Chitty, Ryland, and Greaves, and the new Fern-leaved kinds by Mr. Vertigans, the latter also exhibiting a good collection of Celosias. A large plant of *Poinsettia pulcherrima*, from Mr. Chitty, was much admired.

The show of fruit was very good, particularly that furnished by Mr. Perry, Mr. Evans, gardener to C. Newdegate, Esq., M.P., Mr. Hargreave, and Mr. Pluck, of Jersey. A collection of twenty-four kinds from Mr. Perry, consisted of a Smooth-leaved Cayenne, of about 7 lbs., a good Queen, a Melon, Barbarossa Grapes, Pomegranates, magnificent Chaumontel and Beurré Diel Pears of foreign growth, besides several dishes of other kinds, Cox's Orange Pippin, very good; Alfriston, large, and some other kinds. In a collection of twelve also shown by Mr. Perry, were two bottles containing Pears, but these being much larger than the necks of the bottles, most of the visitors were puzzled how they could have been got in whole. Of course, they had been grown in the bottles. Large Reinette du Canada Apples, Sarasin, a good stewing Pear, well-ripened Muscat and Black Hamburgh Grapes, and Webb's Prize Cob Nuts, were also shown in this collection.

Good collections also came from Mr. Stevens, and Mr. Evans, and a large bunch of Barbarossa Grapes from Mr.

Craddock, gardener to Lord Willoughby de Broke, as well as good examples of Lady Downes', and other Grapes.

In dessert Pears, some very fine dishes were shown by Mr. Perry, particularly of Chaumontel, Easter Beurre, Beurré Diel, and Beurré Clairgeau; Huyshe's Victoria was also in one of his collections. Mr. Pluck, of Jersey, had also several fine specimens, as well as Mr. Royd, and others.

In stewing Pears, Uvedale's St. Germain was shown in several collections as Belle de Jersey, and the others consisted of Verulam, an excellent stewing Pear, Poux de l'Evêque, very showy, and Governor of Boulogne, a yellowish green, covered more or less with reddish russet; Cattillac, Gilgil, Bellissime d'Hiver, Pound Pear, Sarazin, &c. The principal prizes both for dessert and kitchen varieties, were taken by Messrs. Perry, Hargreave, and Pluck.

Of Apples, both dessert and kitchen, there was also a good display, comprising good examples of Blenheim Pippin, Court Pendu-Plat, Cox's Orange Pippin, and many other sorts, whilst of those for culinary purposes we noticed large fruit of the Alfriston, Mère de Ménage, Cellini, highly coloured, Dumelow's Seedling, and other well known varieties.

In a collection of Gourds from Mr. Perry, who was the largest and most successful exhibitor, there was a ripe Vegetable Marrow of 14 lbs. in weight, and among the ornamental kinds, one called Lurline, was very prettily marked.

Altogether the Show was creditable to the town; the setting up of the plants could hardly have been improved, and the general arrangements of Messrs. Perry and Tye, the Secretaries, were excellent.

BIRMINGHAM ROOT SHOW.

SUCH a subject may seem out of place in the horticultural columns of this Journal, but it is not our intention to trench upon the domains of the sister art of agriculture, by canvassing the merits of cattle and sheep and pigs, of ploughs and scythes and clod-crushers, or of thrashing-machines and winnowing-machines and turnip-cutters; but there were some exhibitions at the great Midland farmers' meeting just held, which were deserving of mention. The stand of Messrs. Sutton, of Reading, was in particular well worthy of inspection. It formed a neat centre to the end gallery of Bingley Hall, and besides a great variety of roots there was a collection of Grasses at the back amounting to about two hundred sorts, consisting of the beautiful Pampas Grass, so ornamental on lawns and by the side of water, the various Poas, and other ornamental and useful Grasses. The roots were of large size and weight, notwithstanding the dryness of the season; among them were between thirty and forty varieties of Potatoes, the Student Parsnip, Intermediate Carrots, Mangolds, White Globe Turnip, and Champion Swede, the former a quick-growing early kind, the latter one which attains an enormous size, and excellent for feeding. A root of this grown by H. Crawshaw, Esq., of Newnham, Gloucestershire, weighed 25 lbs. Giant Tankard was another quick-growing heavy Swede. Kohl Rabi though not strictly speaking a root, is classed as such, and has been found this season to withstand the drought better than Turnips and Swedes. Some examples of the Green and Purple kinds were very large and solid, both in Messrs. Sutton's and other stands. Of course, when to be used as a garden vegetable it should be taken when very young, and in dry seasons it may be advantageously grown in case of Turnips failing.

Seeds of two early Peas were also shown in this stand. One, Ringleader, is stated to grow 2½ feet high, and to be very early and productive; the other, Sutton's Longpodded Tom Thumb, grows a foot high, and is said to be equally early and more productive than the old Tom Thumb, bearing pods double the length of that kind.

Messrs. F. & A. Dickson, of 106, Eastgate Street, Chester, had also a large stand, in which were specimens of forest and ornamental trees and shrubs, Lawhead Green-top and other large Swedes, Mangolds, some very fine Altringham Carrots, Dickson's Mousetail Turnip, a yellow garden kind between Orange Jelly and Yellow Stone; also, Dickson's "First and Best" Early Pea, said to be extremely early, coming into bearing a week or ten days earlier than Dillistone's Early Prolific, very productive, and of fine quality.

From Messrs. James Dickson & Sons, 102, Eastgate Street,

Chester, came Piceas, Wellingtonias, Osmanthus, and other trees; Manchester Champion Red Celery, seeds, and roots; and from Mr. Perry, of Banbury, seventy-two White Spanish Onions weighing 54 lbs.; twenty-six sorts of Potatoes, Carrots, Turnips, and Parsnips. Finally, in the strictly agricultural portion of the Show there were fine, large, clean roots of Altringham Carrots from G. Foljambe, Esq., Osberton Hall, Worksop, who also took the first prize for the best Round Potatoes with Malvern Relish, a rough-skinned red, which looked as if it would boil very mealy. The first prize for Kidney Potatoes went to Mr. Robinson, of Shaw House, Melbourne, Derbyshire, for King of Flukes.

ORCHARD-HOUSES.

LIKE many others interested in orchard-houses, I have watched with interest the controversy which has so long been going on in the pages of this Journal. Much has been written against the system of growing fruit trees in pots, and a good deal in its favour; but I think, as the subject is getting better understood, and the causes of failure and shortcomings are being investigated, it is pretty evident, notwithstanding the various attacks made upon the system, that fine fruit, and large quantities of it, may be grown in pots.

It would be well if those who succeed in producing good crops of fruit from pot trees were from time to time to record their successes in this Journal for the encouragement of those who fail; and if those who are not so successful were to detail their shortcomings with the mode of treatment they have been practising, then their more successful brethren might point out where mistakes had occurred, and help them to a better mode of treatment.

I am surprised, on reading the contributions against the pot system, that men who shine so brightly in horticulture should condescend to attack a system they have never tried, because their old theories and deep-rooted prejudices will not suffer them to believe that success can attend it. Many object to growing fruit trees in pots in consequence of the time and trouble required in attending to them. May I be allowed to ask, Can a house of Orchids be grown without care and attention on the part of the professional gardener or his assistants? Or is it possible for the amateur to bring to perfection a pitiful of Auriculas without time being spent in their management? And do Orchids, or Auriculas, or Roses, or even bedding plants, with all their gorgeous splendour, repay the cultivator better than fruit trees in pots? With regard to that beautiful harbinger of spring the Auricula, it, perhaps, cheers its admirers with its fragrant flowers at the most from three to four weeks in the year; whereas a Peach, for instance, affords a great amount of interest and pleasure for at least six months out of twelve. With the first genial sunshine and soft breezes the buds begin to swell, then the flowers expand; and what a lovely sight is a housefull of Peach and Nectarine trees in full bloom! what a diversity of colour! Then there is the setting of the fruit, its progress week after week, its final swelling and colouring—in short, in the whole process from the first swelling of the bloom-bud till the fruit is laid on the dessert-table, there is not a day without interest to the cultivator.

I gave an account a little later than this last year of a small orchard-house under my care, and in reviewing the previous season's labour I was enabled to speak favourably of the success which attended my efforts. In reviewing the season of 1864, and comparing my notes with last year, I find that some of our pot trees have borne more than double the quantity of fruit they did last season, and I can confirm the statements made in this Journal that the trees improve by age. All our Peach and Nectarine trees are in 13-inch pots (that is, 13 inches in diameter at the top, and 13 inches deep), and have yielded on an average about three dozen each; one Elrige Nectarine carried seven dozen of fruit, and brought them all to perfection. A first-class gardener declared he was sending fruit of the same kind to the table from wall trees under glass, and no finer. The thinning of the fruit was done at different periods, and as many as nine dozen at a time taken off. The same tree carried six dozen last year. A smaller tree of Elrige carried four dozen, and the fruit was very fine; Hunt's Tawny five dozen. Every amateur should grow this beautiful variety, though it is a little

deficient in flavour; it contrasts well with all other varieties, especially the Duchess of Oldenburg, is early and very productive. Early York, one of the best early Peaches I ever saw, and the admiration of all visitors, was thinned to two dozen and a half; it cannot be too highly commended for pot culture. Acton Scot was allowed to carry three dozen and a half; though a useful variety, and well adapted for pot culture, it will have to yield the palm to the last-named sort. Royal George, a small tree, bore two dozen; the fruit from a wall in the same house, and the same variety, was not so fine as that from the tree in a pot; other trees were in like proportion. I have weighed none of the fruit this season, and only measured two Peaches, one was 8 inches and the other 9 inches in circumference.

With regard to the ripening of fruit, a subject on which intercommunication has been invited by your Guernsey correspondent, I find on comparing my notes of the present year with those of the last that the period of ripening has advanced about ten days. Acton Scot Peach, which was ready for table last year by the 11th of August, was ready for use this year by the end of July. Early York was not ready last year until the 12th of August, this year it was so by the 3rd of August. Royal George advanced seven days, Angers Large Purple ten days; Pitmaston Orange, Duchess of Oldenburg, Hunt's Tawny, Violette Hâtive, and Elrige Nectarines have each ripened from seven to twelve days earlier than last year. The whole of our Peaches and Nectarines were more than ten days sooner this year than last. We began last year August the 10th, and had done by the 12th of September. This year we began by July the 25th, and had finished by the 2nd of September; but I attribute their early ripening to the increase of sunshine, which has prevailed this year. We generally have in this neighbourhood (Biddulph, the northern extremity of Staffordshire), a good deal of gloomy weather, with a large amount of rain, and then, to correct the temperature, we apply a little fire heat, always accompanied with plenty of air. This season we have had abundance of sunshine, therefore but little fire heat has been required. An abundance of air was always given during the progress of the ripening of the fruit, and the house was never closed until the fruit was all gathered: hence the fruit was perfect in flavour. Our trees at this season look better than they have done before, the wood is well ripened and short-jointed, the buds are numerous and very prominent.

I consider the numerous miserable failures detailed by the opponents of the pot system to result from lack of attention or want of skill, or both; for where attention is given to minute points success is sure to be the rule. In order to arrive at success it requires constant care and constant watchfulness. The trees should never suffer during the growing season for want of water, taking care that the soil is not sodden. Occasional applications of manure water are also beneficial. The syringe should be in constant use, not a mere sprinkling of here and there a leaf, but a thorough good dose; it helps to keep the respiratory organs of the trees healthy, and the red spider has no chance to exist. I have scarcely seen a spider on our trees this season, and I attribute its absence to the free use of the syringe.—*QUINTIN READ, Biddulph.*

COMPARATIVE PRODUCTIVENESS OF POTATOES.

In your Number for November 1st some results were given of experiments on the productive qualities of various sorts of Potatoes grown at Prescot, in which Paterson's Seedlings made a very conspicuous figure. A friend of mine living near me has just concluded a similar set of experiments with equal or greater care, but with different results. I forward them to you, that you may, if you please, give your readers an opportunity of comparing them.

I must premise that the quantity of land set was seven-eighths of an acre, and the crop the first from reclaimed moor land. It was broken up in the spring and summer of 1863, and the turf burnt. This spring it was half-manured with stable dung, and received, in addition, 10 cwt. of fine bones, which had been mixed in December with some of the burnt ashes, and 3 cwt. of guano, also mixed with ashes, was given at the time of planting. They were planted in rows 3 feet apart, from the 21st to the 29th of April, and

taken up in the second week in October. The result is seen in the following table. The "load" is 12 pecks—the peck 20 lbs. by weight. The land is situated in North Derbyshire, on the lower measure of the millstone grit.

Sort set.	Quantity set.	Total crop.	Return.
	load. peck.	load. peck.	
Early Ashleaf Kidney	0 4	1 1	3.25
Lapstone Kidney	0 6	2 8	5.33
Flukes	3 1½	20 2½	6.6
White Rocks	1 0	9 11	10.0
Protestants	2 0	23 9	11.87
Paterson's:			
Irish Blue	1 0	3 9	3.75
Goliath Kidney	0 2	0 9½	4.5
Paterson's Red	1 0	4 11½	5.0
Victoria Seedling	0 1½	1 0½	8.0
Napoleon	0 2	1 7	9.5
	9 7	69 9	7.28

N.B.—The seed obtained from Messrs. Paterson direct.

Permit me to make a few remarks on these several results. In the first place, there is a difference between Paterson's Seedlings in the two series as compared together. In the Prescot list the Blue and Red sorts are far in advance of the Victoria and Napoleon. In the Derbyshire list it is just the reverse. In some trials printed and circulated by Messrs. Paterson themselves the result in this respect agrees with the latter.

Again, there is great discrepancy between the returns in the two series. In the Prescot experiments the Blue made a return of forty-fourfold. In the Derbyshire Napoleon (the highest) returned but nine-and-a-half-fold, whilst White Rocks and Protestants (local favourites, one originally from Ireland, and the other from Scotland) gave respectively a tenfold and twelvefold return. One cannot help seeing that some error has arisen, probably from the quantity tried being inadequate to a true aggregate. Obviously, the larger the quantity set, the whole crop being carefully weighed, the less likelihood of mistakes unwarly creeping in. In this respect the Derbyshire trials have a great advantage. The Messrs. Paterson took up only a single yard of each sort for comparison. This is wholly unreliable, as a very small error multiplied by the number of yards in an acre would amount to a great sum. That some such mistake has insinuated itself into the Prescot experiments seems certain from this—that the return claimed is altogether incredible. The quantity of seed for an acre at the ordinary distance, with rows 3 feet apart, we see is 32 bushels 2 pecks. A return of forty-fourfold, as given for Paterson's Blues, would amount to 1408 bushels, omitting the 2 pecks over, or more than 50 tons; in value more than £204 per acre at 3s. the bushel.

No doubt different Potatoes do better on different soils; but the only results from experiments of this kind that could be positively relied upon would require not only equal weights, but equal numbers of sets, and the larger the area the nearer would be the approximation to absolute truth.—*AGRICOLA.*

[We have the address of the clergyman who favours us with this communication. It is from such comparative experiments that truth is obtained, and it was with that object the Prescot experiments were reported to us. "AGRICOLA" is quite right in his remark that experiments on a large scale are much less liable to error than experiments on a small scale. Soil has much influence over the productivity of the Potato, but season and climate much more. It would be very satisfactory to have similar experiments instituted for two or three following years. The past summer was very hot and dry; would the same varieties give the same results if the summer were cold and wet? It is very desirable to know which variety will best endure such a season.—EDS.]

SOMERFORD PARK.

THE RESIDENCE OF SIR CHARLES SHAKERLEY, BART.

This lovely place lies about four miles to the west of Congleton, and is about five miles from the railway station. The country from Congleton to Somerford is uninteresting, and somewhat deficient in undulating scenery; but as I

passed along the road, I could not but admire the splendid fields of golden corn on either hand. Some had been already cut and carried, while the remainder was ready to succumb to the sickle.

We entered the park from the road leading from Congleton to Knutsford; it covers an area of about six hundred acres, and contains some noble specimens of timber trees, rearing their stately heads. Extending my rambles across the park in the direction of the gardens, I noticed to the left a beautiful lake, its extent judiciously concealed by bends and curves, and the banks planted with evergreen and deciduous trees. To the right lay the church (sustained at the worthy baronet's expense), encircled with masses of luxuriant green foliage. Arriving at the frame ground, the first things that presented themselves were some very old-fashioned houses. An old greenhouse was filled chiefly with Fuchsias, Ferns, and Lycopods, the latter two being great favourites with the lady of the house. Against the same wall was a range of Peach-houses and vineries, built sixty or seventy years ago, in the same style of architecture as our forefathers built hothouses. Notwithstanding the age of the Vines there were some good bunches of Grapes, the berries extremely well coloured, perhaps owing to the free ventilation between the numerous small squares of glass. That there had been a good crop of Peaches, and fine fruit, was evident from the remnant left.

Leaving now the frame ground, and entering the kitchen garden, properly so-called, the first object of interest was two newly-erected vineries, put up on the newest and most approved principles. The first house I entered was entirely devoted to Muscats; the Vines, only planted last spring, are at the back and front, and such canes for one year's growth I never saw. The second house had been planted two years longer, the first year the Vines were cut down in the usual way, last year they were allowed to carry two or three bunches, and this year they are bearing eight bunches each. It was the Grapes and flower garden that I more particularly went to see. I had heard a good deal of the latter, and my expectations were more than realised. The front of this house was planted chiefly with Black Hamburg Vines, with one Grizzly Frontignan, and one Muscat Hamburg. On the back wall were White Muscats, Buckland Sweetwater, Chasselas Musqué, and Trentham Black, and they were fruited nearly down to the ground. The Black Hamburgs were extremely fine, and in their culture evidently displayed a great amount of skill on the part of Mr. Silcock, the intelligent head gardener. Many of the bunches would weigh from 3 lbs. to 4 lbs. each. The berries were well coloured, a very important point in Grape culture, and I have seen but few, if any, to surpass them, either at Keele Hall, or Garston, two of the greatest Grape-growing places in the kingdom.

We have had many long treatises written on the formation of Vine-borders, so I will just give, in a few words, the composition of those here, which were inside the houses. No doubt when your readers hear of great success attending the culture of the Vine, or any other plant, they like to know the nature of the material in which the plant thrives so well. After the usual drainage, the borders consist of rich turf loam, pared from the surface of an old pasture about $2\frac{1}{2}$ inches thick, and allowed to remain in a compact mass previous to use, intermixed with ground bones, and a tolerable quantity of lime rubbish.

On leaving these houses I proceeded round the kitchen garden, and I noticed that the south wall not occupied by the vineries was covered with Peach and Nectarine trees in full bearing, and carrying a heavy crop. These, as well as all the other wall trees, have only been planted about six years, and yet nearly every inch of the walls was covered with fine healthy timber. The wall with a westerly aspect was planted with Peach and Apricot trees, the latter having borne a nice crop of fruit. On the east wall I noticed some fine Plums of the more choice varieties, while the north wall was furnished with Morello Cherries, and a most magnificent crop, such as hardly could be surpassed.

In the kitchen garden I also observed many cone-shaped Apple trees, near the edges of the garden walks, 6 or 8 feet high, and loaded with beautiful fruit. One small tree of Lord Suffield 3 or 4 feet high arrested my attention, I counted fifteen large Apples upon it, and took the dimen-

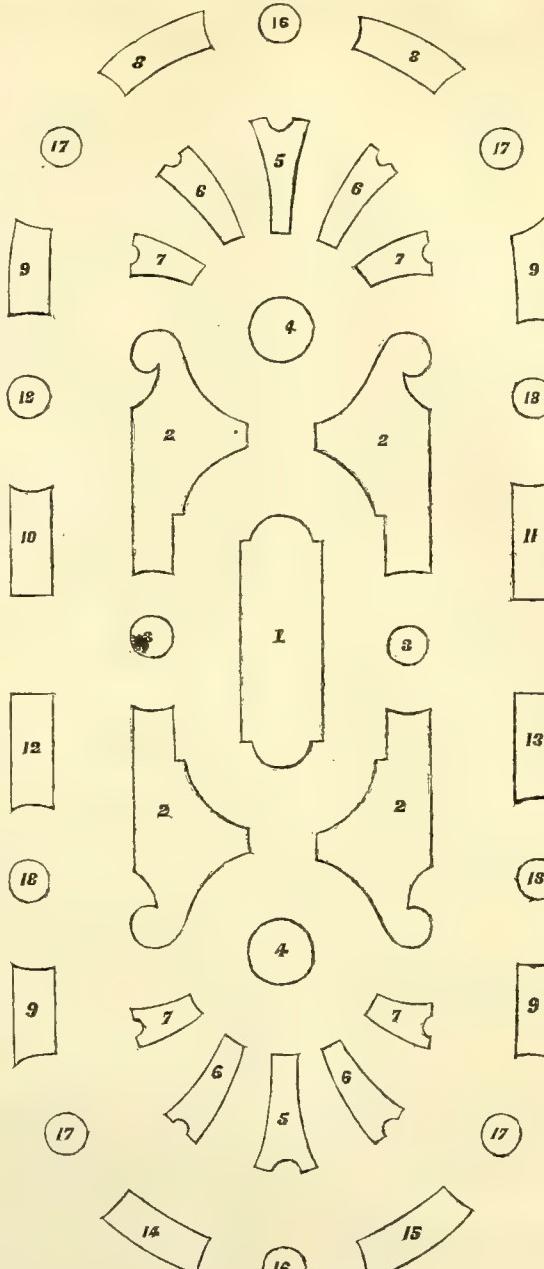

sions of one which was nearly a foot in circumference.

The Strawberries, I was told, had done remarkably well, Oscar having succeeded about the best. The plants were cleared of all runners and useless or dead leaves; but the system of mercilessly cutting off all the leaves was repudiated here.

The south and west walls on the outside of the kitchen garden were covered with choice Pears, and I particularly noticed such sorts as St. Germaine, Winter Crasanne, Belmont, Brown Beurré, Marie Louise, Beurré Rance, Ne Plus Meuris, Beurré Diel, Beurré d'Aremberg, and many others, all growing, if I may be allowed to use the expression, under the burden of heavy crops of fruit.

Leaving the kitchen garden and fruit department we turned to the left, and passed along a narrow walk screened from the sun's rays by lofty forest trees, with dwarf Laurels planted underneath, and from this walk we obtain pleasing views of the surrounding scenery. Down in the valley below the grazing cattle formed a pleasing feature in the landscape whilst wandering on the rich pasture land by the side of the river Dane, which meanders through the rich pastures of Cheshire, so noted for large cheeses. To the right may be seen in the distance a high hill called the "Cloud," which forms the extremity of a vast assemblage of rocky ridges spread over the northern portions of Stafford and Derby; it runs from north to south, and terminates in full view of the town of Congleton in a fine dome-shaped mountain, more than 1100 feet above the level of the sea.

A little to the right we come to an old-fashioned conservatory kept gay with some flowering plants. Some standard Fuchsias, 8feethigh and nearly as much through, looked well; also the fine old Orange trees, 9 or 10 feet high, which have occupied the same place for forty-five years. In front of this conservatory is a small flower garden, extremely cheerful and gay, and in which the plants were anything but the miserable objects some writers would make us believe bedding plants generally are this season. I only took down the way in which one of these beds was planted, and that was the centre bed, about 10feet square. The outer edge was Cloth of Gold Geranium, next to this were several rows of Rose Queen Geranium, with the centre Stella Nosegay; and I

Scale 24 feet to the inch.
FLOWER GARDEN AT SOMERFORD PARK.

- 1st Bed. Centre row Perilla nankinensis.
2nd. Calceolaria Aurea floribunda.
3rd. Tropaeolum elegans.
4th. Lobelia speciosa.
5th. Cerastium tomentosum; an edging all round.
2nd Bed. Geranium Bijou, edged with Purple King Verbena.
3rd Bed. Cloth of Gold Geranium.
4th Bed. Centre Perilla and Centaurea argentea, edged with Tropaeolum Eclipse.
5th Bed. Geranium Golden Chain.
6th Bed. Lobelia speciosa.
7th Bed. Geranium Stella Nosegay.
8th Bed. Verbena Firefly, edged with Cerastium.
9th Bed. Calceolaria Aurea floribunda, edged with Perilla.
10th Bed. Geranium Rose Queen, edged with Lobelia Paxtoniana.
11th Bed. Geranium Trentham Rose, edged with Miss Nightingale.
12th Bed. Verbena Bonny Dundee, edged with Lobelia Paxtoniana.
13th Bed. Geranium Carmine Nosegay, edged with Heliotrope Miss Nightingale.
14th Bed. Geranium Stella Nosegay, edged with Lady Plymouth.
15th Bed. Geranium Punch, egd. with Mangles' Variegated.
16th Bed. Gazania splendens, with Humea elegans in centre.
17th Bed. Geranium Alma, edged with Verbena Ariosto.
18th Bed. Mignonette, Humea elegans in centre.

have seen nothing in my rambles this season to equal Stella for beauty. This garden is kept gay in the spring, on the Cliveden system of spring flower gardening, with such things as Tulips, Wallflowers, Anemones, Forget-me-not, Lasthenia californica, Limnanthes Douglasii, &c.

From this lovely spot we wend our way along the pleasure ground by the north-east side of the mansion to the front, and here an unrivaled blaze of floral beauty at once bursts upon the view. In front of the mansion is a broad terrace-walk, and in front of that a sunk-panelled flower garden. This is but the second year of its being planted, it having only recently been laid out by Mr. Silcock, and its ornamental appendages are not yet completed. It looked extremely well. All the beds were full to overflowing, and when the sun's rays fell upon them the effect was charming.

Through the kindness of Mr. Silcock, I here give a plan of one half of the flower garden, the other half exactly corresponds with the one engraved. Our young friends will do well to draw it out on paper, and paint the beds the colour of the flowers. Down the centre is a broad gravel walk 18 feet wide. It occurred to me that the walk would be better away, and if water could be supplied, an ornamental fountain in the centre would add greatly to the effect. With regard to the planting of the beds, and the arrangement of the colours, there was a preponderance of Perilla nankinensis, Purple King Verbena, and Lobelia speciosa; but Mr. Silcock told me that many of the beds were destroyed by the late spring frosts causing vacancies, and there not being a sufficient supply of the same kinds of plants, the original design could not be adhered to.

In close proximity to the flower garden were some fine old Oaks, "kings of the wood," having evidently maintained their position for many years past. One I noticed of tremendous girth, three of us joined hands together and were unable to span round it within about three feet.

It would be a want of courtesy were I to close these notes without acknowledging Mr. Silcock's exceeding kindness, the profit I received, as well as the gratification, I felt on finding every part of this domain in such excellent keeping.—*QUINTIN READ, Biddulph.*

HOT-WATER PIPES PASSING THROUGH THE OPEN GROUND.

I HAVE had about 20 yards of two-inch pipes, flow and return, in the open ground, to heat a viney at some distance from the boiler. I have placed bricks below the pipes and also along the sides, and intend covering them over with semicircular tiles cemented on the brick to keep out wet, the whole to be covered over with puddle. Please say if you consider this fixture sufficient, and if it would be desirable to fill the chamber in which the pipes are with sawdust, so as to retain the heat for a longer time.—SAWDUST.

[We think your precautions sufficient, and if you left a small air opening in the culvert next the boiler, and the other end next the viney entirely open, we would do nothing more, as the heat and a constant charge of air would be carried from the culvert into the viney. If there are reasons why the end should not be left open into the viney, then you had better stuff the pipes round with sawdust.]

GRAPE-GROWING AT COOMBE ABBEY.

COOMBE Abbey is a new name in the lists of English gardens of note. A short time ago a public notice of this fine place appeared, in which some fine Barbarossa Grapes were spoken of. Having recently seen these Grapes, I can state that the notice referred to indicated but faintly the magnificent appearance of the Grapes, and the style of work that has grown up at Coombe Abbey within a few years.

A week ago I found ripe Strawberries being gathered, and was told that they were to be had in succession onwards. After seeing the ways and means to secure such a desideratum, the first doubts were considerably modified.

Had I seen nothing but the Barbarossa Grapes, it would have been quite satisfactory as to Mr. Miller's standing as a Grape-grower. In the same house are samples of that splendid Grape, the Lady Downes', equally fine with the Grapes I wish to speak of.

The Barbarossa at Coombe Abbey is growing on its own roots; the Vine has been planted about two and a half years. On one Vine are six bunches, the least not less than 5 lbs. Several of the bunches will weigh close upon 8 lbs. each, and these bunches are equal in shape and colour to the best Black Hamburgs. When seen in this style the Barbarossa has a very noble appearance. Lately, the Barbarossa has been spoken of as superior when grafted on the Hamburg. I have seen it in this way and it looks well, but appears to me something different from the Barbarossa. The leaves, when so grafted, are decidedly those of the Hamburg, shed early, and tell against the most valuable quality of Barbarossa, that of hanging long.

It is most gratifying to gardeners to see a young man of such enterprise as Mr. Miller, at the head of one of the most complete gardens in England.—CHAS. McDONALD.

WORK FOR THE WEEK.

KITCHEN GARDEN.

SHOULD frost prevail, every advantage must be taken of it to wheel manures and composts on to the various quarters requiring it, and if it cannot be trenched in at once, let it be laid in heaps at convenient distances and covered with soil. Ridged ground may be occasionally forked over and knocked about, to expose fresh surfaces to the action of the atmosphere. Collect as many leaves together as possible, they are invaluable for mixing with green manures for fermenting purposes, as they not only correct the rank and violent fermentation, but preserve a more steady and uniform heat for a greater length of time. Those of the Oak are much to be preferred, as they resist decomposition the longest; Beech comes next; after these there is little choice. Cauliflowers, surface-stirring among young growing crops of these and of Cabbage, Lettuce, &c., must be as diligently followed up now as in the summer, when vegetation is more rapid; indeed, there is no season when these important operations can be neglected with impunity. Frequent pulverisation of the soil acts as a great check to the penetration of frost in winter, and to the evaporation of

moisture in the summer. One indispensable condition is, that the ground must never be trodden on after the operation is completed. Celery, if very severe frost come on protect this, Parsley, and late Endive for spring use. Ground cropped in the preceding season with Carrots, Parsnips, or Potatoes, and found, as is frequently the case at this time, infested with grubs, should have a good dressing of soot or lime dug in, or if they cannot be had, the soil should be turned up in ridges for the winter.

FLOWER GARDEN.

At this season of the year a little labour will secure a valuable supply of material for enriching the flower-beds and borders. Leaves are everywhere at hand, they should be sedulously collected and stacked in some out-of-the-way place, with a mixture of road sand and light soil, rotten sticks, and decaying vegetable matter, and left to ferment; in a season or two the most valuable compost will be the result, especially suitable for many of the shrubs and plants which decorate our gardens, whose original position was probably near some primeval forest, the ever-accumulating leaves of which would naturally give a character to the surrounding soil, and encourage the growth of Rhododendrons, Azaleas, Magnolias, &c. Examine pillar and trellis Roses, and if the weather is favourable see if the soil wants renewing, or the kinds changing. If choice sorts, large holes capable of containing three or four barrowloads of well-prepared soil should be mads. Turfy loam of good quality is the chief thing, to this add a portion of rich rotten dung, and if at hand a little sandy peat or leaf mould. Have everything in the shape of protection ready for covering half-hardy plants on the approach of frost.

FRUIT GARDEN.

If any planting of young trees, or removing of others, has still to be done, attend to it at once. Let Gooseberry and Currant bushes be pruned on frosty mornings, or when the ground is in a dry state, so that it will bear treading upon without injury. After pruning give the ground among the Gooseberry and Currant trees a good dressing of lime or soot, which is useful as a preventive of their great enemy, the caterpillar. As Cherries, Gooseberries, and Currants have often their buds destroyed in severe weather by birds, take the opportunity of a damp day and well dust the shoots with a mixture of dry soot and quicklime using sufficient to cover the buds. Two or three dustings during the winter prevent in a great measure the ravages of these pests. Where the Raspberry grub is troublesome give a good dressing of gas lime before digging the ground, taking care to apply it regularly about the base of the plants.

STOVE.

A cautious application of fire heat must still be observed here. Keep the temperature rather low than otherwise for fear of exciting a premature growth. Cleanliness and a judicious use of the watering-pot should be strictly attended to. A small portion of air may be advantageously admitted on fine days, and will greatly assist in purifying the atmosphere of the house. Many things will be sinking into repose here, and from such water must be entirely withheld.

GREENHOUSE AND CONSERVATORY.

Remove Chrysanthemums as the flowers fade to make room for other things. The earliest started Camellias and Epacries will be advancing into bloom, as will the useful Erica hyemalis and Wilmoreana. A little fire heat will be indispensable here during cold damp foggy weather, in order to allow of admitting a little fresh air to carry off superfluous moisture without lowering the temperature too much; but this should be applied during the day, and all watering should be done in the morning, so that the atmosphere may be moderately dry before night, as a damp stagnant atmosphere is especially injurious to flowers. The winter flowers will now be making a splendid display in the conservatory, at least where they have received special attention through the summer to this end. The Euphorbia jacquiniæflora is one of the foremost of these beauties when properly cultivated. Poinsettia is a bold and dashing conservatory plant, and indispensable at this time of the year. Gesnera zebra, under high cultivation, is a most beautiful winter flower. Some of the genus Cytisus are very showy and fragrant, and as yellow flowers are somewhat scarce they become very useful.

FORCING-PIT.

This is a good time to introduce the following plants here, provided they have received the necessary treatment during the summer:—Rhododendrons, Azaleas, Persian Lilacs, Sweet Briars, Moss and other Roses, Ledums, Kalmias, Daphnes, Anne Boleyn Pinks, Dutch bulbs. Unless, however, they are in proper trim it will be labour in vain, and no mode of forcing or form of pit can compensate for this. The great secret of success, if the heat is wholly derived from fermenting materials, is to keep down accumulating damp and mouldiness by an almost constant ventilation. Those who are fortunate enough to possess pits heated by hot water will, of course, pursue a somewhat different course.

PITS AND FRAMES.

Look well to those structures containing stores for next summer, and have sufficient protecting materials always in readiness with which to cover them whenever the weather is unfavourable.—W. KEANE.

DOINGS OF THE LAST WEEK.

In all departments the work was chiefly a repetition of previous weeks. Looking after vegetables, protecting Strawberry-pots from excessive rains and slight frosts, clearing off faded leaves from the vineeries, &c.; potting Cinerarias and Primulas, and finding suitable positions for them.

The chief labour has been cleaning up, collecting tree leaves, sweeping and rolling lawn and walks, as most of the leaves are now fallen. This is a constant work, where neatness is an object, and fallen and drifting leaves always conjure up feelings of melancholy. Rough-pruned some strong Roses, &c., at the same time. All such work that was done before the late heavy rains on Wednesday, now looks nice, from the thorough washing the lawn and walks received.

Such washing of the latter, especially if salt is used in the summer for killing weeds, will help to make the walks all nice before the winter. We always feel reluctance to use salt for cleaning after April and May, as with fine gravel, if used later, there will be a tendency to softness in winter, which is disagreeable, especially in damp weather. When used early in spring, it will generally be completely washed out of the gravel before winter. When walks are too rough to be walked on comfortably, we mean from the gravel being large, and of an unbinding character, salt applied to kill weeds, will also ere long make the gravel fine enough. For fine gravel, even on this account, salt should always be used sparingly, as it will break the pebbles gradually down to dust. This wearing effect of salt should not be forgotten, and especially should it be remembered when used near the walls of a stone building. We have known cases where the salt after getting into the ground had risen through the stones, and moistened and mouldered them to a height of several feet. Salt, even for such purposes of cleaning, should therefore be used sparingly and with judgment. We once cleaned very easily some dirty, greasy, green pavement with salt and soda water, but it was a long time before we could get the salt out, so as to prevent it eating away the softer stones, and leaving a whitish dust on the surface, which told too clearly to the initiated the means that had been used for cleaning.

We rolled hard all the walks we could get at, as if there is the smallest fall to the sides—say 1½ inch from the centre to the sides of a nine-feet walk, a firm, smooth surface now, will send the rains off instead of allowing them to penetrate the walk; and when this is done, the walk being comparatively dry will be little influenced by frost, as it is unpleasant to go on walks when raised by such frosts, which they will certainly be if they have previously been wet. The firm rolling of walks early in winter is also an advantage in all shady places where moss and green is apt to accumulate in winter, as when a sharp frost comes the surface of the firm walk can be well scrubbed with an old hard broom, and almost the whole of the green thoroughly removed—a much easier and better process than digging and turning, which always leaves a walk uncomfortable for a time.

Notwithstanding the trouble of collecting and keeping

tree leaves, they are, perhaps, the most useful things to be found for a garden. With scarcely any trouble in the way of preparation, they furnish the means of themselves for slight hotbeds of all kinds. If collected damp, all that is necessary is to throw them into a heap, so that the somewhat violent heat may scatter slugs and kill a good many seed-weeds. When a stronger heat is required, as for Cucumbers, this will be secured by a mixture of horse dung, and then a casing of these sweet leaves will keep down all noxious steam. When collected when they are damp and wet it matters little where you put them, as unless in very small quantities they will be sure to heat; but if they can be procured dry it would be a good thing to store them in an open shed that is sparted all round but with a substantial roof to let off the wet. Here trodden rather firmly they will keep a long time and heat but little, and when wanted for use will always yield heat when sprinkled with water. We have known them thus kept as carefully as if they were Hops, and have seen them good even when two years gathered. It would be of little use thus housing them when collected wet as they would be sure to heat.

These leaves when decomposed may be used so continuously for manure until the ground, whether a flower-bed or a Cabbage-bed, may long for a change of enriching material; but this may always be helped by a slight application of lime, and though such leaf manure will not yield such heavy crops as a good dressing of farmyard manure, the produce will generally be much sweeter. Even Celery, a rampant feeder, we always think sweeter and crispier when grown chiefly in decomposed leaves.—R. F.

COVENT GARDEN MARKET.—DECEMBER 3.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

BUDDING ROSES ON THE BLACKBERRY (*An Inquirer*).—The Blackberry and the Rose are of the same natural order, but we never heard of their being united by budding, nor do we see any probable advantage that would arise from the Blackberry stock.

NECTARINES NOT RIPENING (*Hampshire Hills*).—Very rarely do Nectarines ripen well on an open wall however good the aspect. If you covered them with glass lights like those of a Cucumber-frame, the fruit would ripen and well repay you.

PLANTING PEACHES IN A GREENHOUSE (J. M.).—Your mode of planting will depend on what you want to use the house for. If chiefly for Peaches and preserving plants under them in winter, then by all means plant the trees in front of the bed, and train them right over all the roof on a trellis 16 inches from the glass. If you wish the bed to be used for placing plants in all times, whether fruiting plants or flowering ones, then by all means plant against the back of the bed and train to a perpendicular trellis along the pillars. You will have abundance of light for this trellis, provided no plants high enough to obstruct light are placed before it. The first plan would be the best for a regular Peach-house, the second would be best for giving light to a great variety of things in the same house. In either case the bed may be used for other purposes before the trees fill their allotted space. If the trees are planted at back, secure good drainage, or there may be too much soil there. Two feet will be ample, or even 22 inches.

PLANTING WATSONIAS, IXIAS, SPARAXIS, TRITONIAS, AND GLADIOLUS (J. F.).—The most suitable time to plant the first four is October, and for the Gladioli the latter part of March or beginning of April if the soil be light and well drained; but if cold and heavy, the end of April or beginning of May is a more fitting time. Directions for planting them will be found in our Number for October 25th, page 328, and we can add nothing to the information there given, save that the distance apart should be 4 inches, and that Watsonias require the treatment of Ixias. The ground in which Gladioli are to be planted should be dug deeply, and forked over once or twice during the winter if it be at all heavy, giving a liberal dressing of manure or leaf mould in the autumn, so that it may be thoroughly decomposed and incorporated with the soil by spring. Plant 9 inches apart, and cover with 3 or 4 inches of soil. These remarks relate to the Gandavensis section, and if yours be of the Rambosus section they should be planted in February or March.

RHODODENDRON STOCKS (S. C.).—The Rhododendron ponticum is a good stock, and the best we know. Any time will do to pot Rhododendrons, as they take up with such fine balls, but if there is one time better than another to pot them it is March. If you pot them now, or any time in mild weather from now until spring, they will be suitable for grafting at that season, but they are better established a year in pots, though this is not imperatively necessary if only the stocks are sufficiently strong. The Rhododendron is usually raised from layers, and we are not aware that it can be done successfully by cuttings. The Azalea cuttings two months struck would do better in a temperature of from 45° to 50°, than in one of 60°, which we presume is the minimum.

CAMELLIAS IN COCOA-NUT FIBRE REFUSE (L. S. M.).—The present state of the plants is probably due to your employing the dust in a fresh state, when it is much too open to be used for potting hardwooded plants; but if it was pressed firm and mixed with turf loam we do not see in what way it could bring on the consequences named. The plants were most probably neglected, as regards water, when placed on the top shelf of a stage in the greenhouse, and were not shaded from the sun. This is more likely to be the cause than potting in the refuse, for with us the Camellias have done well in it, but we reduced it to black or very dark mould. The circumstance of the leaves being blottedched confirms the above conclusions, as they are usually so when the young growths are made under an unshaded roof. The only remedy that we know of, will be to place the plants in a mild hoisted next April—say in one of tanner's bark in a viney, and to keep them there until new growths are made and the buds set, when they may be removed to a cooler and lighter structure. Camellias prefer a slight shade when making their growth, and a slight increase of heat and moisture. Tobacco smoke will assuredly kill thrips if you fill the house so that a plant cannot be seen, taking care to do so on calm evenings when the plants are dry, and employing the strongest shag tobacco. Smoke twice on alternate evenings, and afterwards whenever the insect appears. You will do little towards exterminating the pest if the plants are not kept cool, well aired, and supplied with moisture such as is needed. A sprinkling of water through a fine syringe on bright mornings is conducive to the health of Cinerarias and herbaceous Calceolarias.

SOIL FOR RHODODENDRONS (E. N. E.).—As your soil is very light and dry it will not grow Rhododendrons; but if it were dug out in the places where you propose planting to a depth of 1 foot 6 inches, and the holes filled with good turf peat soil, we have no doubt that you might grow Rhododendrons well. In putting the peat in the place of the soil taken out it should be chopped with a spade, so that it may not lie too lightly and open. In choosing the peat select the brown turfy sort; and if Bilberries grow in it prefer that to such as is found on the higher parts where the common Heath grows very dwarf and stunted.

SEAWEED FOR ASPARAGUS-BEDS (R. B.).—It is an excellent manure for Asparagus-beds. We applied a mulching of it quite fresh, when the stems of the plants were cut away in autumn, and left this covering on the surface until March. We then removed it, and having plenty of decayed seaweed we gave the beds a good coat of this, and just pointed it in with a fork.

WINDOW GARDENING FOR THE MANY (T. S.).—We cannot send a leaf without destroying a copy to do so.

THRIPS ON CAMELLIA LEAVES (Irish Lady).—There were traces of thrrips having been on all the leaves sent except one. Thrrips very rarely attack Camellias, this being only the second instance in our experience. Fill the house some calm evening with tobacco smoke so densely that a plant cannot be seen, and repeat the dose the next night but one. Syringe the plants on the underside of the leaves the day after each fumigation, taking care to have the foliage dry before fumigating again. It may be necessary to repeat the fumigation, for though tobacco smoke will destroy the insect it will not kill its eggs. Repeat the fumigation, therefore, if the pest appears. The atmosphere must have been kept as dry as that of the deserts of Arabia to render the Camellia leaves a suitable prey for thrrips. Keep the air more moist, otherwise the leaves will drop, and the flower-buds fall like a shower of hail.

STOVE BOILER (A Constant Subscriber).—We have reason to know, that the boiler named soon burns through, and that all the so-called boilers without setting do the same. There is little if any difference in them, and they all do their work pretty well, subject to the drawback of the outer casing speedily burning through. We cannot depart from our rule of not recommending one dealer in preference to another, and we have no doubt the one named will answer as well as others. If you will refer to the Number of this Journal for January 19th, page 58, you will find a notice of a boiler that would suit you. For further particulars our advertising columns will meet your wishes.

PROPAGATING VARIEGATED ELDER (M. F.).—You may take cuttings with three joints from the young growths, selecting those which are moderately strong, and cutting them transversely immediately below the lowest joint, and slantingly above the uppermost. Insert two joints in the soil, or if the cuttings have five joints three, leaving one in the former case, and in the latter case two out of the soil; the majority will root. Now is a good time to put them in. They grow best, however, from layers. A moderately light soil is best, and the cuttings may be put in in rows 1 foot apart, and from 3 to 6 inches asunder in the rows.

LILIES OF THE VALLEY NOT BLOOMING (H. A.).—You will benefit them much if you thin out one-half the plants or roots, so that they can obtain more air, planting those removed in soil well manured, and the plants not too close. They are best planted in rows 1 foot apart, and just covered with soil, giving a top-dressing of well-rotted manure or leaf mould an inch thick. There is no plant so much admired in its season as the Lily of the Valley, and yet it is the worst tended of all plants. They are crowded and huddled in some corner, and do not flower half so well as they would do if better cared for.

LIMNANTHES GRANDIFLORA SOWING (Mrs. F. W.).—There are two seasons of sowing this:—September for flowering in May and June, when it would be of most use to bees; and March and April for blooming in July, August, and September.

HEATING A SMALL PIT (An Amateur).—We are almost sure that as you have a boiler and hot-water pipes for your viney, the simplest and most economical mode for heating the small pit for Cucumbers, &c., at the end of the viney, would be to take a flow and return pipe to your pit, and from them heat the little pit independently of the viney. We would have been more decided on this point if you had given us the position of the boiler. Of course, the simplest of the portable hot-water apparatuses would do for such a little place; but we think the simplest and cheapest of them would cost you more labour and expense than heating from the present boiler. Were we to heat such a little place for ourselves, we would fix a brick Arnott's stove, with or without a flue in the house, but to be fed from the outside low enough to have a chamber for giving bottom heat and means for imparting moisture to the top heat.

CHARCOAL-HEATED STOVES—HOT-WATER APPARATUS—VENTILATING GREENHOUSE (A Subscriber).—We think the canaries will decidedly suffer unless there is a little ventilation at the top of the house night and day, or the laps of the glass admit fresh air. That the hot-water apparatus to be heated by lamps will be effectual for a house 21 feet by 12, will depend on the height of the house and the size of the lamps. For a house of that size, a little furnace would often be the best. There should also be funnel to take away the products of combustion from the lamps. If the water in your pipes is not more than 160° or 170°, you will require at least 50 or 60 feet of three-inch pipe. Where frost was merely to be excluded, we would prefer a small iron stove with a flat top for placing a basin of water on, with a pipe through the roof to take away the products of combustion. We object to the charcoal stove unless you have a funnel to take off the products of combustion. A stove, though small, if supplied with charcoal or broken coke, will give off a great amount of heat. The only care required is not to place the stove too near tender plants, and to neutralise the dry heat by moisture. Notwithstanding all improvements, the most economical plan for a single small house is a moveable stove, which may be taken out of the house from April to the end of October. Brick stoves are better than iron, but then they are fixtures. However, neatness is always gained when the fire either of a stove, or a furnace, or a boiler is fed outside of the house; but in a single house we believe it is gained at the expense of economy. Ventilation is not always wanted at the top of such a house, but it is desirable to be able to give it there when necessary. For a house only 21 feet long, however, you may dispense with the ugliness of ventilators in your fixed roof, by having a piece of the angular ends close to the apex made to open—say a right-angled triangle, with a base and perpendicular of 18 inches.

DESTROYING INSECTS IN HERBARIUM (W. R. H.).—The best way of doing this is to give the specimens a dressing with a solution of corrosive sublimate in methylated spirits of wine. It can be done with an ordinary painter's brush, and the sheets afterwards laid out to dry.

NAMES OF FRUITS (Tyro).—No. 1 (Apple), Sturmer Pippin; 2 (Pear), Striped Virgolette. (A. T.)—1, Cornish Gilliflower; 2, Marmalade Pippin; 3, Pigeon; 4, Autumn Pearnain. 1 (Pear), Benré Bosc. Grape Trebbiano.

NAMES OF PLANTS (G. S., Cornwall).—Teoma jasminoides, a native of New Holland. It requires a greenhouse in most parts of England, and its being in full bloom on November 28th, against the front of your house, is an evidence of the mildness of your situation. (*Conifera*).—The scraps of Scopolendrium it is impossible to identify. No. 8 may be digitatum starved. (C. C.).—Lastrea montana, synonymous with *L. oreopteris*. The other specimen apparently a starving of Ferdinandia eminens. (W. R. H.)—1, Eucus aculeatus; 2, Salix ambigua. (*Mary D.*)—Calceolaria scabiosafolia. (*Kentorian*)—1, Drynaria musaeifolia; 2, Gymnogramma chrysophylla; 3, Asplenium marinum; 4, Selaginella cuspidatum. (*Dr. Sandford*)—Your Queensland Cotton is the variety of *Gossypium barbadense*, known as "Sea Islands Cotton." (*Orchidophilus*)—Ornithogalum caudatum. The Saxifrage appears to be a tufted and much-cleft variety of *S. hypoleuca*. (C. R. B.)—1, Cyanotis vittata; 2, Coleus sp.? (bad specimen). (C. B. P.)—The Orchid is Epidendrum cochleatum. Gymnostachyus Verschaffeltii and Anthurium leuconeurum are totally distinct plants, wide as the poles apart. Send us a leaf and we will tell you which your plant is.

POULTRY, BEE, and HOUSEHOLD CHRONICLE

POULTRY JUDGES.

We have received an unsigned letter, but bearing a post-mark indicating whence it emanated, asking in no very courteous phrase "Whether we shrink from the sound opinion we formerly held that dealers should not be selected as judges." Our reply might be more brief than the query. We do not shrink from that opinion; but we have a few

remarks to add, from some of which we hope, in our turn, that our anonymous catechiser will not "shrink."

There is no doubt that among dealers in poultry are men possessed of much sounder knowledge of the good condition and desirable characteristics of each variety of fowl than can be found usually among amateurs; and the chief objection to dealers being judges is that they might recognise birds which they had sold, and might be prejudiced to decide in their favour. If, therefore, such amateurs as the Rev. Mr. Pulleine, the Rev. W. W. Wingfield, Mr. Hewitt, Mr. Andrews, and one or two more we might name, could officiate at all the poultry shows in the three kingdoms, we should not require any argument to induce us to say, Let them, and no others, be judges at those exhibitions. Those gentlemen, however, could not spare time to be such judges-general, and other amateurs so qualified are not sufficiently numerous. Dealers, and amateur-dealers, consequently have to be employed, and the distinction between these two classes is not always so clear, nor the characteristics of honesty always so developed in the amateur-dealer as to enable a committee to decide without hesitation to select him as judge. Letters written to judges indicating the pens in which certain birds were to appear; mending broken feathers, and removing other feathers that were of the wrong colour; having relations who were *bond fide* dealers, and with whose birds they were thoroughly conversant, are all events that have occurred among amateur-dealers, and which do not incline committees to select judges from among them.

This leads us to observe that we advise poultry show committees to trust to their own judgments in selecting the judges, for they have quite sufficient knowledge; and they stigmatise themselves if they act as if they thought they were not quite as honest—quite as little actuated by wrong motives—as are the members of any club, though these modestly assume that they ought to have the appointment of the judges and the entire management of all the poultry shows in the United Kingdom.

BIRMINGHAM POULTRY SHOW.

GREATNESS, according to our immortal poet, may be a birthright, or may be achieved, or it may be thrust on a man *nolens volens*, as with a friend of ours, who, in the machine-breaking riots, many years since, met some hundreds of rioters in a narrow lane, and, being on horseback, was at once surrounded, elected as leader, and compelled to go with them. The public-minded men who originated this great Exhibition, and who still carry it on, must, we think, belong to the second category. It is the most arduous, but it is also the most durable.

Sixteen great Shows, one after the other, all eclipsing their predecessors, are the results of those qualities that command success in life, whether they are exercised in a public, or a more limited private capacity. We can never look at this great undertaking without reverting to its beginning. We doubt whether the most sanguine of those who assisted at its birth anticipated a third of the success that has attended it. The show week has become an institution in Birmingham—cattle followed poultry, roots followed cattle, implements followed roots, and then, spite of size and galleries, Bingley Hall was full. The influence of the Exhibition is felt without—the Dog Show and the Flower and Fruit Shows are offshoots of it. Viewed as a public undertaking, it has filled the streets of Birmingham till police measures have become necessary to prevent crowds and accidents. Wherever you turn your eye you see a printed notice asking you to "keep to the right." This insures circulation spite of numbers. Beds are at a premium, and hotel accommodation can only be had by being bespoken long beforehand. The streets are filled with holiday people, and everything is done to make the town attractive. On Tuesday a novel procession was organised—fire engines, decked with flags and ribands, and carrying stalwart firemen, in smart uniforms and glittering helmets, were each drawn by four grey horses, and preceded by mounted police and a numerous band.

The increase of that part of the Show with which we have more particularly to do is a thing to be recorded annually. At different periods rules have been imperatively necessary

to limit the entries; and while, in many exhibitions, an extension of time is allowed, and exhibitors are solicited to send birds, in this instance there is no deviation from the fact; the entries close, and this year more than a hundred were refused, on the second day of November. The sum now given for poultry prizes is a very large one, and the managers are always open to suggestions for any alteration in the list. In poultry, as in other things, there are ebbs and flows, and the breed that one year is more numerous than any other, may in three years time be only third or fourth on the list. If exhibitors ask for fresh classes they are immediately given as an experiment. If they are well supported they are continued; if they are not they are withdrawn. Silver Grey Dorkings asked for classes, and had them, but they could not maintain them. The general Dorking classes had more prizes, and new ones were this year made for Crèves-Cœurs and Black Hamburgs. Both will apparently be successes.

We need hardly say that the *Dorking* classes were remarkable for the quality of the birds shown. They always are; but they were on this occasion worthy of notice from the fact there was not an inferior bird in them. The Viscountess Holmesdale and Capt. Hornby were the most distinguished; and we were glad to see that birds travelled from Dublin were able, in the face of such competition, to take a fourth prize. Mr. Palmer Williams accomplished this feat. There was hardly a pen in these classes that did not merit a commendation. The birds were large, handsome, and healthy.

The classes for hens and pullets were well filled, and showed excellent birds. Captain Hornby's pullets will make good hens next year. Dublin again took the second prize with fine birds of Mr. Boyle's. Lady Holmesdale and the Rev. Mr. Cadogan were deservedly prizetakers.

The White Dorkings were highly meritorious.

We have before spoken of ebbs and flows, and an instance of them is now before us. A few years since *Spanish* fowls were supposed to be at their highest, and they then declined in importance and merit. They have scarcely held their ground these four years. The classes now shown indicated one of the most extraordinary improvements ever seen; there were lots of perfect birds. Mr. Rake's, shown by their different purchasers, were the most successful. Mr. Jones, Mr. Lane, Lady Holmesdale, Miss Biggar, and Mr. Teebay, not only sent capital birds, but they were all in unusually good condition. We know not the reason, but at all shows the classes for Spanish hens and pullets fill badly as to numbers. The present was no exception.

Cochin-Chinas were good as were ever shown during the sixteen years that have passed since they first tenanted Bingley Hall. Captain Heaton's strain proved itself the best last year, and it kept its word of promise now. His yard was first in adults, chickens, and single cocks. But it must not be thought the success was easy. Neither Mr. Stretch nor Mr. Bates is defeated without a struggle in these classes; and Mr. Bishop showed himself strong in numbers as well as quality. In these classes the hens and pullets are far more numerously sent than in most others; Messrs. Smith and Yardley were deservedly winners. The Brown and Partridge were very good, and they introduced some new names among the winners. An old one, Mr. Stretch, was first in chickens. The Whites were excellent; Mr. Chase and the Rev. F. Taylor took all the prizes. These formed numerous classes. We believe some of the heaviest Cochins ever seen might have been found among the Grouse and Partridge birds.

The next class is one that has steadily and deservedly worked its way in the public estimation. *Brahma Pootras* have held on through abuse and neglect till they have become an important class. Two of the five prizes went to Dublin, and the first in adults was awarded to Mrs. Har-greaves, of Arborfield.

The *Malays* were excellent, but it is a pity they are not more numerous. The same may be said of the *Crèves-Cœurs*.

The *Black Hamburgs* justified the liberality that gave them classes by numerous entries, and their exhibitors show they can send first-rate specimens in good condition. We are told these beautiful birds are common in parts of Yorkshire. We look for large classes in future, and therefore offer a word of advice. These birds must not have white faces. The Golden-pencilled were far better than the

Silver. The Silver breeders are neglecting the accuracy of the markings, and forgetting the tendency there is in these birds to become lighter as they become older. Clear hackles have been secured at the cost of pencilling on the wing and tail. We think perfection in these birds must not be sought. If a well-pencilled tail and marked wing can only be had in conjunction with a partially-spotted hackle, we must submit to it as the less evil. Although the same may be said of the Spangled classes, it must be qualified. The Silvers were only inferior to the Golden because the latter were unusually good. We have seldom seen a better pen than that shown by Mr. Hyde. All the prize birds in these classes were good, but the Silvers were in some instances too light. The cocks were especially deficient in marking on the wings.

We can speak most highly of all the *Poland*; the only desideratum was an increased number of entries. Mr. Adkins has a speciality for Silvers, and Mr. Edwards for Black with white tops. All were beautiful.

The Various class brought many pens of Cuckoos, a beautiful pen of La Flèche, some good Siskies, but none of the monstrosities that used to fill up its numbers in former years.

As usual, the Game formed a capital show without assistance from any other breed. Their condition and beauty of feather were worthy of all praise, and showed that the descendants of the old cockers had not failed to benefit by the knowledge and experience of their predecessors. It is almost impossible to particularise all that deserve especial notice; yet the veriest tyro in Game fowls, or one who had never before admired them, would not fail to be struck with the surpassing beauty and excellence of Mr. Statter's cock that took first in Class 50, and deservedly received the extra prize of five guineas as the best in the Show. Mr. Worrall's pullets, and two pens belonging to Sir St. G. Gore, were next in merit.

It is almost painful to leave as many good birds unnoticed as we are compelled to do in these beautiful classes. Our last week's hasty prize list will have told the winners. The Brown Reds were certainly this year better than the Blacks. The Duckwings were very handsome; Mrs. Hay, Messrs. Wood, Aykroyd, and Fletcher may be proud of their laurels.

Our task is something like Penelope's web. We have to begin again. We have no doubt—indeed we are sure—the Single Cock classes are a boon to purchasers. We doubt whether they are as acceptable to judges, and we are sure they are not to reporters.

It may be said of the Dorkings that they presented an unrivalled show. Lady Holmesdale, Lady S. Des Vœux, and Messrs. Tudman, Robinson, and Arkwright were successful—no small boast. A prohibitory price hardly saved the birds in this class, and all moderately-estimated ones were immediately sold.

The Spanish showed the same improvement that the general classes did. Right good birds were sent from all parts of the United Kingdom. In sporting phraseology we should still say—Bristol for choice. Manchester bore the bell for Cochin-China cocks—Capt. Heaton first, closely followed by many of the “celebrities.” In Partridge cocks, there was a notable display of excellent birds, many of great weight. Brahma Pootra cocks richly deserved the prizes awarded to them. Messrs. Pigeon, Statter, and Boyle showed very fine birds, and took the prizes in order.

The Hamburgs call for little notice beyond a general commendation, and the remark that in these classes the best cocks seemed to be reserved to compete together rather than to exhibit themselves with their hens. In these, as in the Dorkings, the non-prohibited birds were snapped up. The Polish cocks were good. Spite of Shakespeare's ideas on the subject, there must be something in a name. The same occur in the Game cock classes as in the general competitions; and Mr. Statter also takes the extra silver cup for the best among the good. Mr. Matthew Leno and Mr. Uriah Spary took the prizes for Gold and Silver-laced Bantams. A cock among the latter must be as tired of taking prizes as Talleyrand was of oaths of allegiance. The Black and White were very numerous and beautiful; and among the Varieties, which mustered well, there were all sorts of oddities—the Japanese, which appear ashamed of their legs, and hide them with their wings; the booted White ones; the Speckled ones; three hens of serious-looking, most diminutive Buff Cochins; and many whose

origin we can only guess at. And then, the Game Bantams—such a display of little beauties—Black-breasted Reds, Brown Reds, Duckwings, and Piles; Miss E. Crawford took first and extra prize. There were scarcely any inferior pens. Mr. Postans's first-prize birds were beautiful.

The public who read this, if any get as far, has no idea of the difficulty in finding words to describe the same events eighty-three times over without falling into the most painful tautology. We are arrived at Class 83—Aylesbury Ducks. We may expect to go on swimmingly. Mrs. Seamons achieved an exploit—first prize with three Ducks weighing 27 lbs.; Fowler second, 25 lbs.; Seamons third, 24 lbs. This was a good class, but it was a nonentity compared with its successor, Rouen Ducks. There were halcyon days when three out of four pens had faulty bills, and half the remainder were fitted to ride feather weight. Now all want close examination, and half require to be weighed. Fifty pens competed—Mr. Shaw first, 25 lbs.; Mr. Worrall second, 24½ lbs.; Mr. Anderson third, 24 lbs.; Capt. Hornby fourth, 23½ lbs. Many commended pens deserved prizes. Beunos Ayrean were remarkably good, especially the three prize pens; nine others were in the prize sheet. Various Ducks brought Carolinas, Brown and White Calls, of great merit.

Getting to the Geese is like seeing the lights in the distance; we are getting near home. Mr. Duxbury's old White Geese weighed 84 lbs.; Mr. Kershaw's, 57 lbs.; and Mr. Faulkner's, 54 lbs. The young ones, Mrs. Seamons', 57 lbs.; Mr. Lysett's, 52 lbs. The old Grey birds weighed badly. The young ones made amends—Mrs. Seamons', 61 lbs.; Mr. Lort's, 57 lbs.

The old prize Turkeys, 63 lbs., 61 lbs., and 60½ lbs.; the young birds, 47 lbs., 46½ lbs., and 46 lbs. Several of the commended pens weighed more than 43 lbs.

It is needless to say everything was well conducted; Messrs. Luckcock, Matthews, Shackel, Wright, Lowe, Mapplebeck, Adkins, Sabin, and others are always at their posts. No question can arise that will not have an immediate solution; no complaint that will not meet with ready redress. In the name of the poultry public we thank them all, and congratulate them on their deserved and continued success.

The heavy rain on Monday morning did not diminish the attendance of visitors to the extent which might have been expected. The number was 7083, against 6445 last year—namely, 4,248 by subscribers' tickets; 2,131 by payment of 5s.; and 704 by payment of 1s. each.

In the poultry sales, up to Tuesday evening, there had been a slight falling off, the amount on Monday being £616 7s. 6d., against £661 12s. 6d. last year; and on Tuesday £208 19s., against £189 7s. in 1863.

We published the prize list last week, and now give the commendations.

DORKINGS (Coloured).—Highly Commended, A. Potts, Hoole Hall, Chester; J. D. Hewson, M.D., Coton Hill, Stafford; H. Lingwood, Needham Market, Suffolk. Commended, Rt. Hon. Countess of Dartmouth, Patshull, Albroton, Wolverhampton; Lt. Hon. Lady Bagot, Blithfield Hall, Rugeley; A. Stanford, Eatons Ashurst, near Steyning, Sussex; Miss Wilcox, Nailsea Court, near Bristol. **Chickens.**—Highly Commended, Rt. Hon. Viscountess Holmesdale, Linton Park, Kent; Lady Bagot; Sir J. D. Wauchope, Bart., Miller's Hill, Dalkeith, N.B.; Rev. J. F. Newton, Kirby-in-Cleveland, near Stokesley, Yorkshire; H. Lingwood; J. Anderson, Meigle, Forfarshire; J. White, Warlaby, Northallerton; A. Potts; R. W. Boyle, Dundrum, Dublin. Commended, Mrs. Arkwright, Etwall Hall, Derby; A. Potts; J. Frost, Parham, Suffolk; Lord Stanhope, Bentley Hall, Burton-upon-Trent. **DORKING HENS.**—Highly Commended, Mrs. Young, Eatington Vicarage, Stamford-upon-Avon; Rev. J. F. Newton, Kirby-in-Cleveland, Yorkshire; Rev. E. Cadogan, Walton Parsonage, Warwick; Sir St. G. Gore, Bart., Hopton Hall, near Wirksworth, Derbyshire; W. Harvey, Sheffield; J. D. Hewson, M.D., Coton Hill, Stafford.

DORKING PULLETS.—Highly Commended, Miss Wilcox, Nailsea Court, near Bristol; W. W. Bartlam, Henley-in-Arden. Commended, Rev. E. Cadogan, Walton Parsonage, Warwick; T. Whittington, Preston Hill, near Henley-in-Arden; J. R. Smith, Edgbaston.

DORKINGS (White).—**Chickens.**—Highly Commended, J. Clift, Dorking, Commended, J. Robinson, Garstang.

SPANISH.—Commended, J. L. Lowndes, Aylesbury; R. B. Postans, Brentwood, Essex. **Chickens.**—Highly Commended, J. Shorthose, Newcastle-on-Tyne. Commended, W. R. Bull, Newport Pagnell, Bucks; R. Teebay, Fulwood, near Preston; E. Draper, Northampton; A. Heath, Calne, Wilts; E. Jones, Clifton, Bristol; R. B. Postans.

SPANISH HENS.—Highly Commended, R. Teebay, Fulwood, near Preston. Commended, J. Smith, Walsall.

SPANISH PULLETS.—Highly Commended, Miss Biggar, Ecclefechan, Dumfriesshire; E. Jones, Clifton, Bristol.

COCHIN-CHINA (Cinnamon and Buff).—Highly Commended, T. Stretch, Ormskirk. Commended, C. T. Bishop, Lenton, near Nottingham. **Chickens.**—Highly Commended, T. Boucher, Birmingham; H. Bates, Yardley, near Birmingham. Commended, C. T. Bishop; H. Bates; Mrs. R. White, Sheffield; T. Stretch; J. Nelson, Heaton Mersey, Manchester.

COCHIN-CHINA HENS (Cinnamon and Buff).—Highly Commended, J. G.

Sugden, Keighley, Yorkshire; J. Stephens, Walsall; R. Adams, Handsworth. Commended, H. Bates, Yardley, near Birmingham.

COCHIN-CHINA PULLERS (Cinnamon and Buff).—Highly Commended, J. K. Fowler, Aylesbury; Capt. Heaton, Manchester; H. Yardley, Birmingham; T. Boucher, Birmingham; W. Wood, Sheffield; J. F. Fountain, Derby. Commended, R. Boddington, Birmingham; T. Stretch, Ormskirk.

COCHIN-CHINA (Brown and Partridge-feathered).—*Chickens*.—Highly Commended, E. Tudman, Whitchurch, Salop; — Cartwright, Oswestry; J. K. Fowler, Aylesbury. Commended, J. Foole, Ulverston, Lancashire.

COCHIN-CHINA HENS (Brown and Partridge-feathered).—Highly Commended, R. Adams, Handsworth, Birmingham.

COCHIN-CHINA PULLETS (Brown and Partridge-feathered).—Highly Commended, E. T. Holden, Walsall. Commended, C. Kershaw, Ashton-under-Lyne; E. Tudman, Whitchurch, Salop.

COCHIN-CHINA (White).—Highly Commended, W. Dawson, Hopton, Mirfield, Yorkshire; R. Chase, Balsall Heath, Birmingham; H. Yardley, Birmingham; G. Lamb, Compton, near Wolverhampton. *Chickens*.—Highly Commended, Rev. F. Taylor, Kirby Lonsdale; G. Lamb; H. C. Woodcock, Rearsby, near Leicester; F. E. Zurhorst, Dublin; W. Dawson. Commended, G. Lamb; F. W. Zurhorst; R. Chase, jun.

BRAHMA POOTRA.—Highly Commended, T. Pomfret, Hopton Lane, near Preston; R. W. Boyle, Dundrum, Dublin; F. Sabin, Birmingham. *Chickens*.—Highly Commended, J. Poole, Ulverston, Lancashire; F. R. Pease, Darlington. Commended, J. K. Fowler, Aylesbury; T. Pomfret.

MALAY.—Highly Commended, J. J. Fox, Devizes; W. Watson, Calstock, Tavistock. *Chickens*.—Highly Commended, Rev. A. G. Brooke, Ruyton XI. Towns, Salop.

CREVE-CŒUR.—*Chickens*.—Highly Commended, J. Harrison, Blackpool; W. Blinkhorn, jun., St. Helens, Lancashire.

BLACK HAMBURGH.—*Chickens*.—Highly Commended, W. W. Nicholls, Sale, near Manchester. Commended, C. Sedgwick, Keighley, Yorkshire; W. K. Duxbury, Leeds.

HAMBURGH (Golden-pencilled).—Commended, H. Beldon, Gilstead. *Chickens*.—Highly Commended, Messrs. J. & F. Howard, Bedford; C. Tat-tersall, Waterfoot, near Manchester; N. Marlow, Denton, near Manchester. Commended, Rev. R. Roy, Worcester.

HAMBURGH (Silver-pencilled).—*Chickens*.—Highly Commended, Rt. Hon. Viscountess Homedale, Linton Park, Kent.

HAMBURGH HENS (Pencilled).—Commended, H. Beldon, Gilstead; Rev. T. L. Fellowes, Acle, Norfolk.

HAMBURGH PULLETS (Pencilled).—Highly Commended, F. Pittis, jun., Isle of Wight (Golden); E. Smith, Middleton, near Manchester (Golden). Commended, Rev. R. Roy, Worcester (Silver); A. C. P. Gurney, Hampton Place, near Hereford (Golden).

HAMBURGH (Golden-spangled).—Commended, W. Kershaw, Heywood, near Manchester. *Chickens*.—Commended, C. Sedgwick, Keighley, Yorkshire; C. Broadbent, Saddleworth, Yorkshire; J. G. Sugden, Keighley, Yorkshire.

HAMBURGH (Silver-spangled).—Highly Commended, H. Beldon, Gilstead. *Chickens*.—Highly Commended, Viscountess Homedale; G. E. Hardman, Rawtenstall, Manchester; T. Burns, Leigh, near Manchester; E. Collinge, Middleton, near Manchester. Commended, Mrs. H. Sharp, Bradford; J. Fielding, Newchurch, near Manchester.

HAMBURGH HENS (Spangled).—Highly Commended, H. Beldon, Gilstead; S. H. Hyde, Ashton-under-Lyne. Commended, H. Carter, Holmfirth; Messrs. Aston & Sons, Birmingham.

HAMBURGH PULLETS (Spangled).—Highly Commended, Sir St. G. Gore, Bart., Wirksworth, Derbyshire; E. Collinge, Middleton, near Manchester. Commended, W. Kershaw, Heywood, near Manchester.

POLISH FOWL (Black with White Crests).—*Chickens*.—Commended, T. P. Edwards, Lyndhurst, Hants; J. Sunderland, Coley Hall, near Halifax.

ANY OTHER DISTINCT VARIETY.—Highly Commended, H. Savile, Ollerton, Notts (Japanese Silky); J. L. Lowndes, Aylesbury (Andalusians).

GAME FOWL (Black-breasted Reds).—*Chickens*.—Highly Commended, M. Billing, jun., Erdington, near Birmingham; J. H. Williams, Welshpool. Commended, J. Fletcher, Stoneclough, near Manchester; J. Anderson, Meigle, Forfarshire; E. C. Gilbert, Penkridge, Staffordshire; W. Whitehouse, Henley-in-Arden; J. Smith, Grantham; M. Billing, jun.

GAME FOWLS (Brown and other Reds, except Black-breasted).—Highly Commended, J. Fletcher, Stoneclough, near Manchester. Commended, J. Linnell, Coventry; M. Billing, jun., Erdington, near Birmingham; T. Statter, Manchester; E. Aykroyd, Bradford. *Chickens*.—Highly Commended, Sir St. G. Gore, Bart., Wirksworth; M. Billing, jun.; G. E. Meredith, Wellington, Salop; A. B. Dyas, Madeley, Shropshire. Commended, J. Fletcher; T. Statter.

GAME HENS (Black-breasted and other Reds).—Highly Commended, W. Boyes, Beverley, Yorkshire.

GAME PULLETS (Black-breasted and other Reds).—Highly Commended, Capt. Heaton, Manchester; J. H. Williams, Welshpool; M. Billing, jun., Erdington, near Birmingham; J. Halsall, Ince, near Wigan; J. H. Braikenridge, Chew Magna, near Bristol. Commended, J. Wood, Wigan; J. Smith, Grantham; R. Swift, Southwell, Nottinghamshire.

GAME PULLETS (Except Black-breasted and other Reds).—Highly Commended, E. Lowe, Comberford Mill, near Tamworth.

SINGLE COCKS.

DORKING.—Highly Commended, Sir J. D. Wauchope, Bart., Miller's Hill, Dalkeith, N.B.; W. Endall, Henley-in-Arden; W. H. Denison, Woburn, Bedfordshire; J. K. Fowler, Aylesbury; R. B. Postans, Brentwood, Essex; E. Shaw, Oswestry; Rev. J. G. A. Baker, Old Warden, Bedfordshire. Commended, J. White, Warlaby, Northallerton; J. Drewry, Newton Mount, Burton-upon-Trent; Rev. E. Cadogan, Walton Parsonage, Warwick; W. W. Barlam, Henley-in-Arden; A. Stanford, Eatons Ashurst, near Steyning, Sussex.

SPANISH.—Highly Commended, Viscountess Holmesdale; G. Robson, Hull; W. R. Bull, Newport Pagnell, Bucks; J. L. Lowndes, Aylesbury; D. Parsley, Bristol; R. Teebay, Fulwood, near Preston; H. Lane, Bristol; R. Paton, Kilmarnock; E. T. Holden, Walsall. Commended, R. Paton.

COCHIN-CHINA (Cinnamon and Buff).—Highly Commended, Mrs. R. White, Broomhall Park, Sheffield; W. Dawson, Hopton, Mirfield, Yorkshire; W. Wood, Sheffield; T. Stretch, Ormskirk. Commended, C. T. Bishop, Lenton, near Nottingham; F. W. Zurhorst, Donnybrook, Dublin; Capt. Heaton, Manchester.

COCHIN-CHINA (Except Cinnamon and Buff).—Highly Commended, T. Stretch, Ormskirk; R. White, Broomhall Park, Sheffield; W. P. Merry,

Coventry. Commended, T. Stretch, Ormskirk; F. W. Zurhorst, Donnybrook, Dublin.

BRAHMA POOTRA.—Highly Commended, H. Savile, Ollerton, Notts; H. James, Walsall; W. L. Barclay, Knott's Green, Leyton, London, N.E. Commended, Mrs. Hurt, Alderwasley, Belper.

HAMBURGH (Golden-pencilled).—Highly Commended, J. Garr, Wibsey Slack Side, near Bradford; C. Tat-tersall, Waterfoot, near Manchester. Commended, W. H. Dyson, Horton Bank Top, near Bradford; J. Holland, Worcest.

HAMBURGH (Silver-pencilled).—Highly Commended, J. G. Sugden, Eastwood House, near Keighley, Yorkshire. Commended, D. Harding, Middlewich, Cheshire; J. Robinson, Garstang; J. Holland, Worcester.

HAMBURGH (Golden-spangled).—Highly Commended, Messrs. Aston and Sons, Birmingham; I. Davies, Harborne, near Birmingham; J. Roe, Hadfield, near Manchester. Commended, H. E. Emberlin, Humberstone, Leicestershire.

HAMBURGH (Silver-spangled).—Highly Commended, Viscountess Holmesdale, Linton Park.

GAME (Black-breasted Reds).—Highly Commended, J. Stubbs, Weston Hall, Stafford.

GAME (Brown and other Reds, except Black-breasted).—Highly Commended, J. Linnell, Anstey Hall, Coventry; R. Swift, Southwell, Notts.

BANTAMS (Gold-laced).—Highly Commended, Rev. G. S. Cruwys, Tiverton, Devon; J. Crossland, jun., Wakefield; M. Leno, jun., Dunstable, Bedfordshire.

BANTAMS (Silver-laced).—Highly Commended, U. Spary, Dunstable, Bedfordshire. Commended, F. R. Pease, Southend, Darlington.

BANTAMS (White, Clean-legged).—Highly Commended, Sir St. G. Gore, Bart., Wirksworth, Derbyshire; Capt. Wetherall, Loddington, near Kettering; G. Hellowell, Walkley, near Sheffield; H. E. Emberlin, Humberstone, Leicester.

BANTAMS (Black, Clean-legged).—Highly Commended, F. Pittis, jun., Newport, Isle of Wight. Commended, J. Ludlow, Solihull; F. Pittis, jun.; J. Jackson, Hall Green Hall, near Birmingham.

BANTAMS (Any other variety except Game).—Highly Commended, R. Chase, jun., Balsall Heath, Birmingham; H. C. Woodcock, Rearsby, near Leicester; J. D. Newsome, Batley, near Leeds; F. R. Pease, Southend, Darlington; A. G. Cane, St. John's College, Cambridge.

GAME BANTAMS (Black-breasted and other Reds).—Highly Commended, R. Hawksley, jun., Southwell, Notts; J. Munn, Newchurch, near Manchester; J. W. Morris, Rochdale; C. Aukland, Chesterfield; R. B. Postans, Brentwood, Essex; Rev. G. Raynor, Kelvedon Hatch Rectory, near Brentwood, Essex.

GAME BANTAMS (Any other variety).—Highly Commended, J. Crossland, jun., Wakefield; J. G. Pearson, Whitchurch, Salop.

GAME BANTAM COCKS.—Highly Commended, Miss S. N. Hill, Shrewsbury; Mrs. C. W. Brierley, Middleton, near Manchester; J. D. Newsome, Batley, near Leeds; J. Holme, Knowsley, near Prescot; J. W. Morris, Rochdale; H. C. Woodcock, Rearsby, near Leicester; W. J. Cope, Barnsley; E. Brown, Sheffield.

DUCKS (White Aylesbury).—Highly Commended, T. Hollis, Reading; Mrs. Seemons, Aylesbury; J. K. Fowler, Aylesbury.

DUCKS (Rouen).—Highly Commended, T. Statter, Manchester; J. Holme, Knowsley, near Prescot; J. Munn, Newchurch, near Manchester; H. C. Woodcock, Rearsby, near Leicester; H. Worrall, West Derby, near Liverpool; W. H. Denison, Woburn, Bedfordshire. Commended, T. Hollis, Reading; S. Lang, jun., Redland, Bristol.

DUCKS (Black East Indian).—Highly Commended, Miss Clifton, Whitton, Worcester; J. W. Smith, Oundle, Northamptonshire; Mrs. Wolferstan, Tamworth; J. Holdaway, Weston, near Bath. Commended, Mrs. Wolferstan; F. W. Earle, Edenhurst, Prescot; Rev. W. Gover, Saltley Training College, Birmingham; W. Watson, Calstock, Tavistock; J. K. Fowler, Aylesbury.

DUCKS (Any other variety).—Highly Commended, D. Parsons, Cuerdon, near Preston. Commended, H. Savile, Ollerton, Nottinghamshire.

GEES (White).—Highly Commended, H. Savile, Ollerton, Notts. Commended, J. K. Fowler, Aylesbury; W. Lort, jun., King's Norton, near Birmingham.

GEES (Grey and Mottled).—Highly Commended, E. Herbert, Powick, near Worcester; Hon. Mrs. Colville, Lullington, Burton-upon-Trent; J. K. Fowler, Aylesbury.

TURKEYS.—Highly Commended, Mrs. A. Guy, Eaton, near Grantham; W. Lort, jun., King's Norton, near Birmingham. **Poults**.—Highly Commended, Mrs. Wolferstan, Tamworth; Mrs. A. Guy, Eaton, Grantham; J. Smith, Breeder Hills, Grantham.

PIGEONS.

The Pigeons, numbering three hundred pens, were ranged in one of the galleries, and were of easy access to the visitors.

Almond *Tumblers* formed the first class. Mr. Else was first with a pair very fine in feather; the second-prize pen contained a splashed and unevenly-matched pair; while Mr. Eden's third-prize birds, although not equal in feather to the first, were very much superior in head and beak to either pen.

Carriers were divided into four classes of single birds. In the two for Blacks, cocks and hens respectively, Mr. Else took both first prizes; Mr. Eden had second positions, each with particularly good birds. In cocks, Any other colour, Mr. Eden had first with a splendid Dun; Messrs. Siddons second with a good bird of the same colour. In the like class for hens the first prize went to a Dun cock, shown by mistake we imagine.

In the four classes for *Powters* Mr. G. R. Potts had a great success, taking three out of the four first prizes. In that for Red or Blue cocks a Red, very lengthy in feather and limb, was first, and a good Blue second. In Powter cocks,

Any other colour, both prizes were awarded to good Whites, Mr. Eden's first-prize birds being particularly noticeable. In Powter hens, Red or Blue, Messrs. Potts and Eden took the prizes with fine Blues, and the former received high commendation for a very handsome Red. In Powter hens, Any other colour, a very fine Black was first, White second, and a fair Yellow was highly commended.

The class for *Balds* was only small. Mr. Ridpath substituted a fine pair of Blues for his Sunderland Blacks, and took first position; Mr. Esquillant had second with very good Blues, the first-prize Islington Yellows being unnoticed.

In *Beards* Mr. Oates maintained his position with his splendid Blues, Mr. Else taking second.

In Mottled *Tumblers* Mr. Eden's wonderful Black Mottles out-distanced competition. In *Tumblers*, Any other variety, good Kites took both prizes.

The class for *Runts* was unusually large and good. The first and second prizes were awarded to Blues, the third to Silvers.

In *Yellow Jacobins* Mr. J. T. Lawrence held his own, gaining both prizes with splendid birds; and in *Jacobins*, Any other colour, Blacks took both prizes. Mr. Lawrence's first-prize pen contained a hen rather coarse in head; the second-prize pair were rather faulty in eye, but small and fine. Mr. Esquillant's extraordinarily fine pair of Cup Reds were entirely passed over.

In *White Fantails* plain-headed birds won on this occasion (both prizes falling to crested birds last year); a crested pair received high commendation, and an unusually good pair of plain-headed were commended. *Fantails*, Any other colour, only numbered four pens, the prizes being awarded to good Blues and Blacks in the order named.

In *Mottled Trumpeters* Mr. Shaw held his accustomed place, taking first. The cock has occupied the same position at Birmingham five years in succession, being the remarkable old bird originally belonging to Mr. F. Mewburn. Although well shown, the hen accompanying him is not equal to his former companion for four years. Mr. Robinson had second prize with a pen much out of condition, and containing one of his Sunderland Cup birds. In *Any other colour Trumpeters* Mr. Shaw had first with good Black, peculiarly known as "Balaklavas," and Mr. Oates was second with capital Whites.

In the two classes for *Owls* the small foreign variety took all the prizes. In that for Blue or Silver the former gained both prizes. A very poor pair of light powder Blues were highly commended. In *Owls*, Any other colour, Mr. Sanday repeated his Sunderland victory with his well-known Whites. Whites were also second and highly commended; a pair of Blacks, unevenly matched in eyes, also received the same distinction.

In *Nuns* good black-headed birds took the prize.

Turbits were divided into two classes. In the one for Red or Blue, Red had both prizes, the first being given to a peaked-crowned pair, and the second to very good shell-crowned birds. In *Turbits*, Any other colour, a strong coarse pair of peak-crowned Yellows were first, and Silvers second, Blacks being commended. At Birmingham last year shell-crowned birds took precedence in both classes.

Barbs also had two classes, Blacks and Any other colour, with seven pens competing in both classes. Mr. Eden obtained first in each with Blacks and Yellows respectively. In the latter class Mr. Oates's second-prize pen contained a particularly good Red cock, much the best bird exhibited.

Dragoons formed a large class. Blues were first, Silvers second, and Yellows third.

Magpies, *Antwerps*, and *Archangels* were ordinary classes.

In Any other new or distinct variety, Mr. Shaw's German Letz were first, Mr. Yardley's Satinettes second, and Mr. Heath's Isabels third. *Frillbacks* and *Black Spots* were highly commended; while *Blue Brunswick*s and *Rangoon Shakers* received commendation.

The Commendations were as follow:—

TUMBLERS (Almond).—Highly Commended, J. Ford, Monkwell Street, London.

CARRIER (Black).—Cock.—Highly Commended, T. Colley, Sheffield. Commanded, E. Snow, jun., Birmingham; T. Colley.

CARRIER (Any other colour).—Cock.—Commended, C. J. Samuels, Longsight, near Manchester. Hen.—Highly Commended, T. Colley, Sheffield. Commanded, G. Robson, Hull; J. W. Edge, Aston New Town, Birmingham.

Powter (Red or Blue).—Cock.—Very Highly Commended, R. Adams, Handsworth, Birmingham. Hen.—Highly Commended, G. R. Potts, Sunderland. Commanded, G. H. Ellis, Leicester.

Powter (Any other colour).—Cock.—Highly Commended, J. R. Harvey, M.D. M.D., Cork. Hen.—Highly Commended, J. R. Harvey, M.D.

BEARDS.—Highly Commended, J. Percival, Rye Lane, Peckham. Commanded, J. Fielding, jun., Rochdale.

TUMBLERS (Mottled).—Commended, F. Else, Bayswater, London.

TUMBLERS (Any other colour).—Commended, S. Shaw, Halifax.

RUNTS.—Highly Commended, C. Baker, Pheasantry, Chelsea; T. D. Green, Saffron Walden, Essex. Commanded, T. D. Green. A good class.

FANTAILS (White).—Highly Commended, H. Yardley, Birmingham.

Commanded, F. Else, Bayswater, London. A very good class.

TRUMPETERS (Mottled).—Commended, S. A. Taylor, Birmingham.

OWLS (Blue or Silver).—Highly Commended, C. F. Allison, Acton, Middlesex; C. Bulpin, Bridgewater. Commanded, F. Else, Bayswater.

TURBITS (Any other Colour).—Commended, R. Adams, Handsworth, Birmingham.

DRAGONS.—Highly Commended, T. Whitley, jun., Halifax. A good class.

MAGPIES.—Highly Commended, P. Eden, Salford. Commanded, E. Pigeon, Lympstone, near Exeter.

ANTWERS.—Highly Commended, H. Yardley, Birmingham.

TURBITS (Red or Blue).—Commended, H. Yardley, Birmingham.

ANY OTHER NEW OR DISTINCT VARIETY.—Highly Commended, H. Yardley, Birmingham (Spots); F. H. Paget, Birrall, Leicestershire (Rangoon Shakers).

Commanded, H. E. Emberlin, Humberstone, Leicester (Blue Brunswick); A. Heath, Caine, (Frillbacks.)

JUDGES.—*Poultry*: Rev. R. Pulleine, The Rectory, Kirby Wiske, Thirsk; G. J. Andrews, Esq., Dorchester; Mr. J. Baily, Mount Street, Grosvenor Square, London; J. H. Smith, Esq., Skelton, Grange, York; Mr. J. Hindson, Barton House, Everton, Liverpool. *Pigeons*: Mr. H. Weir, Lyndhurst Road, Peckham, London; Mr. T. J. Cottle, Pulteney Villa, Cheltenham.

STEWARDS.—G. C. Adkins, Esq., Mr. W. B. Mapplebeck, Mr. W. Lort, jun., and Mr. F. Sabin.

SUPERINTENDENT.—Mr. R. Shockley.

The following is a statement of the receipts, number of persons admitted, and number of entries in the present as compared with former years:—

POULTRY CLUB MEETING.

A MEETING of the Poultry Club was held at the Bingley Hall Tavern, Birmingham, on the 28th ult., present Messrs. Tudman, Munn, Boyle, Guy, Challoner, Robinson, Dolby, Anderson, Zurhorst, Tegetmeier, C. Lister, Teebay, Rev. F. Taylor, Crossland, T. H. Ashton, Pearson, Monsey, Swann, Maples, Lane, J. K. Fowler, Harvey, Wood, Mason, Powers, Pettis, and some others.

Mr. Boyle having been called to the chair, and a balance-sheet showing a favourable balance of £22 4s. 8d., handed round, the minutes of the last meeting (of which an account was given at page 317), were read.

Some remarks having been made on the conduct of the Secretaries, Mr. Tudman said that he found the Club an enormous undertaking, and wished to be relieved of his office, he thought that what had passed was equivalent to a vote of censure on the Secretaries (No! No!), and he therefore begged to resign.

The Chairman said he was sorry to hear it, but if Mr. Tudman had made up his mind to do so they must bear the loss. Perhaps Mr. Munn would act.

Mr. Munn (the other Secretary), said there was actually more work with two Secretaries than with one. He had been looking through the letters from Mr. Tudman, and found that there were upwards of fifty, besides those which had been destroyed at the time they were received. He certainly could not undertake so large an amount of business; he therefore begged to resign, and hoped that they would appoint some other good man.

* The amount received for the working-class tickets is not included in this statement.

The Chairman moved that the resignations be accepted, when Mr. Tegetmeier said, he believed it was out of order for such a motion to proceed from the chair, and begged to move, as a matter of form, that the resignations be accepted. This was seconded by Mr. —, who stated that he did so with very great reluctance, but he thought the Secretaries should know something of the business with which they were connected. He quite understood the difficulty of corresponding with each other.

Mr. Tudman said that much rested with Secretaries, and thought they ought to have discretionary power. Whoever they had for Secretary should have discretionary power. Something should be said about the price of the Rules, only fifty had been printed, and these had been sent to members, with the exception of such as were required by judges.

The resignation of the Secretaries was then accepted.

Mr. Zurhorst then said, he had had something to do with bringing about the resignations; he was aware that the Secretary of an institution like this had much to do to please all, but whoever undertook the office it should be thoroughly and properly fulfilled. At the last meeting there were no minutes and no balance-sheet. (Mr. Tudman here said, with reference to the latter, the funds had to be considered, the Club was yet in its infancy.) The Club had no press assistance, and without a head they were now in a "very great fix." Mr. Munn might consider writing fifty letters a very great difficulty, but many men did so and thought nothing of it. If the work were too much the next Secretary should have a paid assistant. There were many complaints now about letters not being answered, but if they paid an assistant they could hold him responsible. He had no doubt such an one would be found. Although the Secretaries had not done all that was possible, and the Club had got in a bit of a mess, he moved a vote of thanks to them, and this being seconded by Mr. Tegetmeier, was carried unanimously.

Mr. Tudman was then elected Treasurer.

Mr. Munn next entered into some explanations regarding the revised Rules not being published, and the difficulty the Secretaries laboured under in reconciling the differences of opinions which had been expressed by those to whom they had been submitted.

Some discussion then took place as to who was to go through the book and opinions on it, and how this was to be done.

Mr. Zurhorst proposed a sub-committee for the purpose, and named Messrs. Teebay, Dixon, and Challoner as fit persons to act, and moved that they be requested to revise and consider the Rules when they met at the Manchester Show, and this motion was carried.

Mr. Munn said the next business was to elect a Secretary.

Mr. Zurhorst proposed Mr. Dolby, and was seconded by Mr. Fowler.

A motion was then made that the present Secretaries be invited to act till the Manchester Show; and Mr. Munn said, as there was some difficulty in choosing a fresh Secretary, if the Club would allow him he would be Secretary for another year, provided Mr. Dolby were permitted to assist him.

Some objection was made to Mr. Dolby's residing at Dublin, as being likely to cause delay in correspondence, when Mr. Dolby said it was only one day's post to Dublin.

The motion was then put that Mr. Dolby be appointed Secretary, and carried by a large majority.

Mr. Munn said their next business was to elect Stewards for the ensuing year. Captain Hornby, R.N., had refused to act, and Mr. Hyde was disqualified for re-election from non-attendance.

Mr. Harvey thought so many Stewards cumbersome; he did not know where there were so many who had done so little. It was much better to have two or three in whom they could place confidence than twelve or fifteen.

Mr. Ashton said there were four or five Judges who were *ex officio* Stewards.

The following gentlemen were then elected Stewards—viz., Messrs. Fowler, Ashton, Munn, Kelleway, Stretch, T. P. Wood, Hawkesley, Zurhorst, Boyle, Eden, Crossland, and Beldon.

Mr. Wood proposed Mr. Tegetmeier as one of the Judges of Pigeons.

Mr. Tegetmeier thought that such a meeting was neither the proper time nor place for the election of Judges; he considered that if the meeting elected him to the office it would be a mischievous precedent, and injurious to the best interests of the Club; for the election of Judges should not be left to a single meeting, but to the Stewards.

Mr. Munn then proposed a vote of censure on the management of the Birmingham Show in respect to their selection of judges; and the motion having been seconded by Mr. Tudman, was carried unanimously.

The minutes of the last meeting were then confirmed, and the proceedings closed with a vote of thanks to the Chairman.

The following were proposed as new members of the Club at the meeting, and subsequently during the Show—viz., Messrs. E. Brown, Monsey, Carless, F. Else, M. Headley, T. Colley, C. Lister, W. J. Cope, R. Swift, W. H. Oates, F. Esquilant, J. A. Briggs, C. Maples, jun., R. Woods, J. Staley, and G. Manning; Rev. F. Taylor, and Sir R. Clifton, Bart., M.P.

CHIPPENHAM POULTRY SHOW.

HAVING walked, according to my annual custom, through this Show, peeping and peering into each pen, noting excellencies and defects, I now sit down to give a fair and unbiased account of the same. The Show this season was the largest ever known at Chippenham. It might be larger; but the Committee fear if they advertised it extensively they should not be able to accommodate all the poultry that would be sent. I own I think this wrong, for room might easily be made for fifty more pens.

The next point I would notice is that the birds were exceedingly well judged by Mr. Rodbard. I had the pleasure of walking round the Show with that gentleman after the prizes had been awarded, and in my humble opinion never were prizes awarded more fairly and correctly.

I was sorry to see that there was a falling-off in the quality of the Game birds shown. Now, it is not enough that a bird is a Game cock, but none that is not at any rate a tolerably good Game cock should be sent to any show. But proceed in due order according to the catalogue.

Dorkings, eight pens, good birds. Mr. Peacey, of Chelworth, first prize; Mr. F. Bailey, of Calne, second. *Spanish*, three pens. Mr. A. Heath, of Calne, won first with a good pen. *Game*, Black-breasted Reds, eighteen pens. Miss Elling, of Sutton Parva, had the first prize, and her birds were by far the best. *Game*, Any other variety, five pens. One good one of Brown-breasted and the prize Duckwing cock was a nice bird. *Cochins*, four pens. Mr. W. Bowley, Cirencester, first prize, and Miss Julia Milward second, in both cases good birds.

Next came the *Hamburgs*, and here was a great improvement, there being fourteen pens instead of the four only of last year, ten additional of the best egg-producers. The first prize in both Silver-pencilled and Silver-spangled went to Mr. Hulbert, of Chippenham, and both were good pens. In Golden-pencilled and Golden-spangled Mr. Maggs, of Telbirn, was first. *Polands*, three pens. Mr. J. Hinton, of Hinton, took first prize with an excellent pen of Silver-spangled; and Mr. Hulbert, of Chippenham, was second. Next we had eight pens of Any other distinct or cross breed. Mr. J. Hinton won first with his *Brahmas*. *Bantams*, *Game*, five pens. Mr. Renny, of Chippenham, had the first prize with a charming pen of Black-breasted Reds; the hens were particularly good. Mr. E. Cambridge was second with birds of the same kind nearly as good, the cock perhaps even better. In *Bantams*, any other variety, three pens, Mr. Cambridge was first with Blacks. Thus there were eight pens of *Bantams* in a show consisting of just one hundred pens. Well, the tiny pets came off not amiss. I shall soon think that the poultry world is beginning to agree with an enthusiastic Bantam fancier, who declared to me that "they were the most profitable of all fowls, for they ate nothing and produced abundance of eggs." This is better than the *ex nihilo nihil fit* of one's school days. *Turkeys* one pen, the very good ones belonging to Miss Milward; but because there was no competition only a bounty of ten shillings was given instead of the prize. Was this quite fair? *Geese*, four pens. *Ducks*, Aylesbury, five pens, good. *Rouen*, six pens,

very good. Any other variety, four pens. In this class Mr. G. S. Sainsbury, of Devizes, took first prize with an excellent pen of Blacks.

Last of all came Sweepstakes for the best Game cock, fourteen entries, and only one superior one of the whole fourteen—viz., the prize belonging to Mr. R. Elling, of Sutton Parva. Of the rest there was one good one, which was highly commended; its owner was Mr. Henry Stevenson, of Chippenham.

Such was the Chippenham Show—a pleasant little Show always. The visitors were numerous, and the ladies as usual left the fat pigs to themselves (by the way, why is not a pint of eau de Cologne sprinkled each hour over these creatures?) and any male who stood long in front of a pen, as I frequently did, was in danger of having his calves rasped by crinoline, and, what was worse, being considered very much in the way.—WILTSHIRE RECTOR.

MURDER AMONG DUCKS.

I KEEP my poultry inside a wired yard, from which they can get in or out of their houses at pleasure. Amongst them I have Aylesbury and Rouen Ducks, and some time since having a few Muscovy Ducks I put them into the same place, when the latter were attacked one night by some animal and killed, the blood being sucked through a deep hole in the neck. Since then the other Ducks have been unmolested, but having got a few more Muscovy Ducks a day or two since I again left them in the same yard, and this morning I found three of them killed and three others wounded. This time an Aylesbury was attacked as well, and its feathers gnawed off in a singular manner. All the dead Ducks were killed by a wound in the neck, but those wounded had their feathers gnawed off. The question I wish to ask is, Do you think that there is any particular odour about the Muscovy which would attract a weasel, as the hole in the neck leads me to suppose that he was the robber, although the gnawed back and feathers point to some other vermin?—AN OLD SUBSCRIBER.

[There is, unquestionably, a peculiar smell about Muscovy Ducks, but we have never heard that it attracted vermin.

Ducks do not make wounds or suck blood, but their fighting is always by biting at the back of the neck, and they continue to do so till all feathers are gone, and it is bleeding. A new comer on the pond would be likely to be thus treated by the old inhabitants, and such an one would be an easy prey to any vermin.

If not previously injured, a weasel would hardly overcome a Muscovy Duck, as she is strong and would take to the water.]

BRAHMA POOTRAS.

So much has been written in the Journal (which I take in regularly), on the subject of the origin of Brahma Pootras, that I feel I must add my little experience on the subject. So long ago as 1848 or 1849, a friend sent me some eggs which he called "Malays." The chickens, however, proved to be not "Malays," for they had feathered legs. It was before the rage for Cochins commenced, so I only kept one pair, and that more out of respect for the friend who had given me the eggs than from any particular fancy that I had for the "new breed," for such I really considered them to be.

From that pair I had one particular hen that had not only the feathered legs, but also the vulture-hock. I considered her something out of the common way, so preserved her eggs. From her I bred fowls varying in colour, and also in characteristics. One cock I sent to the Crystal Palace Show, where he was much admired, and I was told that if I had had pullets to show with him I should have gained a prize.

The birds I have now, all arising from this original pair, are decidedly Brahma Pootras; are very hardy, excellent layers, gentle in temper, and good mothers. They vary, however, much in colour, but are chiefly white, with black hackle and tail, are tall handsome birds, and are generally more or less vulture-hocked.

If this will in any degree help your readers to the settlement of the vexed question of the origin of Brahma Pootras, I shall be happy. My own opinion is, that they are a mixed

breed, but by selecting and keeping only the best specimens they will, ere long, become a decided breed.—A. G.

P.S.—The bird shown at the Crystal Palace I have still (stuffed), he having died shortly afterwards. He was white, with black hackle and tail, vulture-hocked, and feather-legged.

If I cannot give any further information I will reply to any notice among your answers to correspondents with which you may favour me. One thing I must add, that my birds do not crow with the prolonged howl of the Cochin-Chinas.

SATINETTE PIGEONS.

I HAVE noticed in one of your Numbers the remarks and opinions of Mr. B. P. Brent respecting the Satinettes, which breed I only have imported in this country, and I bred those so successfully exhibited in almost every show in England for the last two years. I now possess the original imported birds with other young ones of them, by far superior to those exhibited and so much praised.

Allow me now to inform Mr. Brent that the Satinettes are quite a distinct variety in their native land, where I have seen them in large numbers as much as fifteen years back, and there are three different varieties in colour, and I possess all the three. The thoroughbred Satinettes ought to be with feathered legs, and cannot be had with cap at all. I hope Mr. Brent will be satisfied after this, that the Satinettes are quite a distinct breed and far superior to Turbits with which they will not hold any relations.—H. NOYE.

NOTES BY AN OLD FANCIER AT THE SOUTHAMPTON BIRD SHOW.

In the first place the foreign birds and stuffed specimens were a show in themselves, and well worth a day's journey to see. I certainly expected to see more Canaries and British birds. The latter were very scarce; and I think too much is charged for entry, seeing one prize is only given, and that of a very small amount. Of course, I heard much grumbling—amongst disappointed exhibitors, I suppose, but I could see plainly, that some of the awards were unfairly made, and will give some of the cases in which I dissent from the decision of the Judges.

The Clear Yellow and Clear Buff Norwich justly received the prizes given them. The "worst" bird in the Norwich Variegated Buff received first prize, whereas Mr. Walter, of Winchester, and Mr. Mackley, of Norwich, ought to have had first and second. The Gold Lizards were a nice class, but No. 32, which ought to have had first prize, was only highly commended. In the groups of Norwich, too, the prizes should have been reversed. Mr. Walter's birds were a better colour than those of Mr. Mackley. The greatest mistake, I consider, was made in the Clear Yellow Belgian Class. The "best" bird in the class, or in the Show, only received a high commendation, and it must have been very annoying to the exhibitor, Mr. Triggs, of Landport, to have been passed over. A different result will ensue if these birds meet at any other show, and I hope they may. I am not singular in my opinion, for I met many old and respected fanciers at the Show, and we compared the birds together; among them were Mr. Judd, of London, no mean judge, and many others whom I read of in your columns; and last, though not least, was one of the respected Judges of the Crystal Palace Bird Show, Mr. Moore. The prizes should also have been reversed in the Belgian groups. I could only see "two" birds in the first-prize cage; whereas, "three" were in the second cage. I am afraid there was not enough time allowed to the Judges to do their work properly, for at this time of the year it is dark till a late hour in the morning and the exhibitions generally open about twelve.—RICH'D. TAYLOR, Portsea, Hampshire.

OPEN DRIVING.

DURING the past autumn I have driven bees very extensively without confining them in any way, somewhat in the manner advocated by "J. W. G. C." in page 372 of the last Volume of THE JOURNAL OF HORTICULTURE, but omitting

the use of forked sticks, or any apparatus whatever except a fumigator, two empty hives, an empty bucket, and (for convenience) a couple of kitchen chairs.

My mode of operating has been as follows:—The bucket having been firmly planted on the ground, at a short distance from the colony to be operated on, a few puffs of smoke from the fumigator are blown into the entrance. When the bees retire the hive is slightly raised from its floor-board, and some whiffs of smoke blown under it from all sides. It is well, after doing this, to allow the stock to stand undisturbed for about a minute, so as to allow the bees to commence filling themselves with honey. The hive is then raised altogether from its place, and steadily inverted on the pail, when, having been covered with one of the empty hives, the whole pile, bucket and all, should then be placed on one of the kitchen chairs at a little distance, the other empty hive taking the place of the full one, in order to amuse the retiring bees. A stout carpetpin, or a hairpin, having been stuck into the outside edge of the full hive, opposite the ends of the combs, in order to prevent the empty one from slipping, I seat myself on the second chair, keep one side of the empty hive raised at an angle of nearly 45° with my left hand, whilst I rap the full one with my right, keeping a sharp look-out under the uplifted hive for the ascending queen.

After practising this system with upwards of a score of condemned stocks, I have come to the conclusion that it is, on the whole, slower than close driving, whilst, on the other hand, it has the advantage of affording a better chance of securing the queen during her ascent.

It is all very well for an old stager like myself, who experiences no more ill effects from a bee's sting than from the prick of a pin or needle, to practise open driving without protection for either face or hands; and it is, without doubt, very amusing to witness the admiration and astonishment of the uninitiated spectators; but to the inexperienced I would offer a word of warning and advice, and that is—never attempt open driving without the protection of an efficient bee-dress and gloves. Most bees are unquestionably taken by surprise when the matter is well managed; but this is not invariably the case, and in one misadventure, with a wide-awake colony, you may chance to receive such punishment as will make you regret neglecting the precautions recommended by—A DEVONSHIRE BEE-KEEPER.

DEATH OF A QUEEN.

WILL you, if possible, answer the following question? A dead queen has been picked up from before a strong hive (stock). Fearing the consequence, I shall gently smoke them, turn them out, and examine for a queen. If I find one, well and good; if not, I shall unite them to the next hive. I have taken the precaution to bring the hive into a milder temperature for a day previous to operating.—JOHN NEWLAND.

[The death of the queen may have occurred from natural causes, or she may have been killed by her own workers, or may even have fallen a victim in single combat with a young queen, which is sometimes, although very rarely, hatched under the most inexplicable circumstances, as related by Mr. Woodbury in page 157 of Vol. V., New Series.

In either case it will be advisable to unite the bees to the next stock; but the utmost care should be taken to remove a young queen should any such chance to exist, and for this reason—she might very possibly be victorious over, and dethrone the prolific and rightful monarch of the hive into which she is introduced, which misfortune would ultimately prove fatal to the entire colony, since, at this season, she could not obtain impregnation, and must, therefore, persevere remain a virgin, and turn out a drone-breeder, should she survive until the spring.]

JUMPING COWS.

LOOKING over the index to THE JOURNAL OF HORTICULTURE of the day, two or three weeks ago, I saw with delight a reference entitled "Jumping Cows," and following it up found that some farmers' club or other great authority, proposed as a tried and successful method of taming these over-

active members of society, to cut their upper eyelashes, which they, or he, affirmed to have done successfully with oxen and steers. Now, we have a cow whose habits are so highly gymnastic, that she not only clears fences with extraordinary agility, but attempts to stand on her head on the other side. Of course, the experiment was too easy not to be tried at once, and for a week or ten days we watched the cow and blessed THE JOURNAL OF HORTICULTURE. But, alas! yesterday, finding only an iron-hurdle fence between her and an alluring bit of garden, a promising crop of Brussels sprouts proved too much for her feelings, and—over she went.

Now, Mr. Editor, will the want of eyelashes make her proof against every other temptation except Brussels sprouts? Or can you suggest any more successful mode of bringing active and greedy cows to reason? If so, you will oblige your constant reader and some time correspondent.—COCHIN.

[Well do we know the temptations held out by Brussels sprouts, and well do we know a gardener's feelings when he finds a cow ruthlessly stripping the stems. So when we read in an American journal that the preventive of such raids was so simple, we hastened to reveal it to our readers. (Ah, "COCHIN," "BRAHMA POOTRA" will say, it is only like that other Yankee tale about myself.) However, our correspondent may effectually restrain the gymnastics of her cow within permissible bounds by either hanging a piece of sacking before the eyes of the cow so as to prevent her seeing directly before her, but not to prevent her looking on the ground, or a tether may be strapped from the fore foot to the hind foot on the same side.]

PRESERVING BACON.

WHAT are the requisites for keeping bacon and hams? Are they best kept sown up in bags, hung up, or on racks? where there is much air or little? What degree of heat? Is it a good plan to put them in boxes filled up with malt combs?—R. B.

[I can best reply to these questions by drawing upon our seven years' experience in this house, upon the subject of bacon. The only time the fly troubled us, was when the fitches were put into bags; hence we have never used bags again. We hang the fitches on hooks built into the wall, on the side of the kitchen on which is the fire. It is an airy kitchen, having three doors in it. We put a piece of stick an inch or more in diameter between the fitch and the wall, this secures a current of air at the back. The heat though much tempered by the airiness of the kitchen, must be considerable in a place where cooking is daily done for a large family. By the way, in summer the fitches are hung up in the entrance to the kitchen, for there the temperature is lower. I dine occasionally with a friend who has his bacon kept in a box filled up with malt combs, but although I eat his fowls, I shun the bacon that accompanies them on the table, for it is always bad.—WILTSHIRE RECTOR.]

OUR LETTER BOX.

BIRMINGHAM PEIZE LIST.—Captain W. Hornby took the second prize in adult Dorkings, and not Sir J. D. Wauchope, as stated in our list of last week.

HENS EATING EACH OTHER'S FEATHERS (*J. C. L.*).—It usually arises either from improper food, as flesh, which gives an unnatural appetite, and if withheld causes them to eat feathers as the nearest substitute; or from dry, hot, stimulating food, which produces a fevered state of the inside. The treatment is the same in both instances. Ground food slaked with cold water, plenty of grass and lettuces if to be had. Rub the bare spots with compound sulphur ointment.

CHOICE OF POULTRY (*Yorkshire*).—Continue to keep your Dorkings running about, and have some Spanish, Cochins, or Brahmas to shut up as layers. They will do well in a very small space.

BLACK INDIAN DUCKS (*Cochin*).—The bill of the Duck should be black. That of the drake dark, nearly black, with a yellowish tinge underneath. The legs should be as nearly black as possible, the only deviation being an orange tinge. The latter is not desirable.

ASTHMATIC CANARY (*P. M., Nottingham*).—Your Canary is evidently suffering from asthma. Tar water has been found beneficial. One gentleman strongly recommends rice water. The last case I had was cured by giving Spanish Liquorice in the bird's drinking water, and the bird is now as healthy and vigorous as ever. Flowers of sulphur is not injurious to the birds. The little work on the Canary and British Finches has been published some time, and can be had free by post from the office of this Journal for nineteen stamps.—B. P. B.

THE TIMES BEE-MASTER (*Crito*).—We are obliged by the note on his classical errors in other publications, but they are such as we must avoid in our columns.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 45.6°, and its night temperature 33.7°. The greatest heat was 62° on the 16th, 1840; and the lowest cold, 18°, on the 15th, 1848. The greatest fall of rain was 1.24 inch.

POTATOES.

OME fourteen years ago I was asked by a countryman of mine, a Suffolk farmer, to dine with him. On parting with my friend he gave me a general invitation. "Come," said he, and dine with me whenever you like—stand on no ceremony, for I have always a change for dinner,—pork and cabbage today, cabbage and pork

to-morrow." I well remember my friend was in despair about the Potato, and our argument for and against the ever-to-be-desired esculent waxed long and rather loud; but both of us were bachelors, so the word "Hush!" never had any occasion to become impressed upon us to restrain our volubility. The old housekeeper did not interfere beyond a few smiles, as I expounded to my friend my system of cultivating the tuber, and my confidence of corporeal sustentation from that particular produce up to the natural term of my existence. I sent him some samples for seed, and the result was that eventually my friend included Potatoes in his bill of fare. Poor fellow! he is now gone to that "bourne from whence no traveller returns to tell a tale;" and I am left to repose on my laurels with so much of vanity as an obscure grower of Potatoes may feel himself entitled to lay claim to, and once more through the genial medium of these pages make my annual bow, in order to detail my proceedings with my favourite vegetable.

I planted thirty-four varieties (not including seedlings), of the Potato in the spring of this year, nineteen sorts only of which do I think it worth while to give an account of. Inquiries are often made by correspondents for the Potatoes most suitable for particular modes of cultivation: therefore I purpose to divide my subject according to the wants of different cultivators, and so enable them to know at once the sorts most suitable for the frame, the orchard-house, the garden, and the field, giving those kinds precedence which are in my estimation worthy to stand first.

THE FRAME.

No. 1. *Mitchell's Early Albion Kidney.*

No. 2. *Sutton's Racehorse.*

These two sorts are scarcely distinguishable apart. They make small glazed haulm, are good croppers, of excellent flavour, and both attain the desirable quality of firmness of tuber at an early stage of their growth.

No. 3. *Shutford Seedling* (Round).—A diminutive glazed topper, preocious, a good cropper, of excellent flavour, though having the undesirable property of producing too many little ones. I am not aware that I carry the appearance of a Potato, but I constantly find

myself discoursing about the tuber with entire strangers most unaccountably; and I well remember the information I gained as to the origin of the above. Some years ago, as I was journeying by rail, from London to Woodstock, a substantial farmer-looking person and myself having enumerated to each other our approved sorts, I came to speak in praise of an early Potato I had met with a year or two before called the Shutford Seedling. My fellow traveller agreed with me, and, curiously enough, he said that he was then about promoting some kind of testimonial to the worthy man who raised it, who, he said, was the parish clerk of the village of Shutford, near Banbury.

THE ORCHARD-HOUSE.

No. 4 is a round early Potato. A sample was sent me this spring to prove against my early English kinds by Mr. Thomas Hogg, Coldstream, N.B. For orchard-house cultivation I do not know any kind which would be more appropriate. As an early Potato for the garden, and in regard to its freedom from eyes, handsome good-sized tubers, and weight of crop, it is a great step in the right direction; and we have no Potato in cultivation that can beat it for flavour, though, like our best earliest sorts, it has a yellowish cast of flesh. As to its keeping properties, I can say that the tubers I received from Scotland last March were in condition for table, and some of my produce on this 29th of November is as good as it can be. It has a rich, unique, moderate-sized top, soon disposed to droop and hug the ground—too spreading, I fear, for frame work. It produces a profusion of pink-coloured flowers, and every blossom gives a berry: consequently they should be picked off in their infancy, unless it be determined to preserve some for crossing with, to which purpose I intend to devote a few, for I predict it will prove a good kind to cross with the pollen of some of the best of our English white-fleshed second early varieties:

No. 5. *Walnut-leaved Kidney.*—A well-known Potato, which bears a larger top and tuber. It takes rather longer to arrive at maturity, and does not produce so many tubers to a root as Nos. 1 and 2; nevertheless, it is a good kind, very nearly allied to them.

No. 6. *White-blossom Ashleaf.*—This variety produces but a few fine Kidney Potatoes to a root, and on that account will doubtless long remain a favourite. It is the best kind to forward by preparing its young shoots, one "spurt" generally becoming a monopoliser, which before planting can be made to attain substantially a length of 5 or 6 inches, by placing at this time of the year the tubers in twilight, in single layers, in a temperature of about 60°, to be then planted in large flower-pots, rough boxes, or many other descriptions of utensils. These may be placed in out-of-the-way corners into which light and sun can penetrate, for the plants to produce. It requires to be nearly ripe before it is up to the mark in flavour, and I consider it inferior in that respect to the sorts mentioned above. It produces rather tall tops with but little and crumpled foliage and white blossoms. Just

favour it with moisture and ward off the frosts, and it will cater for itself easier than most kinds. It would suit orchard-house culture well.

It would occupy too much space to give the particulars of the above in detail from my note-book, but on referring to it I find that the best roots from the earliest diggings averaged from half a pound up to $2\frac{1}{2}$ lbs. on the 19th of July, when the six kinds growing side by side were quite ripe and taken up. Mr. Hogg's Coldstream Potato then gave $2\frac{1}{2}$ lbs. to a root repeatedly, but none of the others exceeded 2 lbs. for their best roots. In one instance a single tuber of the former weighed half a pound. I said last year that I intended to grow my early Potatoes for the future in beds; but I have kept to the ridge and trench plan as being most suitable for this ground, which is much shaded by the trees from Blenheim Park.

THE GARDEN.

No. 7. *Daintree's Seedling* (Round), Second Early.—This first-class Potato yielded me per acre this year, on an average, rather more than 16 tons, or 225 sacks, at 3 bushels per sack, when grown on the ridge, each ridge or row being removed 42 inches, or exactly between the sites of the rows where I grew the same sort last year, that patch of ground having been now seventeen years under Potato culture.

No. 8. *Daintree's Newest Seedling* (Kidney), Second Early.—I have this year given this Potato a fair trial, and with me it proves to be as like the Lapstone Kidney as Sutton's Racehorse is to Mitchell's Albion. In their flavour and appearance in the dish when cooked, I cannot distinguish the one from the other. In the character of their haulm when growing they are exactly alike, though I must say that with me they "run out" more uneven in tuber than the Lapstones; and even that excellent kind is by no means to be praised in that respect. I shall carefully select the handsomest tubers for seed, which will tend to counteract the tendency to grow of all shapes. I cultivated four square yards of ridge with this seedling, and it gave nearly 27 lbs. weight of tubers. Others, I believe, have it on trial, and I hope to have their reports. I intend to continue to grow it, for, given an equal quality in two Potatoes, it is always preferable to propagate the newest bred as being better able to stand out against the ills that the Potato is subject to.

No. 9. *Lapstone Kidney* (Second Early).—Produce about 15 tons per acre. This is the kind that I have previously depended upon as my latest and best keeping sort. I have a fine sample of them.

No. 10. *Fortyfold* (Round Mottled Blue), Second Early.—Quality first-rate; it is fit for table only up to the new year. It is the best of all Potatoes for mashing. It never cropped better with me than it has done this year. It is a very old favourite of mine, though I dare not grow it largely owing to its being so liable to disease. I am happy to say that I have not met with a single tuber in that condition this year.

No. 11. *Jackson's Seedling* (Scarcely a Second Early).—This is an excellent long-keeping Potato, more delicate to eat than even the Lapstone, not being quite so harsh-dry, if I may coin the word; but its growth of top though handsome is extensive, and it flowers profusely and is very much disposed to berry, both of which circumstances are drawbacks when space and time are limited. It is pear-shaped, and much upon a par for bulk of cropping with the Lapstone.

No. 12. *Fluke*.—There are many spurious kinds of this Potato about, as it is an excellent mother, and it has been largely and indiscriminately propagated from. I believe that I have the true Fluke. It has a dark spare foliage, a meagre top, with blossoms mostly disposed to berry. It is a very useful sort in the event of the disease occurring early, for being a late hardy Potato, it is then likely to escape it, otherwise it is no particular favourite of mine for the table. I have been publicly found fault with for calling it a coarse variety. I have it as good as it can be this year, but as a cropper it is not what it used to be. The first four of these were taken up on the 20th of August; the latter two on the 12th of September.

THE FIELD.

No. 13. *Sutton's Finest Regent* (Round), Late.—This is an excellent Potato of its class. I singled it out two years

ago from a number of sorts at Messrs. Sutton's Seed Establishment, at Reading. It is an improvement I think on all its numerous relations, being not so deep-eyed, and in shape rather oblong than round. It is not quite so acid in its farewell upon the palate as most Regents are. It throws up in this garden a monstrous top unmistakeably Regent in appearance. Its average was with me between 16 and 17 tons per acre, and every poor man who can should procure it.

No. 14. *Freebearer* (Late).—This is a large, mottled-coloured, ugly Potato, and eminently suitable for a poor man's patch of ground. It produces very few small tubers, weighs heavily in the scales, quickly fills the measure, and its flesh is white, rich, and good. This and the following four sorts with other field varieties, I could not find room to cultivate to any extent, for their tops in this ground become in size like Hazel bushes, so I confined their culture to three large sets of each kind, merely to find how the results tallied with my previous observations, as to which of the sorts I considered the best for a field. When I write *field*, it must be understood that the kinds I recommend for that off-hand culture, would also prove suitable for any light poor garden ground where the finer descriptions of Potatoes do not answer in cultivation. The three roots of the above produced 23 lbs. weight of tubers.

No. 15. *Prolific* (Late).—A very good-flavoured white Potato and ugly. The three roots weighed $22\frac{1}{2}$ lbs.

No. 16. *Gryffe Castle Seedling*.—For features and properties like the last. The three roots weighed $24\frac{1}{2}$ lbs.

No. 17. *Walker's Regent* (Late). The three roots weighed $13\frac{1}{2}$ lbs.

No. 18. *Scotch Rough White*, is as its name implies. The three roots weighed $13\frac{3}{4}$ lbs. The last three sorts enumerated are some of those which I received in the Stewarton bee-hive (of which I hope ere long to tell a tale), which was sent to me from Scotland two years ago by a still unknown friend. I have discarded the other kinds, but these three I always hope to keep for remembrance.

No. 19. *Negro*.—A dark blue, flavourless, large, oblong Potato, suitable for the pigs and an immense cropper. I could not decide how it came about, but two out of the three of these roots gave way in midgrowth. At one we counted 113 infantine tubers, and at the other 131! The third root arrived at maturity and gave 16 lbs. in weight, and that is the heaviest root of Potatoes I ever grew.

THE FUTURE.

I have eight new seedling Potatoes selected out of fifty, and of which I have a good opinion at present, but which another year's cultivation may induce me to scatter to the winds. Unless a person is careless as to what rubbish he brings into cultivation, I scarcely know any kind of propagation which requires more care, observation, time, and patience, than raising a first-rate Potato. From its first impregnated blossom to its appearance satisfactorily on the dining-table it takes at least four years to do it properly, and supposing ninety-nine seeds to germinate out of one hundred, after the years spent in constant attention, possibly not one of the progeny out of the whole batch will be found worthy of perpetuation. Poor Beaton, whom I have never ceased to regret, used to say, that it was "easier to grow Pine Apples than a good Potato now-a-days." I should say that it is easier to do so than to raise a new variety. Thirteen out of my fifty seedlings I had sent me by my unknown friend from Scotland. They scarcely weighed an ounce when I received them in a small envelope, and they were stated to be seedlings from the Fluke. I had thirty-seven seedlings of my own and of the same age, the produce of the pollen from the stamens of Jackson's Seedling, dusted on some pistils of the Fluke. Now, out of these, after three years coaxing, I have only eight worthy of another year's trial, four out of the thirteen from Scotland, and four from my own, and if two of them turn out what I consider Potatoes ought to be before they are recommended to the public, I shall consider myself fortunate. I forward you samples of the eighteen kinds above enumerated in order that you may prove them by tasting, and state if you please whether you consider the ridge-and-trench plan still continues to produce tubers with flavour quite up to the mark.

—UPWARDS AND ONWARDS.

EARLY PEAS.

At a time when public and private enterprise seem determined to leave nothing untouched that there seems any chance of improving, it is not to be wondered that Peas have also come in for their share of the universal progressiveness, which whether real or ideal is constantly at work. Unfortunately, every assumed advance does not prove to be so, and now and then an absolute retrogression takes place; but, on the whole, progress is made, or what is almost an equivalent thereto, a backward tendency is prevented by the movements of those whose efforts are directed to the improvement of the varieties of fruits and vegetables so numerously put forth year after year. That Peas have been no exception to this rule I need hardly affirm. On the contrary, each returning season adds one or more kinds to the class of early ones, and two or three, perhaps, to that of general croppers. On the latter section it is not my purpose to make much comment at present, but I will take the former as possessing claims to attention which cannot be overlooked by even the most careless of cultivators. It will, therefore, be no waste of time to examine the conditions which favour earliness in this vegetable, as well as to name some of the kinds most suitable in this respect.

In the first place let us take a survey of the district which has the reputation of furnishing earlier Peas than others equally favourably situated as regards latitude and local shelter, and one of the main features which constitute early maturity will be at once apparent. Some few years ago I visited a nobleman's gardener who had an extensive kitchen garden as well as other grounds to manage. The kitchen garden had the reputation, and deservedly so, of being one of the best in the neighbourhood; it comprised an area of some six or seven acres, and had good walls all round, and one or two crossing it in a transverse direction, with external shelter on the west, north, and east sides, while the soil was of a kind that produced some of the best vegetables and fruits in their season, and the whole was well managed. Of course, early Peas were always aimed at, the various modes by which they are expected to be obtained adopted, and all the new kinds sown which are every year offered; but the gardener candidly told me, and the admission did him honour, that one of the tenants on the estate always gathered a dish of Peas in the open field earlier by four or five days than he could from the garden, although he had adopted the most approved methods of obtaining them. He had planted them on a south border, and had tried the various methods of autumn and spring sowing, and planting out in various ways; but the result in six out of seven years was always in favour of the farmer.

Now, this may raise a doubt that something was wrong, though the garden was really a good one. The walls produced good Peaches, and the open quarters excellent vegetables, Strawberries, and other small fruits, and skill and good cultivation were everywhere visible; but Nature had denied the garden the means of maturing a crop of Peas early in the season. The soil was heavy, stiff, and cold, useful qualifications for a summer garden, as the general crops testified by their good appearance, but adverse to the winter and spring growth of such vegetables as have to make their growth then—as the Pea has to do. I need hardly say that the garden was well drained in so far as mechanical means could accomplish that object, there being no stagnant water for artificial conduits to take away, neither had good cultivation left anything undone to secure the speedy sinking of rain water. The subsoil was stiff, an excellent qualification by-the-by for nine-tenths of the crops cultivated in the garden, taking everything into consideration; but, as before observed, adverse to the early maturity of Peas, while the soil which possessed the contrary qualification was deficient in most of the properties which rendered the other so serviceable in many ways—for instance, that of retaining moisture to supply the wants of vegetation in the dry weather of the dog-days. The soil which produced the early crop alluded to was of a light gravelly nature, resting also on gravel, which would drain off every drop of moisture which fell on its thin covering, and at the same time carry away those fertilising matters which might be artificially applied. In fact, a dry gravelly soil, which in local phrase is described as a hot burning one in summer, was the soil which pro-

duced the early Peas, beating those on the gardener's south border. From such ground London is supplied with basketfuls of early Peas at a time when they are far from plentiful in places equally favoured in all other respects than those of soil and subsoil.

It being shown that a dry, open, stony soil is the best to furnish early Peas, it follows that unless a soil of this kind be at command, an early crop cannot be depended upon, unless expensive operations be undertaken to imitate it, and such being seldom convenient, those having a stiff, cool soil must rest satisfied, that though unable to furnish Peas as early as their neighbour, they will most likely gain on him in summer Cauliflower, Lettuce, and many other things, as well as in the prolongation of the main crop of Peas. Something, too, may perhaps, be done to encourage the early maturity of Peas in unfavourable places, by adding large quantities of sand or sandstone shatter, if it can be had, to the stiff soil; and as much of the latter material as can be procured, put in the bottom of the trench, would do much towards improving the drainage, and increasing the power of the surface soil to absorb the heat of the sun in early spring. Manure, too, is less wanted for the early crop than for later ones, early maturity rather than prolonged growth being the object. It likewise happens sometimes that means taken to check growth are not without their benefit. Thus cutting the roots of Tomatoes in autumn checks the growth of useless vine, and hastens the maturity of the fruit, and in like manner where slates or flagstones are plentiful, a few laid along under the row check the downward tendency of the roots, and the plant being compelled either to send its roots farther for its food, or hurry on its functions, the latter being the more easily accomplished, a few days are gained in the crop. The soil should also be lighter than the surrounding medium, the row raised above the general level into something like a ridge, the slate or stone bottom but slightly depressed from the surface, and all the growing material raised above it. Observe, I by no means affirm that this method will insure success in all cases, but in some it may be beneficial, and is worth a trial.—J. ROBSON.

(To be continued.)

FUMES OF CHARCOAL AMONG PLANTS.

CUCUMBERS IN DUNG-BEDS—WINTERING COLEUS BLUMEI
AND VERSCHAFFELTI.

I HAVE a lean-to house 40 feet by 10 feet, but not heated, and in it I am obliged to keep all my bedding plants through the winter, and if a sharp winter some of the tenderest of them are severely cut, if not entirely killed. Do you think the fumes of charcoal would injure the plants at all if used merely to exclude frost? As that would, I suppose, be the only thing I could use, would it be injurious to heat the house with it a degree or two above freezing?

When would be the earliest time I could sow Cucumber seed with any hope of success? I should grow the plants on dung hotbeds, and should like to commence as soon as possible. I suppose the Improved Sion House is the best for early forcing.

I had a fine lot of healthy young plants of the Coleus Blumei and Verschaffelti, in three-inch pots in a cold greenhouse, but am afraid I shall lose them all, as several of them are already dead, and the others are dying off; the points of the shoots mildew, and the stems rot off, although they are kept almost dry. Would you tell me how I could winter these pretty plants?—A YOUNG GARDENER.

[Burning charcoal in an unheated greenhouse will always be injurious in proportion to the closeness of the house, and the nature of the plants. Some leathery-leaved plants, and even soft-leaved ones like the Scarlet Geraniums, will stand much more than any others. Merely to heat a degree or two above freezing, is rather close sailing, unless you stay beside your charcoal pans all night. Would it not be better for such a nice house at once to purchase one or two small iron stoves, which you might do for from 30s. to 35s. each, with a funnel to go outside? The advantage of two would be that you would never require to make either of the stoves very hot. If the house is not lofty, one fair-sized brick Arnott's stove would answer to keep out frost, and a pan of water on the top would give a nice moist atmosphere. We need say

nothing of a flue, or hot water, but it is a pity to trust a house of such a size full of bedding plants to the mercies of charcoal, unless, indeed, you burn it in a close vessel, with a small funnel to take off the fumes.

We presume you cannot cover the roof of your house thickly; and if you cannot do so, nor yet use heat, then the best plan for keeping plants in such a house would be the following, which we have several times adopted, when we could get no heat. The plants instead of being set on stages were placed in beds—say 4 feet wide, on the floor of the house, with 15 inches of a passage between the beds. A few sticks or wires were hooped over the beds of plants, which were kept rather dry all the winter. The roof would keep out a little frost. When more than a few degrees were expected, a mat, or a cloth of any kind was thrown over the hoops, and when the frost became more intense still, a few inches of rough hay, or dry litter was thrown lightly over the cloth or mat. Plants can be much more easily kept in such a house so heated, than in any mere cold pit or frame. If anything like attention is paid, the plants will scarcely ever suffer from damp, and all the attention necessary for them can always be given under cover of the roof. We have no doubt that in an unheated orchard-house, great quantities of plants may so be kept. We thus preserved many last season, and without a cloth, by merely using clean dry litter. If that dry material is turned over frequently, it will keep out much frost. All outside coverings lose their protecting power in proportion as they become wet and dense. Once we had a lot of fine plants on stages in such a house as our correspondent's, and an unexpected frost of a three weeks' duration having set in, the plants were saved by being all collected under the stage, and the stage covered round and over with cloths and matting, and when the thermometer under the covering fell to 34°, then 4 inches of litter was placed all over. The plants remained thus shut up until the frost was gone, and suffered much less than they would have done had frost been kept out by pans of burning charcoal.

As to the time of sowing Cucumbers for fruiting in dung-beds, you may commence directly, if you can obtain dung enough to carry you on. In sowing, you may have a bed fully 3 feet in height, and from 12 to 18 inches larger all round than the frame. A one-light box will be as good for this purpose as a larger. The plants will then be advancing whilst you are preparing material for your fruiting-bed. With covering up you should be able to command 70° of temperature. We need not say that the heat must be sweet, which you will know if the condensed moisture on the glass is as clear as dew drops. For a good bed to carry you through the spring and summer, it would require to be at least 4 feet high at back, and 3½ feet in front, and to keep the air inside dry and sweet, we prefer banking up litter to the top of the frame all round. Much of the success will depend on having a dry or waterproof covering. When in our young days we used to grow Cucumbers in winter and spring in dung-beds, we liked to have double sashes to use when we wished, and also for the purpose of changing the sashes when they became at all dirty. This was easily managed by having two-light or three-light frames, two at least of one size. It was only during the worst months of the year that we found changing the sashes advisable. Instead of attempting to clean a sash in use, it was taken off in an instant, and a dry clean one put on as quickly. With plenty of manure, sufficient labour power, and an extra amount of care and attention, Cucumbers may thus be grown early as well as by hot water; but constant attention must be given to keep up the temperature, and a wholesome atmosphere.

You will not succeed in keeping Coleus Blumei and Ver-schaffelti in your cold house. If you heated the house you might keep them by having a box made in which to place the plants, with a hand-light, or a large square or two of glass over it. By some means you must give a rather dry temperature of from 45° to 50°. We think you may keep them in your living-room more easily than in an orchard-house. An amateur kept a lot last season according to our directions. The plants were small, struck in August, and potted in three-inch pots; others were struck about the end of September, four or five round the sides of a four-inch pot, and were left in the cutting-pots all the winter. He

had for these and similar things two rough boxes, made 18 inches deep, and 2 feet square, a bottom of zinc was placed 5 inches from the bottom of the box, the place beneath had putty placed all round the sides at the joints, and then the whole below the zinc was well tarred, and done time enough to dry well before being used. A simple plug-hole was left at the top and bottom for pouring in hot water, and letting it off when cold. Little bits of wood for placing the pots on were set inside, and the top of the box was covered by two squares of glass laid on. In severe weather the glass could be covered. When more severe still a little hot water from a teakettle would heat the enclosed space through the zinc, and the bits of board free of the zinc prevented the pots being over-heated. Something of the same contrivance would do in the cold house, but, of course, it would be more easily looked after in a dwelling-house. Such little boxes, rough or elegantly made, would also be valuable to amateurs for propagating.—R. F.]

ROSES SUITABLE TO THE NORTH OF ENGLAND, IRELAND, AND SCOTLAND.

THE article on pillar Roses for a conservatory (page 110), has been read in Ireland, and acknowledged by a distinguished countess; and I have thought that it might be of advantage to the northerns of England, and also to persons living in Scotland and Ireland, if I gave a list of hardy, excellent, free-blooming Roses suitable to their circumstances.

As their countries are either cold or humid, their summers short, and their winters severe, I advise them to get some of the Roses named beneath, on the hardy, quick-growing Manetti stock. Those in italics are rather for ornament than show. Those to which an asterisk is prefixed may not open well in humid cold seasons, or late in the season, unless they are under south walls. The Roses recommended are equally good for all parts of England.

SUMMER ROSES.

WHITE.—Madame Zoutman, *Madame Plantier, Triomphe de Bayeaux.* **FLESH-COLOURED.**—*Mad. Audot.* **VARIEGATED.**—*Madeleine, Tricolore de Flandres.* **ROSE-COLOURED.**—*Charles Lawson, La Ville de Bruxelles, La Volupté, Paul Perras.* **DAK CRIMSON.**—*Boula de Nanteuil, Frederick II., Triomphe de Jussens.* **BLUSH.**—*W. Tell, Queen of Denmark.* **CRIMSON.**—*Paul Ricaut, Kean, Napoleon, D'Aguesseau, Chénédolé, Brennus.* **PINK.**—*Coupe d'Hébé, Charles Duval.* **PURE SLATE.**—*Schismaker, Moss Roses, Crimson, Laneii, Baronne de Wassenäer.*

OBSERVATIONS.—Have two sets of these. Cut back one set early, and do not remove them. Remove the other set later in the spring, and cut them back later. This will prolong the bloom. They are all hardy, beautiful, free, and abundant bloomers, and many of them quite distinct and as yet unmatched by autumnals. They will all make pole Roses if desired, and are equally good on the briar and Manetti. Those who give them up "commit (to use an expression of Talleyrand), a blunder worse than a crime."

AUTUMNAL ROSES.

WHITE.—*Acidalie, *Mrs. Bosanquet, Sombreuil, Mad. Alfred de Rougemont, Mad. Massot.* **ROSE-COLOURED.**—Anna de Diesbach, Anna Alexieff, Cecile de Chabrillant, John Hopper, Duchess of Sutherland, La Ville de St. Denis, Baronne Prevost, W. Griffiths, Louise Odier, *Reynolds Hole, Baron Gonella.* **BLUSH.**—Caroline de Sansal, *Souvenir de la Malmaison. **VERY DARK CRIMSON.**—Prince Camille de Rohan, Duc de Cazes, Vicomte Vigier, Lord Macaulay, Mrs. W. Paul, Alfred de Rougemont, Princesse Mathilde, and Richard Smith. **CRIMSON, RED, SCARLET, PURPLE, OR SHADES THEREOF.**—Charles Lefebvre, Sénateur Vaisse, Jules Margotin, Général Jacqueminot, Maréchal Vaillant, Triomphe de Paris, Géant des Batailles, Pauline Lanzezeur, President Lincoln, Peter Lawson, Madame Boutin, Mrs. C. Wood, Madame C. Joigneaux, *Madame Julie Daran, Professor Koch, Beauty of Waltham, Madame C. Crapelet, *Monsieur de Montigny, Eugène Appert, François Lacharme, Duchess of Norfolk, Souvenir de C. Montault, Madame L. Carrique, Mrs. Elliot, Pius IX. **YELLOW.**—Gloire de Dijon. For a South Wall.—Solfaterre, Triomphe de Rennes, Celine Forestier, Mlle. Aristide. **BUFF.**—Bourbon Queen.

The above are what I recommend. The following are magnificent and very hardy, but I cannot tell whether they would open in the north of England, Ireland, and Scotland:— Maurice Bernardin, Duc de Rohan, Auguste Mie, Souvenir de la Reine de l'Angleterre, General Washington, and Duchesse d'Orleans. Those with an asterisk had better be put near or close to a south wall. As regards the preceding six people must please themselves.

If you intend to have a large rosarium, the proper way to begin is to have 100 each of Jules Margottin, Senateur Vaisse, Cecile de Chabrilant, and Charles Lefebvre, and others in proportion. Instead of heaps of varieties, accumulate fewer and really good sorts. Subject to the observations made, I am sure that the persons for whom the selection is made could not make a disappointing collection.

One word to "Loch Ness." Acidalie is a very strong grower; Triomphe de Lyons and Dr. Brettonneau are bad growers; Celina is only fit to bud upon; Auguste Mie must be taken up annually, and have the roots cut back. In strong lands Manetti Roses should be root-pruned annually *in loco*, or be taken up and root-pruned. They will then give their flowers, and be less likely to run blind.—W. F. RADCLYFFE, Rushton.

SEEDLING MEDLARS.

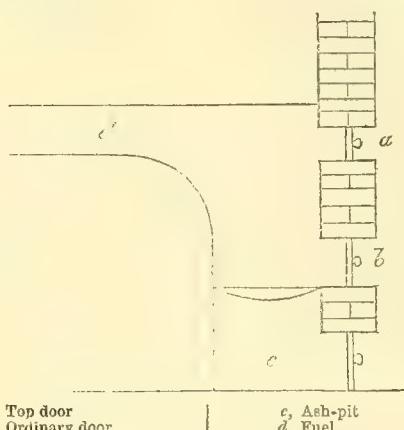

I SHOULD be glad to learn from some of your numerous readers if they have ever succeeded in raising Medlars from seed. I have often examined the stones, but have never been able to find any kernel in them; yet in spite of that I have sown them, and waited one or two years, hoping that a perfect seed or two might have escaped me, but no plant has ever made its appearance. I enclose a few seeds taken from the Nottingham Medlars, of a full size, and quite ripe. I confess to being quite at a loss to account for this kind of fruit, a native of our climate, not maturing its seeds.—MESPILUS.

[Gärtner says that the stones of the Medlar are one-celled, the cell containing two seeds, one usually abortive; the other is obovate, compressed, whitish, with a brown spot near the top. Miller says that if the seed be taken as soon as the fruit is ripe, and be sown the same autumn, the seedlings appear the following spring. We never tried thus to propagate the Medlar, and shall be obliged by any one informing us of their experience.—Eds.]

A VINYER FURNACE.

I AM about to give you a little of my experience, and in return, at the conclusion, ask a little of your advice. In April, 1864, I built a small vinery 17 feet wide and 22 long; a pit in the middle 4 feet wide and 10 long; flues round the pit, with an air space between them and the pit wall; the said air space coming over the flue at the hottest part from the outside, as mentioned in one part of the last volume of the Journal; all made as there stated, except that over the fire-grate the flame can rise up to the top of the flue; and opposite the flue end is a door, from which, down to the grate, may be 3 feet. I have an ash-pit door to regulate draught; there is also a furnace door at the proper place; the fire door is opened, and the fire made, in the usual way. When the fire has burnt up I close the proper fire door firmly, and open this at the flue end, and then fill the fire-box any depth with coke or cinders, which I can then regulate to burn any number of hours under twelve. I fancy the furnace heats economically, but as it has not been used in forcing I cannot as yet well affirm that this is the case. Now, between the pit and the front of the house is a border 4 feet wide, 3 feet deep, 1 foot stone and concrete, then soil from turves, mortar rubbish, and a few bones. In it were planted on May 17th seven Vines, their roots only covered 3 or 4 inches. No. 1 Vine, Black Hamburgh, grew 3 feet; wood ripe now, and leaves all off; but this is just at the end of the house. 2nd Vine, Black Hamburgh, only grew a foot; wood ripe, leaves off. 3rd Vine, Black Hamburgh, grew 7 feet; wood ripe, leaves yellow. 4th Vine, Muscat Hamburgh, grew 6 feet; wood ripe, leaves on. 5th Vine, Purple Constantia, 3 feet; wood

ripe, leaves partly off. 6th Vine, Bidwell's Seedling, grew 3 feet; leaves partly off, ripe all but the end. 7th Vine, Royal Muscadine, grew 8 feet; wood ripe, and leaves yellow.

All the Vines were 3 feet 6 inches apart except the Muscat Hamburgh, and it is planted close to a Black Hamburgh. Some of the Vines had half-inch wood when planted, the others three-eighths; of the new wood none exceeded three-eighths. Now what am I to do to these Vines—cut them down to two or three eyes? The front rods are 4 feet long, and all eyes are rubbed off, as the place is 4 feet 6 inches to rafter bottom, and the house is 15 feet high at back. Any further advice will be very acceptable to me, as I am a new beginner. Some of the eyes are very small, the others pretty prominent. I have Sanders on the Vine.

Will you tell me how to get a stock of bedding plants without obtaining too much from the nurseries, as that is expensive?—W. W., Northallerton.

[Your construction of furnace is excellent, and the top door for feeding the furnace must be a handy and a cleanly mode of feeding, besides acting on the slow-combustion principle. It is a move in the right direction. For the future good of the Vines we would cut them all back to two good eyes about the middle of December, and when they pushed select the strongest shoot, rubbing the other off. There must have been unaccountable reasons for the poor growths made; ours, planted in the eye, shot out to a length of 20 feet.

You do not say what kind of plants you wish to get a stock of, nor the kinds at present in hand; but if you give us the names of those you have we will tell you how to obtain a stock from them. Once you have the sorts there is no necessity to go to the nurseries except for new sorts, and to repair misfortunes.]

INTERRUPTION OF BOTTOM HEAT.

I HAVE just built a small stove, with two pipes for top heat all round, and two four-inch pipes under each bed for bottom heat. The pipes are in a chamber covered with slates, upon the slates are a few inches of broken bricks, &c., and then a bed of leaf mould, full of sticks and very rough, for about 18 inches in depth; in that I have plunged the pots, but I find I can get very little bottom heat, not nearly enough for propagating, and sometimes the soil even feels quite cold, and yet the top pipes are quite hot, and the temperature of the house is between 70° and 80°. Do you think any other material than leaf mould would be better? The leaf mould is also full of worms, woodlice, and many other insects. If I retain the leaf mould, how can I best get rid of the worms? Would tan or cocoa-nut refuse be better than the leaf mould in respect to letting the bottom heat penetrate? From the bottom pipes to the surface of mould is about 2 feet.—S. E. H.

[There is no doubt that your top pipes for heating the air of the house act efficiently. Have you felt the pipes in the chamber to see if they are equally hot? because if not, there is something to be done to secure a free circulation in

the chamber as well as in the exposed pipes. If these chamber-pipes are hot enough, then there is nothing wrong in the heating. These chamber-pipes will be most efficient in heating the slate if placed not far from it. If the pipes are hot, and yet the slate does not become so, open a few holes, say a couple of inches square, in the bottom of the chamber communicating with the air of the house, passage, &c. Lime or salt will destroy the worms in your leaf mould; the former will be the safest, as salt in excess would injure your plants and cuttings. Cocoa-nut refuse will save you from the worms, but it will be as bad a conductor of heat as the rough leaf mould, and if it become dry at the bottom will keep all the heat about the slates. Instead of this 18 inches of rough leaf mould, use some 5 or 6 inches of sand or roughish ashes, and if the slate becomes hot they too will be so. For all tender things, however, for which you require extra heat, you should have a glass hand-light, &c., to place over your cuttings, as that will keep the heat from radiating. From 80° to 90° will be high enough for the tenderest.]

ROSES BUDDED ON THE BLACKBERRY.

I HAVE tried this and the buds did not take (see page 456). I have budded Maurice Bernardin on the Sweet Briar this summer; it has taken and made wood.—W. F. RADCLYFFE, Rushton.

ROYAL HORTICULTURAL SOCIETY'S FRUIT, VEGETABLE, AND ROOT SHOW.

THIS, which was termed an "International Show," commenced on Wednesday last, and terminated, so far as perishable fruit and vegetables were concerned, on Saturday last; but the other objects will remain till the 16th. There were upwards of eighty classes in the schedule, but as no money prizes were offered—merely certificates bearing a money value according to the receipts—in many of the classes there was little and in some no competition. The Show, nevertheless, was a large one, and the display made by the Apples and Pears, of which it was principally composed, was very extensive and good, and served in some measure to compensate for the small quantity of hothouse fruit shown. Not only did they closely fill a range of tabling running almost the whole length of the conservatory, but they extended into both the adjoining arcades.

Though there were classes for collections of fruit from fruiterers and private growers, Messrs. Webber & Co., of Covent Garden, were the only English exhibitors. Their collection was well arranged for effect, and consisted of a noble Smooth-leaved Cayenne Pine Apple in the centre, two others of less size, two Black Jamaicas, and two Queens, Black Hamburg and Muscat Grapes, Prickly Pears, Tangerine Oranges, twelve splendid specimens of foreign-grown Uvedale's St. Germain Pears between 8 and 9 inches long and 6 in diameter, and weighing collectively 29½ lbs.; Catillac, Easter Beurré, and Glou Morceau, very fine; Reinette du Canada, Calville Blanche, and Gloria Mundi Apples, Pomme d'Api, Matthews' Eliza Pear, &c. The merit of this fine collection was recognised by a first-class certificate.

PINE APPLES were very poorly represented as regards numbers. By far the best were two noble Smooth-leaved Cayennes, from Mr. Ingram, gardener to Her Majesty at Frogmore, each weighing about 7½ lbs. A Black Antigua, of 3½ lbs., from Mr. Neale, Banbury, was second, and a Smooth Cayenne of 3 lbs. 12 ozs. from Mr. Wallis, Astle Park, third; a Black Prince, of 7 lbs. 6 ozs. coming also from the same. The best Queen was one of 3 lbs., from Mr. Heather, gardener to R. Pulford, Esq., Thames Ditton.

GRAPES were very good for the season, but the exhibitors were few. There were only two of White Grapes, Mr. Tillyard, Bentley Priory, who was first; and Mr. A. Ingram, Highgrove, Reading, second, both having large, regular bunches of Muscat of Alexandria, large in berry, and beautifully ripened. Of Black Hamburg, both in the class for six, and in that for three bunches, Messrs. Lane, of Berkhamstead, were first, with fine bunches, large in berry, and well coloured; and Mr. Hill, Keele Hall, whose name is a guarantee for the quality, second; Mr. Frisby, Sleaford, third. Bunches cut from the large Vine at Cumberland

Lodge, were again shown on this occasion by Mr. T. Ingram. In Any other Black kind, fine bunches of West's St. Peter's, from Mr. Tillyard, were first; and Barbarossa, from Messrs. Lane, second; Lady Downes', from Mr. Frisby, third. Messrs. Lane likewise exhibited fine baskets of Black Hamburg, Barbarossa, Black Prince, and Esperione, in the Miscellaneous Class.

PEARS, both of dessert and kitchen kinds, were unusually shown, and the former comprised many fine examples of Glou Morceau, Easter Beurré, Chaumontel, Beurré Rance, Passe Colmar, Winter Nelis, Vicar of Winkfield, &c.

For twelve dishes, Mr. T. Ingram was first, with Prince Albert, Chaumontel, fine and highly coloured, as indeed were most of the others in his collection; Easter Beurré, Shobden Court, Glou Morceau, Vicar of Winkfield, Knight's Monarch, Groom's Princess Royal, Jean de Witte, Winter Nelis, Moccas, and Passe Colmar. Mr. Cox, gardener to W. Wells, Esq., Redleaf, who was second, had likewise an excellent collection, the fruit set out upon Ivy leaves, and which comprised Baronne de Mello, Old Colmar, Joséphine de Malines, and others already named. Mr. Lumsden, gardener to Lady M. Hamilton, Sleaford, was third.

In the class for six dishes the competitors were more numerous. Mr. Tillyard was first with Chaumontel (finely coloured), Passe Colmar, Beurré de Rance, Glou Morceau (very large and fine), Easter Beurré, and Joséphine de Malines. Mr. Phillips, gardener to J. Barton, Esq., Pontefract, was second; Mr. Ford, gardener to W. Hubbard, Esq., Horsham, third. Several collections in this class were for various reasons disqualified, and among them one from L. Corbière, Esq., Cerisy Belle Etoile, Normandy, which contained fine examples of Uvedale's St. Germain, a kitchen Pear, under the name of Belle Angevine, Easter Beurré, very fine, but in duplicate, and Colmar des Invalides.

In three dishes Mr. Beasley, Twyford Abbey, Acton, was first with good fruit of Chaumontel, Glou Morceau, and Easter Beurré; Mr. Earley, Digsowell, second, and Mr. A. Ingram third. The best single dish was Glou Morceau, from Mr. Ford; and Beurré Diel, from Mr. Westbrook, was second.

The heaviest five came from Mr. Murray, gardener to the Rev. D. Williams, Tring Park. The kind was Glou Morceau, very large, but the weight was not stated; next came Chaumontel, from Mr. Plester, and, third, Glou Morceau, from Mr. Phillips.

In kitchen Pears the best single dish was Catillac, fine, from Mr. Ross, gardener to C. Eyre, Esq., Newbury; large and fine Uvedale's, from Mr. Scrymger, were second, and the same kind, from Mr. Cox, third. In no case did the weights of these dishes appear remarkable.

APPLES were very numerous, and in some of the collections very fine. For twelve dishes Mr. T. Ingram was first, having, amongst others, Blenheim Pippin, Gipsy King, an Apple of his own raising, a good keeper, and of excellent flavour; Court Pendu-Plat, Ribston Pippin, Claygate Pearmain, Rosemary Russet, Old and Scarlet Nonpareils, and Fearn's Pippin. This was a very fine collection, and many of the fruit were highly coloured. In the latter respect, however, those from Mr. Cox, of Redleaf, were the most remarkable; several of them were naturally high-coloured varieties, and, ripened in the fine climate of Kent, they were almost dazzling, and threw a ruddy glow around them. They consisted of Brabant Bellefleur, Col. Vaughan, Baddow Pippin, Golden Winter Pearmain, Ribston, Blenheim, and Cox's Orange Pippins, Scarlet Winter Pearmain, Sturmer Pippin, &c. This collection, and that from Mr. Betteridge, Milton Hill, Steventon, were equal third; excellent collections from Messrs. Lane, St. Mary's Cray, and Mr. Ford, being second. In six dishes Mr. Betteridge was first, Mr. Kaile second, and Messrs. Lane, St. Mary's Cray, third. In this class were shown fine examples of King of the Pippins, Court Pendu-Plat, Fearn's Pippin, Adams' Pearmain, Scarlet Nonpareil, Loan's Pearmain, and Spanish Pearmain, bearing considerable resemblance to the Blenheim Pippin, but stated to be distinct from that kind, being earlier and keeping longer. There were several other good exhibitions in this class. In three dishes Mr. Betteridge was first with King of the Pippins, and Blenheim and Ribston Pippins, of good size, and finely coloured; Mr. Ford second, with Golden Reinette, Blenheim and Herefordshire Pearmain; and Mr. Bentley and Mr. Kaile third. The best single dish for flavour was

Cox's Orange Pippin, from Mr. Hall, gardener to Captain Tyrrell, R.N., Acton; the same, from Mr. Plester, was second, and Blenheim, from Mr. Ford, third.

In kitchen Apples the exhibitions were numerous and good. The varieties consisted of Blenheim Pippin, Gloria Mundi, both of very large size, Alfriston, Mère de Ménage, Dumelow's Seedling, Yorkshire Greening, Waltham Abbey Seedling, Rymer, Bedfordshire Foundling, New Hawthornden, Glory of Kent, Beauty of Kent, and other approved sorts. For twelve dishes Mr. Betteridge was first, Mr. Cox second; for six, Mr. Betteridge first, and Mr. Parsons, Acton Green, second; for three, Mr. Ford first, and Mr. Betteridge second; and for a single dish, Mr. Plester first, with New Hawthornden; Mr. Wells second, with Blenheim, very large. The heaviest five Apples were Gloria Mundi, from Mr. Lumsden, Sleaford; Alfriston, from Mr. Young, Highgate, second.

MISCELLANEOUS FRUIT.—In this may be included a very extensive collection of Apples from Nova Scotia, which were also exhibited in competition with English growers. Among the sorts exhibited were excellent examples of Gravenstein, Ribston Pippin, Gloria Mundi, Emperor Alexander, King of the Pippins, Blenheim Pippin, Esopus and Flushing Spitzemberg, Red Baldwin, and other American sorts. Altogether the collection was such as did credit to the colony, and served to show that for Apples at least the climate is well suited. Mr. Hardie, gardener to the Viceroy of Egypt, was likewise an exhibitor, his collection being of a tropical character. It comprised Pomegranates of the largest size, two large bunches of Dates, which would have presented a better appearance had they not met with an accident on the journey; Citrons, Lemons, Shaddocks, various kinds of Oranges, Custard Apples, fruit of the Papaw tree, *Psidium pyrifera*, and Medlars. A large collection of Belgian Pears was likewise added to the Show on Friday, as well as a collection of fruit from M. Chevet, of the Palais Royal, Paris, comprising large specimens of Uvedale's St. Germain Pears, White Calville Apples, two large Capsicums, &c. Raby Castle Currants, in excellent condition, were shown by Mr. Ford, and Red and White Dutch by Mr. Tivey and Mr. Curd; the latter also showing Medlars and a Bromham Hall Melon. A good dish of Cuthill's Black Prince Strawberry was likewise exhibited, as well as some Quinces and Impératrice Plums.

VEGETABLES, ROOTS, &c.—Of these there was a tolerably large Show, and the articles exhibited were generally good. The best collection of Potatoes, comprising twenty-five sorts, came from Mr. Curd, gardener to M. Thoys, Esq., Reading. In it we noticed Webb's Imperial Kidney, Daintree's Earliest, Champion China (a pink-eyed sort) Fox's Seedling, Flukes, and Dalmahoy. Mr. Campbell, Winorick Hall, near Warrington, was second with Flukes, Scotch Dons, Arrowsmith's Seedling, Pink-eye Kemp's, Oxford Reds, and others, in all twenty sorts. For Kidneys Mr. Frisby, gardener to H. Chapman, Esq., Sleaford, was first with Brighton Albion, Jackson's Superb, Myatt's Superb, Early White Kidney, England's Glory, and Lapstone, the last very fine. A fine large kind, called Prince of Wales, was sent by Mr. Veitch; and Mr. Taylor, Hunton Bridge, had a fine dish of Huntingdon Kidney. In Round kinds Mr. Moffat, gardener to Viscount Maynard, Dunmow, was first with Pheasant's Eye, Painted Lady, Early Shaw, Early Tenweek, Transell's Seedling, and Dalmahoy, all sound and good. Mona's Pride, from Mr. Budd, was very good; and a tuber of a Scotch Potato, grown at Eccleshall, and weighing, when dug, $2\frac{1}{2}$ lbs., was exhibited by the Rev. C. P. Good. From Mr. Spyre, of Brighton, came 268 tubers, the produce of a single small white Potato, showing its extraordinary productivity. But as we are promised some remarks on this portion of the Show by our worthy correspondent, "UPWARDS AND ONWARDS," we will leave further remarks on the Potatoes in his hands.

Onions consisted of White Spanish, of which good examples were shown, James's Keeping, Silver Skinned, and Danvers' Yellow. Of Carrots Mr. Curd exhibited some of extraordinary circumference; and of Parsnips the Hollow-crowned and Student were well grown, clean, and of good size. In Beet, Pine Apple and Nutting's were the chief kinds; the latter, from Mr. Frisby, was first. In Turnips Mr. Ingram, Frogmore, and Mr. Ford, were first, White Stone, Orange Jelly, American Red-topped Stone, and Sutton's Early Six-

weeks being the chief kinds shown. Good roots of Salsify came from Messrs. Earley, Kaile, and Curd; and of Scorzonera from Messrs. Drewitt and Ross; and London Flag Leeks, of large size, from Mr. T. Ingram, Mr. Budd being second with Musselburgh. Chinese Yams, large and fine, and fine sticks of Horseradish, were shown by Mr. Tillyard; good roots of the former also coming from Mr. Cruickshank and Messrs. Sutton.

Of Peas there were only two exhibitors—viz., Mr. Frisby and Mr. Tivey; the former had *Ne Plus Ultra*, the latter Carpenter's Express. In Celery Wall's White Invincible and Ivory's Nonsuch from Mr. Hall were first in the White and Red classes; and of Endive, Green and White Curled, Moss Curled, and Batavian were shown by Messrs. Veitch, Frisby, and Earley. Of Cabbageworts excellent Savoys were shown by Mr. Budd; also by Messrs. Ingram and Frisby; and of Brussels Sprouts, those grown by Mr. Earley from home-saved seed were as fine as could be desired. Roseberry and Dalmeny Sprouts were also well represented. Of Cabbage the best was Early Dwarf York from Mr. Ford, and very good it was. Next came Fearnought, from Mr. Budd; and, third, Lochart's Rosette Coleworts, from Mr. Ingram, and which seem to have the property of forming a nice firm heart. Some good Broccoli was also shown by Messrs. Budd, Ford, and Frisby.

Of miscellaneous vegetables Cardoons, now seldom seen, came from Mr. Veitch; Mushrooms from Messrs. Moffat, Budd, and Ingram; Dwarf Kidney Beans and Telegraph Cucumbers from Mr. Mobbs; Asparagus from Mr. Curd; Sea-kale from Mr. Earley; and a handsome new *Lagenaria* from Natal was contributed by E. Stuart, Esq., of Nice.

In the same arcade with the vegetables Messrs. Sutton, of Reading, have a fine stand, extending 70 feet in length, the centre being formed by a glazed case, containing a thousand different kinds of seeds of grasses, forage plants, trees, shrubs, vegetables, annuals, &c. On each side of this centre are wings, in which examples of various grasses, large specimens of agricultural roots, and Gourds are exhibited; and the whole is tastefully decorated with Pampas Grass. There is also an interesting collection of Potatoes. Mr. Veitch likewise exhibited a collection of Potatoes, Parsnips, some remarkably fine Turnips, Swedes, and Mangolds, grass seeds, Chardon Cattle Potato, &c.

Lastly, preserved fruits and pickles were shown by Messrs. Fortnum & Mason, of Piccadilly, and Burgess & Son, Strand.

FLORAL COMMITTEE, DEC. 7.—On this occasion Mr. Veitch had a first-class certificate for *Manettia* species, a pretty twiner, with bright scarlet flowers; and E. J. Gray, Esq., Exeter, had a similar award for *Asplenium palmatum crispatum*, with crested fronds, and a very handsome variety. Three or four *Chrysanthemums* were also shown, but received no award.

FRUIT COMMITTEE.—A Sub-committee met at the Garden, South Kensington, on the occasion of the Great Fruit Show, to examine such new fruits as were exhibited. A seedling Pear, name Prince Consort, was received from the Rev. John Huyshe, of Clysthydon near, Exeter. It is a large and handsome Pear, in shape somewhat resembling a very large Marie Louise or Van Mons Léon le Clerc. One specimen was as much as 5 inches long and $3\frac{1}{4}$ inches wide. The skin is yellowish green; the flesh yellowish, firm, very juicy, and rich, with a sort of Gansel's Bergamot flavour. This received a first-class certificate. A seedling Pear was received from Mr. H. Muggleton, gardener to Hon. G. W. Milles, Lees Court, Faversham. It bore a close resemblance in shape to the Broompark, a seedling raised by Mr. T. A. Knight, but it was far inferior to that variety, and was not considered a desirable kind. Another seedling Pear was received from Mr. Matthews, of Clapham, under the name of Matthews' Eliza, which was recognised as being identical with Groom's Princess Royal, a variety raised and distributed many years ago by the late Mr. Groom, of Clapham. M. Grégoire, of Jodoigne in Belgium, sent a collection of seventy-one varieties of seedling Pears, not any of which were considered to possess any merit. One, intended as a compliment to the Assistant Secretary of the Society, was named Andrew Murray. It was coarse-grained, dry, harsh, acid, and peculiarly disagreeable, and the Committee were of opinion it could never be of any service. Mr. Thomas

Short, gardener, Clewer Park, Windsor, sent a seedling Melon, which for so late in the season possessed a great deal of merit. It was of large size and yellow. The flesh was of dark green colour and very well flavoured.

PRODUCE OF POTATOES.

In publishing the results of my experiments as to the comparative productiveness of Potatoes, in your Number of November 1st, my sole motive was to elicit from those who had made experiments, the results of their experience in such matters, and to induce others to make trials of various sorts of Potatoes for themselves. I was not weak enough to suppose that all the results of experiments made would agree with my own, because I am quite aware that the relative produce of everything, but especially, I think, of Potatoes, would depend much on climate, soil, &c., and in such a dry summer and autumn as our last on the quantity of moisture obtained, either from dews, or from partial showers. My object, therefore, is in some measure obtained by such information as "AGRICOLA" gives, but when he goes on to say that "some such mistake has insinuated itself into the Prescot experiments, seems certain from this, that the return claimed is altogether incredible," I must, in all courtesy, beg leave to say, that there is no mistake, and can be no mistake in the produce. The "proof of the pudding is in the eating."

I only obtained from Mr. Paterson 14 lbs. of seed of his Blue. That I did get from this seed 618 lbs. of marketable produce, is known to very many. About this there is no mistake, and the best proof I can offer to "AGRICOLA" is to say that should fate or fortune lead him to this neighbourhood, I should be very glad to show him about 600 lbs. of the sort which I have kept as seed for next year.

I may add that I do not know Mr. Paterson; that I have no personal interest in the matter at all; that I was only induced by a Scotch friend to give these new sorts a fair trial, and were I at home (which I am not), I would send for your inspection (Mr. Editor) Mr. Paterson's bill, proving that I only bought 14 lbs. of seed, which I again affirm produced 618 lbs. of Potatoes.—W. W. H., *Knowsley Cottage, Prescot.*

P.S.—Mr. Paterson will probably speak for himself, but, I think, he wrote me word, that some of his experiments on a larger scale had produced even more favourable results.

[There is no need for our correspondent to produce proofs, we have known him many years, and are able to say that his word is quite sufficient testimony to the truth of any fact within his own knowledge.

That Messrs. Paterson should have obtained at the rate of more than 1400 bushels per acre, intimates that an experiment on a small scale cannot be relied upon as evidence of the produce obtainable per acre, for we fear no Potato will yield 1400 bushels on that space. The first President of the Horticultural Society, the late Mr. Knight, tried many experiments on Potatoes, and he only has recorded his hope that 1000 bushels might be obtained.—Eds.]

SULPHUR v. RED SPIDER.

In Number of November 29th, a mixture of clay and sulphur is recommended as a paint for fruit trees. Does this act mechanically by smothering the insects? Last year, hoping to get rid of the unpleasant smell in Gishurst due to the chemically combined sulphur, I tried a number of mechanical mixtures of soap and sulphur on orchard-house trees, the proportion of sulphur being so large that the trees were quite yellow after painting. For a time I hoped that the washes had succeeded, but later on, red spider appeared active among the particles of sulphur. It would, therefore, seem that sulphur mechanically mixed has not the same effect as sulphur chemically combined, as in Gishurst.—G. W.

[It is quite true. We have seen red spider as merry as crickets among lumps of sulphur; but we have seen the same thing among dried Gishurst, and every other mixture that we have heard of or tried. We have more faith in the fumes of sulphur from a heated wall, or a hot-water plate,

than from any mere surface application, whether mechanical or chemical. When insects appear on the growing plant, Gishurst water and other mediums will be useful, and if the Gishurst is made with water a day previously, the unpleasant smell will be dissipated. For mere painting deciduous fruit trees, so as to smother up all insects' eggs, clay paint is as good as any, and that may be made of any colour with sulphur, soot, and lime, all of which ingredients are unpleasant to insects, though in their mere mechanical condition they will not kill them.—R. F.]

PYRAMID BEDS.

SOME time ago we were promised a description of the pyramid borders at Bentley Priory. As they were again alluded to last week as being very ornamental at Mr. Raikes Currie's new residence, I am induced to beg the favour of a detailed account of the mode of grouping, height, &c., at some convenient and early period. Is the Geranium Manglesii the same as Mangles' Variegated? if not, please describe it.—ESSEX.

[As soon as we can we will say a few words concerning Bentley Priory; and, were we to give all the details of the pyramidal beds, not borders, at once, we should only be spoiling the table by removing one of the best dishes. Last year an engraving was given of an avenue of pyramids at Putteridge Bury, and their planting in circles. These were very fair, but they were far behind the pyramids of Mr. Tillyard's at the Priory, which pyramids were of one thing and one colour. The beds at Putteridge, and perhaps at Mr. Raikes Currie's, were themselves considerably elevated. The mere beds at Bentley Priory are flat, the pyramidal appearance being given by the plants alone. The Calceolaria amplexicaulis and the Heliotropes were magnificent; but, like our old parish schoolmaster, we will not anticipate. Possessed of vast funds of knowledge, he particularly delighted in Rollin's History and Plutarch's Lives; and when, to whet our anxiety, he would give us an outline of the facts, and the philosophy of such a life, he would stop short with—"I must not anticipate!" In the meantime our correspondent may as well save a few old tallish plants if he can. It will require him some years to rival Mr. Tillyard.]

Geranium Manglesii and Mangles' Variegated are the same variety. This is generally used in combination; but, when well grown, a massive bed has a splendid effect, with its gossamer feathery-like flowers, which, with the light foliage, produce a charming effect. It is one of those plants, however, that do well in some places without any trouble, and will only do very middling in other places, do what you may.]

MANAGEMENT OF PEACH TREES IN POTS AND MAIDEN TREES.

SHOULD Peach trees in pots be taken out of the orchard-house after the fruit is gathered? My man has plunged mine under a wall in the open garden, and I find others are doing the same; but I see nothing about it in Mr. Rivers's book. Which do you consider right, to keep them all the year round under glass, or turn them out in the autumn? Also, when should they be brought back under glass again?

One more question I should like answered. I have bought about one hundred maiden Peach, Nectarine, and Apricot trees, which I am now having cut down and potted, but I have no room to put them in my orchard-house; but I have purchased a piece of ground where I intend building a residence, and hope to have a large orchard-house there. Now, I want to know whether I can keep these maiden trees (which are now being potted), for two years out of doors, so as to bring them to nice bearing trees by the time my orchard-house is ready, if so, is any particular treatment required? I am having them potted in 11-inch pots now, and thought I could shift them into a size larger next season, and the following season (two years' time), into still larger pots in which they would remain and be transferred to the orchard-house.—J. D.

[Such trees may either be set out of doors or kept in-doors with very good results. In a fine summer like the last, when

the fruit was gathered and the wood about ripe, the trees could be set out, the pots banked-up with litter, choosing as warm a place as possible in front of a wall to perfect the ripening of the wood until the leaves had fallen. After that it mattered little where the trees were placed, unless it was resolved to force them early, and in that case the north side of a wall, to rest the trees, and protecting the roots from extra wet, would be the best place for them. All others may remain in any place after the leaves fall, the pots protected from frost and wet, until the first frost of some 4° or 5°. This out-door treatment not only helps to swell the buds nicely, but also with the assistance of the little frost to get rid of the eggs and remains of insects. We have known plants left too long and much injured by the frost. On the whole then, as one of the chief objects of orchard-houses is the ripening of the wood, as well as the ripening of the fruit, and as the very dryness, easily secured, so much promotes the former, we generally keep our plants in-doors; but as soon as the leaves turn yellow and droop, we place the plants as thick as they will stand, protect the pots with litter, and use the rest of the bed of the house for other purposes. If we had a plant infested with insects, however, we would be apt to give it out-of-door treatment in the autumn.

Instead of cutting down your maiden plants now, we would merely shorten and prune back the side-shoots and pot in 9 or 10-inch pots. These pots should then be plunged into a bed out of doors, or into a shed all the winter, where they can have plenty of air. If out of doors a piece of board or tile should be placed over the pot to keep extra wet from the soil. During winter, if out of doors, extreme frost must be guarded against by protection, and a little tiffany or Nottingham netting, as a protection, will be necessary until the middle of May, so that the young wood may be healthy and kind. This, nipped during summer, as those in-doors, will secure a good foundation, and the chief thing will be to ripen the wood, so that the plants shall have all the sun possible, and little moisture in the autumn. Next winter they should be protected the same way.]

WELLINGTONIA GIGANTEA.

In some of your back Numbers this year, you furnished your readers with the dimensions of several of the large specimens of Wellingtonia now growing in different parts of England; and you requested that other correspondents would forward to you the size of their plants at the end of this summer's growth. I now venture to send you the dimensions of my plant, which was sent here by Mr. Barron, of Elvaston, in 1857, and was at that date 4½ feet high.

Our plant has upon it at this present time fifty-seven cones, each the size of a large walnut, and I think these will prove fertile, as the male and female blossoms were in perfection at the same time during the summer. The male blossom is pink in colour, and Mr. Barron expressed himself much pleased when he saw it and took some away with him, saying he should like to lay it before the members of the Royal Horticultural Society.

I have no hesitation in saying that our plant is as perfect a specimen as can be found in England. Other plants may, perhaps, be somewhat higher, but none can be more perfect in its pyramidal outline. It has not a twig out of place, and the triangle formed by its boughs from top to bottom is as correct as it is possible to conceive.

The circumference of the stem of this plant near the ground is 5 feet. The spread of the branches is 38 feet in circumference. The height of the plant is 15 feet 1 inch.—R. D., Monk Hopton, Salop.

ABSENCE OF COTTAGE GARDENING IN NORTH DERBYSHIRE.

If I had not been from home I should sooner have answered your query as to the reason of cottage gardening having made so little progress in North Derbyshire, at least as far as I am able to answer it.

The truth is there is no obvious reason. Various customs, manners, observances, are seen to prevail in some places, of

which it is difficult to understand how they arose, or why, having arisen, they were confined to those localities. But possibly climate may have had something to do with the neglect in question. Cottage gardening much prevails in Cheshire; but in Cheshire to all the old cottages you almost invariably find attached a small orchard filled with Apple, Pear, and Damson trees. It is almost certain that any one attaching a bit of land to a cottage for an orchard would devote a portion of it to a garden. In Derbyshire you see nothing of the sort, at least in the Peak—no doubt for this reason, that only the coarser fruits will ripen at all, and not those always. For instance: Walnuts grow well, but never harden the shell or produce a kernel; Filberts do badly, and will not always ripen. This severity of climate may have been such a drawback as to discourage instead of stimulate gardening, and cause owners to acquiesce in the idea that it is more profitable to keep the land in grass, for which it is admirable. Perhaps another reason might be suggested in the thinness of the population and fewness of the gentry to encourage such things in a large portion of the northern division of the country.

But whatever may be the reason of the fact, there is no doubt of it, as you observed. We are doing what we can to awaken a better taste by annual exhibitions, but it requires time to bring new habits into the country.—HUGH FORD BACON, Castleton, Derbyshire.

TRENTHAM BLACK GRAPE.

I THINK your correspondent Mr. G. Bester only read the last part of Mr. Pearson's article on the Trentham Black Grape, or he would never have asked, Has he grown it in a cool house? for Mr. Pearson distinctly says, "In one large orchard-house which covers 300 square yards, I planted a Vine to each of the pillars to see if good Grapes could be grown in Nottinghamshire without heat," and the result of that experiment has far exceeded Mr. Pearson's expectations.

I have not grown it myself, but I have had the pleasure of seeing it twice this year at Chilwell, both in heat and without heat, and in each house the Grapes were a credit to the grower, and would be so to any good Grape-grower. I can fully endorse all Mr. Pearson has said in its favour.

Perhaps your correspondent Mr. G. Bester treats his orchard-house the same as I once saw a beautiful glazed Peach wall treated—it was thrown open every day regardless of the weather. The consequence was small fruit, and not ripe until after that on the open wall.—T. D., near Newark.

IVY FOR EDGINGS.

I HAVE not seen the Ivy edgings in the gardens of the Emperor of the French alluded to by "K. M. P.", but many in our English gardens. The way they are made is to form the borders of old rubbish if the soil be wet, otherwise the plants will not withstand the winter, particularly when the more tender variegated kinds are grown. If the soil is light such precautions are not necessary. The plants being at hand—good strong plants, which are mostly raised in, or grown in, pots for a time—are planted out in spring 2 feet apart, watering them until they become established. As they grow the shoots are trained over the surface, and secured in the proper position by pegs. When the shoots meet, or the desired length is attained, they are pegged down, and the points directed towards a vacant space, ultimately there being none. When the surface is entirely covered, the points are cut off, and this makes the border dense in consequence of the number of shoots which arise from this stopping.

The after-management consists in keeping the shoots within their proper limits by going over them frequently, and cutting off those which are disposed to ramble, taking care to train such, if there be any vacant space to fill, in that direction instead of cutting them off, so that an equal surface may not only be obtained but preserved. It is also necessary to clear the border of dead leaves, as these are very unsightly if left to decay on the plants. Every three years or so the Ivy-borders should be cut quite close, leaving, however, a

number of shoots to furnish fresh growths and leaves to cover the surface quickly.

The best kinds for such purposes are the Algerian Ivy (*Hedera algeriensis*), *H. Roëgnériana*, and the different forms of *canariensis*; the Gold-blotched Irish, the Marble-leaved, and that known as the Irish palmate-lobed Ivy being very fine. The Slender-branched form of the *Hedera helix*, or *gracilis*, with those other forms of the species of small but close growth, are admirably adapted for training round the basket or wire-work of beds in the flower garden, where they have a fine effect: such are *H. helix Donerailense minor*, and its variety *marmo-rata*, *Cullis's Silver-margined, lobata, chrysocarpa, and pulchella*.

I shall shortly offer further remarks on these useful plants.—
G. ABBEY.

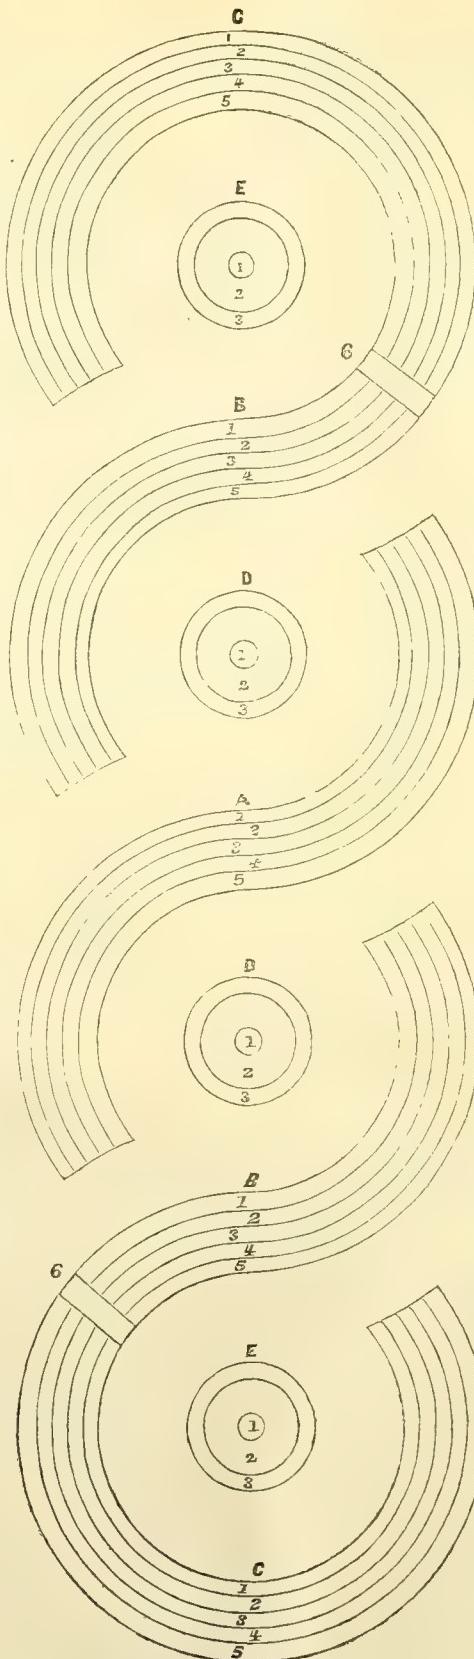

FLOWER-BORDER PLAN.

Will you give your opinion upon the arrangement I have made in the design which I enclose? It is situated in front of the drawing-room windows, immediately under the eye. My employer wishes to have it planted in the ribbon style.—
L. C. H.

[We think your proposed plan will look very beautiful, and your proposed planting cannot be improved on.

We think, however, your dividing your two side-borders by a band across of *Gnaphalium lanatum* will destroy the fine sweep of colour just by dividing it. We think that if you had your circles as now, and the centre broken border as now, and then mixed the outside row of the other two borders with *Koniga maritima*, and blue *Lobelia* all round, and the other lines the same all round, you would not have so much variety, but you would have a far more telling effect. It is a mistake to suppose that mere variety will produce grandeur of effect.]

- A. 1. *Verbena Purple King*.
2. *Geranium Christine*.
3. *Geranium Bijou*.
4. *Geranium Christine*.
5. *Verbena Purple King*.
- B. 1. *Koniga variegata*.
2. *Geranium Tom Thumb*.
3. *Calceolaria Aurea floribunda*.
4. *Geranium Tom Thumb*.
5. *Koniga variegata*.
6. *Gnaphalium lanatum*.
- C. 1. *Lobelia speciosa*.
2. *Geranium Flower of the Day*.
3. *Perilla nankinensis*.
4. *Geranium Flower of the Day*.
5. *Lobelia speciosa*.
- D. 1. *Humea elegans*.
2. *Coleus Verschaffeltii*.
3. *Centaurea candidissima*.
- E. 1. *Humea elegans*.
2. *Centaurea gymnocarpa*.
3. *Amaranthus melancholicus ruber*.

WHITLEY ABBEY.

THE SEAT OF LORD HOOD.

THE curiosity with which all strangers visiting Coventry regard the effigy of Peeping Tom induced me one fine morning in October to saunter forth from the "Red Lion" in quest of him, and, to my surprise, in a niche in the wall at the corner of the street facing the market-place was the veritable Tom in a field marshal's hat. How ridiculous! The general interest excited, even in remote parts of the kingdom, by the processions which occasionally take place at the great or show fair, and in which Lady Godiva occupies so prominent a situation, will plead my excuse for this passing notice.

On the right-hand side of the turnpike road to Whitley Abbey is the new cemetery, which was laid out under the superintendence of Sir Joseph Paxton, the member for Coventry. It comprises nearly eighteen acres. The ground selected for this purpose was exceedingly picturesque in its original state, and its beauties have been further enhanced by the masterly design, and the tasteful manner in which it is laid out. It is only of late years, and since the passing of the bill against intramural interments, that the English people have become, in some degree, familiarised with these picturesque and attractive places of burial, which have been at once the solace and the ornament of continental towns, affording not only a resting-place for the departed and a fitting retreat for sorrowing relatives and friends, but a promenade for the meditative, amidst gardens and alleys that speak of death, but tell their tale in a soothing spirit. It is only at a comparatively late period that we have permitted ourselves in this country any sympathy with those gentle and graceful cares and affecting symbols of lingering attachment which our continental neighbours have long since been accustomed to bestow upon the last dwelling-places of those they loved or respected in life. These testimonies of love beyond the grave—the carefully-tended flowers, the garlands of variously-coloured Everlastings, the handful of freshly-gathered flowers flung upon the tomb, the Snowdrops and Crocuses, in themselves the poetical symbols of "death in the midst of life," as they fade and die away, but no less emblems of a second life and resurrection as they spring forth again after the death of winter—all these graceful and touching evidences of sorrow seeking to find a

soothing vent in garnishing the place where the loved one awaits a second life, were long unknown among us.

Whitley Abbey is about two miles from Coventry. It is a spacious Elizabethan mansion of stone, situated on rising ground. It was here that Charles I. is said to have fixed his station, when, in 1642, he ineffectually summoned the city of Coventry to surrender. The stove and greenhouse attached to the south side of the house, as seen in the accompanying engraving, are 60 feet by 25, supported by pillars covered with *Mandevilla suaveolens*, *Ipomæa Learii*, *Passiflora Buonapartei*, *Bignonia venusta*, *Lophospermum scandens*, and other choice climbers, trained also beneath the roof from which they hang in rich garlands and festoons of flowers and foliage. Smith's Giant Scarlet Geranium covers a large space on the back trellis, and is 25 feet high; there are also magnificent specimens of Punch Geranium, Fuchsias, Camellias numerous and luxuriant, with their bright glossy leaves, and thickly set with bloom-buds, and Japan Lilies in full bloom, with fine healthy foliage. The Acacias are also worthy of notice for variety and good

cultivation. The fine *Gloxinias* also require favourable notice. In front are flower-beds on grass planted with the usual bedding-out plants—Scarlet Geraniums, Calceolarias, Verbenas, &c. Trained against the house, as seen in the engraving, are large specimens of the White Banksian Rose, Magnolias, and *Glycine sinensis*. In front of the lawn is the lake, and by a tasteful treatment of its boundaries considerable indefiniteness is obtained. At the head of the lake is a natural rockery, secluded, and approached from the pleasure-ground walk; it is composed of arches mantled with climbers, and narrow winding passages, steep and abrupt, canopied and darkened with evergreens. The crevices are filled with Ferns, seedling Azaleas and Rhododendrons, Orchis, Primroses, Foxgloves, and other and more rare sorts of British plants. The masses of Rhododendrons and hardy Azaleas with other shrubs of trailing habit on the rocky margin of the lake, which is varied by indentations and projections, must appear gorgeous in spring when covered with bloom and reflected in the water. The quiet character of the lake, its caverns, and its rockery, combine to make

WHITLEY ABBEY.

this place a scene of picturesque and artistic beauty. It is truly delightful to saunter through these lovely scenes with a mind capable of feeling the beauties and the glories of the creation, displayed in the insects climbing up the spiry grass or disporting on the fragrant flowers; in the scattered fish, of various colours, poised on tenuous fins; in the feathered inhabitants of the grove that make the welkin ring with their sweet music, and in the contrasted wonders of vegetable life, "from the Cedar that growtheth in Lebanon to the Hyssop that springeth out of the wall."

In the pleasure grounds are fine specimens of Evergreen Oaks, *Pinus excelsa*, Deodar Cedars, and other Coniferæ, planted by Colonel Hood, who was killed in the Crimean war, and on that account they give a hallowed and melancholy charm to the place.

The kitchen garden of three acres is some distance from the Abbey. It contains three vineries and a Peach-house, old-fashioned, but in good preservation, with strong healthy Vines and Peaches. The collection of Pears numbers as many as fifty sorts. They are to be seen against the walls, also as standards and dwarfs. One fruit of Léon le Clerc

weighed 12 ozs.; Louise Bonne of Jersey and Easter Beurre were very fine. Plums on dwarf bushes were bearing heavy crops, and the collection of Apples had that yellow, mellow, yet juicy appearance so agreeable to the eye and taste.

The park of 250 acres commands an agreeable prospect over some extent of country, and is adorned with some magnificent Beech and Oak trees; one of the latter measured 15 feet in circumference 3 feet from the ground. "Oaks," says Shenstone, "are in all respects the image of the manly character. As a brave man is not suddenly either elated by prosperity or depressed by adversity, so the Oak displays not its verdure on the sun's first approach, nor drops it on his departure: add to this its majestic appearance, the rough grandeur of its bark, and the wide protection of its branches. A large, spreading, aged Oak is, perhaps, the most venerable of all inanimate objects."

"Mark yonder Oaks, superior to the power
Of all the warring winds of heaven they rise,
And from the stormy promontory tower,
And toss their giant arms amid the skies.
While each assailing blast increase of strength supplies."

The Hon. Mrs. Hood has furnished her drawing-room with models of figures and groups in the various occupations common to each country, and which are generally copied from the *Illustrated London News*. The objects are distinguished for good taste and considerable skill.

"A thing of beauty is a joy for ever.
It's loveliness increases; it will never
Pass into nothingness; but still will keep
A bower quiet for us, and a sleep
Full of sweet dreams, and health, and quiet breathing."

The whole is under the excellent management of Mr. Pond, the head gardener.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PROCEED with former directions as regards manuring and trenching, which are the principal operations at this season. Gravel walks should come in for a share of attention. Sifted coal ashes are an excellent material for the back walks, as it bears the winter traffic well and is always pleasant to walk upon. A coating of this material may now be given if they are in a bad condition. Celery, take advantage of the first dry day that may occur if the ground is in a rather dry state, to earth-up closely any that may have outgrown the previous soiling, and be prepared to protect the ridges in case of severe frost. Dry stable litter answers very well for this purpose. Parsley, endeavour as far as circumstances will permit, to have a good supply under safe protection, for there is generally a large demand for this, and in the event of a severe winter it is difficult to save it by the ordinary protection of hoops and mats. Peas, sow a few more, and Beans, as succession crops, drawing earth to the strong of the first sowings. A little dry charred earth is excellent, laying it on each side of the stems. A few branching sticks or spruce fir will defend them from cold cutting winds or severe frost.

FRUIT GARDEN.

It is always desirable to have as much of the pruning and nailing done before the approach of spring as possible. Lose no opportunity, therefore, of forwarding the operations, for besides the advantage of having that kind of work done before the busy season, the garden will present a much neater appearance after the wall trees are nailed, the borders made trim, the small fruit-bearing bushes pruned, and the ground among them slightly forked over. See that the standard trees which have been recently moved or root-pruned are firmly secured against injury from winds, and also let any root-pruning or transplanting remaining to be done this season be executed as soon as possible.

FLOWER GARDEN.

The weather is still favourable for carrying out alterations and where these are in hand they should be prosecuted with the greatest possible dispatch. Planting and the removal of large trees or shrubs cannot be finished too soon, for it is of the utmost importance that the plants should be afforded some chance of making fresh roots before the trying winds of March. See to even small plants being secured against the wind, for these are often injured by being blown about after planting, which a small stake and a few minutes' work would prevent. Procure a stock of Briars for budding on next season. Let the roots be well trimmed, cutting back closely the strong ones, for these if left will be of little use save to furnish an endless supply of suckers. As soon as alterations are completed, and the beds and borders are put in proper order for the winter, let a little fresh gravel be put upon the walks if necessary, in order to render them firm and dry for the winter. Plants of a tender habit in the borders should have some litter, sawdust, or old tan spread pretty thickly over the roots, and a few spruce fir or furze bushes stuck round them. Creepers on walls or trellises should now be nailed or tied-in. Those of a tender description should be protected. Examine pillar and trellis Roses, and see if the soil wants removing, or the kinds changing. For choice sorts roomy holes should be made, capable of containing three or four barrowloads of well-prepared soil. Turfy loam of good quality is the chief ingredient, to this add a portion of rich rotten manure and, if at hand, a little sandy peat or leaf mould.

GREENHOUSE AND CONSERVATORY.

Chrysanthemums and most of the flowering stock will require frequent attention in watering. The leaves of Camellias, Oranges, &c., are liable to a dark scum: this should be cleaned away with a sponge at this period especially, as the chief interest among pot plants depends in a great measure on cleanliness, both with regard to the leaves and pots. Take care when frost arrives that the Heaths do not become too dry of a sudden. The best preventive of this is to be very shy in applying fire heat. We have already alluded to the ill effects of humidity and stagnant air in plant-houses as evils to be guarded against most particularly at this season, but these are of minor importance compared with one of our own creation, evidence of the existence of which is not unfrequently seen in the drawn and unhealthy occupants of greenhouses—we allude to heat, which judiciously applied, is, of course, of the first importance, but employed without judgment becomes a fertile cause of the evils above described. It must be borne in mind that a spring or summer temperature, without the sunlight of the one or the other, is altogether an anomalous state of things, and one which cannot be pursued consistently; with things so susceptible of such influences as plants, above all, high night temperature should be avoided. We are convinced of the value of the practice of employing night coverings, and of thus dispensing in a great measure with the use of fires.

STOVE.

Some of the early-ripened tall Cacti may now be introduced either in the stove or forcing-pit, and receive a liberal watering to commence with. Do not encourage any fresh growth at this period, rather aim at that kind of management which will serve to consolidate the growths already made and to develop the blossoms of the late-flowering plants in a proper way.

FORCING-PIT.

This is a capital period at which to introduce a considerable bulk of things for genuine forcing purposes. Rhododendrons, Azaleas, Persian Lilacs, Moss and Provence Roses, Sweet Briars, Honeysuckles, Kalmias, Daphnes, Rhodoras, the more advanced Hyacinths, Narcissus, Tulips, &c., may now be fairly started. A sweet bottom heat of 80°, and an atmospheric temperature of 65°, will be necessary, whatever the structure. One thing may be here observed, and that is—that it is in vain to introduce anything unless properly set for bloom. This points to the necessity of a special summer's training, as advised in proper season in this calendar.

PITS AND FRAMES.

Look over the plants carefully, at least once a-week, and remove decaying leaves, &c., which, when left, only encourage damp and mildew. See that the frames are well banked up, so as to be proof against any ordinary frost, and do not neglect covering up securely at night.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

CHOSE a dry day for wheeling a little rotten dung on to alleys, quarters, &c., to be used as wanted, reserving the chief of such work for dry frosty weather. Packed up Carrots, Beet, &c., in sand and dry earth in sheds. Protected Cauliflower, earthed-up Cabbages, and strewed the ground with dry burned rubbish, especially near the plants, which will alike protect them from severe frosts, and set slugs and snails adrift. If this fine mild weather continue much longer, we will just move up the most forward Cabbages intended for spring with the point of a steel fork so as to snap the extreme roots, and then fasten the earth firmly about them. This will check growth, and diminishing luxuriance will render the plants more sturdy for meeting a severe frost. Protected Artichokes with some litter round the crowns, which we find had been neglected. Cleared Asparagus ground of faded tops and weeds, and covered with a dressing of rotten hotbed dung, consisting chiefly of decayed leaves, the virtues of which will be washed to the roots by rains; but, as stated the other week, summer is the right time for helping the Asparagus.

Asparagus Forcing.—Gave plenty of air to Asparagus coming on in a common hotbed. We mentioned the other week that we had forced this vegetable in rather too large

quantities for our supply of plants for several years, and we mention it for recommending the practice of having good beds for forcing slightly, at least without the necessity of destroying the plants, which is generally the case when old roots are lifted and transferred to a mild hotbed. Last year we stated how such beds should be made so as to be forced by dung, by flues, or hot water; and how for a little help, a bed may have brick or board edgings, with a pit or narrow ditch round it in which fermenting material may be placed in March. No plan costs less trouble for present supply than lifting the roots, from four to seven years old, out of the beds, and forcing them in a slight hotbed; but then, of course, the roots are of no more use, and, therefore, a constant succession of young beds must be kept up to take the place of the older ones broken up. Thus treated we have had fine heads about Christmas from plants scarcely more than three years from the seed; but generally it is desirable to have the plants older.

One or two inquiries have been made as to the mode of planting such raised plants in the hotbed, and doubts have been expressed as to the possibility of gathering so many heads from such a small space. These doubts would be dissipated if it were recollect that all the good roots and buds were clustered close together, to yield as much as possible in the way of produce, without providing for the produce of another year. We treat these Asparagus plants in the hotbed just as some amateurs treat their one or two stools of Rhubarb in the open air—by slipping off every stalk and leaf that comes—a good plan for obtaining all the present produce possible, but not a good plan if we expect produce every year. Keeping in view, then, that we wish the bed for its space to hold as much as possible, and that by tree leaves, &c., we have a hotbed which will yield from 80° to 90° of bottom heat, we place all over it some 3 inches of sandy soil and leaf mould. We then begin at the end of a row or Asparagus-bed by taking out a trench, and with mattock, spade, and fork undermine the mop-like roots with their crowns, taking care not to break the latter. These will generally be all sound if the bed is young, but some will be rotten and decayed if the beds are old; and such should be removed, as without sound buds and roots there will be no produce. These roots are placed carefully in a barrow and are taken to the bed; and the first row of crowns is placed carefully at the back of the beds, and the long mop-like roots are drawn out in front of them and packed in the light rich soil. The next row of crowns is placed on the top of these roots as near to the first row of crowns as possible, and the mop-like roots drawn forward in a similar manner, and so on until the frame or bed is filled. A slight sprinkling of soil is then put over the roots, a watering given so as to wash in among the long roots, and then a couple of inches of leaf mould or old tan, or any light soil thrown over all. The crop will depend more on the previous treatment and the state of the crowns than on anything we can do to give strength to the plants after they are taken up. Extra heat is the greatest enemy they can meet with, and this can be greatly regulated by the air given. When once the shoots are about fit for use in winter, light and air are necessary for colour and flavour; but too much air must not be given in cold weather, or the shoots will be apt to be hard. Instead, therefore, of giving too much bottom heat, we prefer banking up the sides of the frame, so that we can give more air without greatly reducing the inside temperature.

Though we speak of hotbeds, however, our amateur brethren may have Asparagus all the winter, especially after Christmas, in their little greenhouses, or even in their rooms and windows. We have seen it very good in cellars—rather pale in colour, it is true, but much improved by being placed in damp sand for a few days before using, and set in a window, a little film being cut from the bottom of the shoot every morning. The damp sand is better than water. We have also grown it on the floor, and even by the sides and on the top of a flue in a greenhouse, beneath stages, &c., in boxes some 8 inches deep and a foot wide, moving the boxes to the light as the shoots rose some 3 or 4 inches above the ground. We have seen some such boxes very nice, in the window of a clergyman's study, after being forced near the kitchen fire.

It reminded us of the doings of another minister of the

gospel, whose kitchen was a regular forcing-house in winter for bulbs, Rhubarb, Sea-kale, &c. Enthusiast as he was in everything connected with gardening, these pursuits were engaged in, less from any object of mere self-gratification, than the—(well, it must have been self-gratification, too, though combined with)—the nobler desire, by means of a flower, or a vegetable out of season, to throw some ray of sunshine into the chambers of affliction and suffering. Owing, we suppose, to the influence of a more than mercurial warm-hearted kindness, every young girl in the kitchen, instead of grumbling at the trouble, took almost as much interest in the old barrels and tubs that cumbered her domain as her master himself. We have even been assured that the short instructive interviews on such occasions have become the beacon lights to regulate the course of a life journey. Such success, under difficulties, is just a proof of the truth of the old adage, that "Where there is a will there will be found a way."

Sea-kale and Rhubarb.—Took up some more roots, and placed them in the Mushroom-house. Here we have just taken a note out of the clergyman's book. When his Hyacinths and Tulips, and Narcissus, had filled their pots with roots in the dark cupboard, and begun to push at the top, he used to bring them nearer the fireplace, and, to encourage upright prolongation, place a pot of the same size, reversed, over them, with the small hole in the reversed pot open, except at night. This kept a higher temperature in the atmosphere round the lengthening flower-stem. When the covering-pot got in the way, the pot, with the bulb, was moved to the mantelpiece for a few days, and then to the window. Now, in the case of Sea-kale, we think the easiest and simplest of all plans for forcing it, is just to build a mild hotbed, that will yield about 80° of bottom heat, and from 55° to 60° of top heat, place the roots thickly in it, and cover with any old box or opaque material that will exclude light and air, and which will leave an open space of 12 or 15 inches over the crowns. For a constant supply for first cutting, this plan is apt to give too much produce at a time, and, therefore, it is more suited to large families and market supply, than to small households. In the latter case, little at a time and regularly is more wanted, and, therefore, though we might follow the above plan in a dark corner of the Mushroom-house, we prefer for the first crops, packing a lot of roots in some large pots. If these come faster than we want them, we can remove them to a cooler, dark place. If they do not come so soon as we want them, instead of placing more heat about the pots, which might injure the flavour of the vegetable, we find it better to place a pot of the same size reversed over them, and this soon draws the heads to the desired length. Let it be borne in mind, that all things thus grown in the dark, be it Sea-kale, Rhubarb, Chicory, or Turnip tops, depend chiefly for their strength on the stored-up matter of the previous season, and for their quality in being used in a comparatively short and stubby state—say 6 inches for Sea-kale, and 10 or 12 inches for Rhubarb. Go beyond that and you have watery juice instead of substance.

Mushrooms.—Perhaps it would be as well to notice what can only be defended in an emergency. A short time ago we stated that we feared our summer-beds would not give a large enough supply for a shooting party, and, therefore, we put more heat to the first bed in the shed Mushroom-house, by turning over a preparatory bed below the one that was to come on, so as to steam the house, and by letting heat into a hot-water pipe, and steaming the house by syringing the hot pipe. For eight or ten days the heat of the atmosphere would range from 60° to 65° and 70°, just from 5° to 10° too much for general purposes. The object so far was gained, as the bed has been, and is now, a white sheet of Mushrooms of all sizes, from that of the fashionable cap hat to the size of pin heads. But the very sight of the large thick Mushrooms tells the initiated that the thing has been over-done. We like to see those huge Mushrooms, when it is desirable to have them, clinging, as it were, to the bed, with their thick juicy stems only an inch or two in height. Those large specimens we are now gathering, on the contrary, are many of them on stems of from 3 to 4 inches in height—a sure sign that the bed has had too much heat, and almost as sure a sign that the produce may be ample for a time, but that it will be exhausted prematurely, and

that, therefore, when this treatment is from necessity resorted to, due care should be taken to secure successions. Even what we meant for a succession piece has come in a fortnight or three weeks too soon, and, therefore, a third piece has been spawned and earthed, and a fourth bit put in preparation. In making fresh pieces at this season in houses bearing for table, all rank steams should be avoided, or they will taint, and in some cases discolour the Mushrooms. The Mushroom itself is in no way particular as to the extra sweetness of the material at its roots, it is only as affecting the top that this care is necessary. In making a fresh bed, therefore, it is desirable to place the rankest material at bottom, and the sweetest at the top, and if this is not quite sufficient, the best remedy for keeping the house sweet by keeping down all noxious steams, is to cover the surface of the bed with a sprinkling, say an inch or more, of dry earth. This after having served its purpose, may be mixed with the manure at spawning time. At first from necessity, through shortness of manure, we used a considerable amount of dry, fibry loam mixed with the fermenting material, and for some time we do so from choice, as the soil becomes such a good preparer and moderator, that dung may be used without losing its rich properties by turning, drying, &c.

Trenching for Carrots.—The cleaning the pleasure grounds and the collecting of leaves has prevented us doing much in the way of digging, trenching, and ridging. Were we sure of a good frost in the month of November, we would prefer leaving such work until the surface of the ground were pretty well frozen, as that is one of our best helps for getting rid of many enemies in the shape of slugs and snails. It is as well not to delay after December, however, for if we wait for the surface to be frozen, we may lose the chance of having the fresh-turned-up ground pulverised and mellowed by the best of all cultivators. Bear in mind, that we disapprove of turning down frozen soil; but we do like to have the soil of beds and quarters frozen and thawed again before we turn it down. In all old kitchen gardens some extra care should be taken in preparing the soil for Carrots and other roots of a similar description. The great drawback is generally an excess of richness in the surface soil at least, which causes the roots to fork instead of descending straight and well-formed. This also is one reason why the Short Horn is more cultivated in such circumstances than the long Altrincham, &c. For a year or two, our Carrots did not please us, but this season they were very good notwithstanding the drought, and we believe just from preparing the ground as we used to do in old gardens. We have now commenced ridging a piece that has borne heavy crops of winter Onions, Peas between, and then Cauliflower between the Peas. The ground was, therefore, in far too rich a condition, especially near the surface, for Carrots. It is being ridged-up three spits deep, the upper spit being placed at bottom, and the fresh bright soil of the bottom, with just a little of the clayey subsoil, placed at the top. The bottom spits we will not meddle with any more, as they have been well broken; but the top spit, now in the form of ridges, we would scatter over with a little gas lime if we had it, failing that we will sprinkle a little tar with a brush over it, just leaving a drop here and there to deter by its smell; and after sprinkling a little lime, chalk, or lime rubbish, or charred rubbish along the rows, we will turn over these surface ridges several times during the winter before levelling them down for sowing in the spring, and the experience of the past would predicate that next season we shall obtain nice, large, straight roots, as the best richest soil at the bottom of the trench will entice them downwards instead of encouraging them to fork at the top. In very poor sandy soil we have seen magnificent crops from manuring heavily, but placing that manure from 12 to 15 inches from the surface.

Horseradish.—Few things keep up their price at market better than this hot customer. In general it receives but scant justice, being condemned to some out-of-the-way corner, and where, from remaining long in the same place, the produce becomes much harder and less succulent than younger, better-cultivated roots. We have met with some instances where due attention was paid to it, and it went through the rotation of cropping much the same as other perennial vegetables. In these cases the ground was duly prepared—not

little bits, in the usual way, but long thin pieces were used for planting, and the ground kept hoed and cleaned among the plants as regularly as among Cabbages or Onions. The result was fine massive bunches of underground stems. There was little difficulty with the old plantations, as, though the smallest bit of root-stem will grow, it will also lose its vitality like the dreaded *Convolvulus*, if the top is kept well cut with the hoe. The order of these plantations we felt to be a rebuke to some of our out-of-the-way corners. It is not a bad rule, in taking this crop, to keep an open trench; dig to the bottom of the root pretty well, and fresh plant as you go on. But we have always noticed that a man would require the eyes of Argus to do such work anything like systematically: and hence the Horseradish department as to appearance, is generally such that the least said of it the better. In making fresh plantations the ground should be trenched from 18 to 24 inches deep; in general little manure will be necessary, and that chiefly placed at the bottom; but if the ground is stiff, or approaching to clay, burned and charred rubbish, lime rubbish, and chalk will benefit it much, and cause the plants to grow with more vigour. The sets should be planted in rows, 20 inches apart, and 8 or 10 inches apart in the row. Where much in demand and valued, a little bit should be planted every two years or so, and the older plantation stubbed up.

Other departments next week.—R. F.

COVENT GARDEN MARKET.—DECEMBER 10.

The supply of out-door vegetables continues good. Forced vegetables only comprise Sea-kale and Dwarf Kidney Beans. Dessert Apples are still plentiful, and principally consist of Newtona Pippin, Cox's Orange Pippin, Nonpareil, and Old Golden Pippin. In dessert Pears the best are Winter Nelis, Glou Morceau, Chaumontel, Easter Beurré, and Matthews' Eliza, or Groom's Princess Royal, which is of good quality, and very serviceable at this period of the year. Grapes and Pines are sufficient for the demand.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

*CONIFER FOR DRY SANDY SOIL (*Monticola*).*—None will thrive so well in such a soil as *Pinus insignis*, and it is one of the most handsome.

BOOKS (J. T. P.).—“The Garden Manual,” which you can have free by post from our office for twenty postage stamps; and Richardson’s “Domestic Pigs,” which you can obtain from any bookseller.

NEW ORNAMENTAL-FOLIAGED PLANTS (K. D. T.).—Of the Mrs. Pollock class of Geraniums you might add to those you already possess, Captain Meade, Lady Cullum, and Sunset; also Saxifraga Fortuni, Lonicera aureo-reticulata, Iresina Herbetii, and Aucuba japonica picta. We might name a host of other plants did we know the purpose for which you require them, and whether you can command a stove temperature. You will, however, find a list of the new plants of the year in "Hogg's Gardeners' Year Book," about which you inquire. It is now ready, price 1s. free by post 1s. 2d.

GORSE OR FURZE PROPAGATING (Rusticus).—We find it succeeds better by sowing than transplanting, it being difficult to remove at any time, even when young.

PIONSETTIA PULCHERRIMA DYING (H. V.).—Your plant is dying from want of a suitable temperature. It is not usual for it to die down at this season, nor in fact at any time, though it does lose its leaves after flowering, when it should have a rest and be pruned in. It requires the heat of a stove, and cannot be grown, so far as we know, successfully in a temperature of less than 55° in winter, though we have had it doing fairly in a conservatory at about 50°. We fear it is dying back because the shoots were not sufficiently ripened, and you will only accelerate its death by cutting it back. Keep in the warmest and driest part of the house, and give no water beyond a little to prevent the wood shrivelling. If you have a hotbed ready in March we would plunge the pot in it, cutting down when the eyes became prominent, and growing in the frame hotbed all the summer, so as to have it in bloom early, which we fear will never be the case if grown in a greenhouse.

SHRUBS FOR GROWING UNDER TREES (Rusticus).—The best that we know are Berberis, or Mahonia aquifolium, B. repens, and B. Darwinii. They are very ornamental, and form excellent game cover. We have a plantation such as yours, which is desired to be ornamental, and we find that of all things we plant in it Aucuba japonica does the best, and takes to the situation better than any other plant. We have some plants 6 feet high, and as much through, and this under Elm trees which are large enough for roots to build in. Evergreen Privet does very fairly; so does the Box-leaved Privet; common Hollies, and common Laurels are indeed good plants for such places, but difficult to establish at first, owing to the dryness of such situations. We planted some hundreds last spring both of Laurels and Hollies, also Aucubas, and notwithstanding the unparalleled dryness of the summer, we have not lost a single Aucuba, and many Laurels which we thought dead are now shooting from the root; the Hollies are still alive, and will no doubt shoot with the return of spring. They were watered regularly twice a-week. It is no use planting such things in dry situations unless they are looked after until established. Common Yews we have done fairly, and Butcher's Broom well, Box does badly, Rhododendron ponticum middling,—the soil, however, does not suit such plants. Alexandrian Laurel (*Ruscus racemosus*) does well, Portugal Laurels are indifferent, and the Periwinkles are excellent for covering the ground. We have not had many opportunities of seeing Skimmia japonica in such situations, but feel justified from what we have heard in recommending it for select spots in shady plantations.

BIRMINGHAM FRUIT SHOW (W. M.C.P.).—Blenheim Orange and Blenheim Pippin are the same Apple, and the collection in which it was exhibited as two distinct varieties should have been disqualified. It was an oversight on the part of the judges. The letter you copied was not intended for publication.

EDUCATION OF GARDENERS (W. D.).—The subject needs no further advocating. You are quite right in considering a general knowledge of chemistry is desirable to be possessed by a gardener, and you will find chemistry fully applied to horticulture in "The Science and Practice of Gardening" published at our office.

OBTAINING A STOCK OF PURPLE KING VERBENA (P. J. A.).—If you have a gardener friend he would most likely be in a position to let you have the greater part of the cuttings desired by the beginning of next March. If you could obtain half, or even a fourth of them, by the first week in that month, you might have a hotbed of well-sweetened dung made a fortnight previously, 5 feet high at back, and 4 feet in front, and a foot wider than the frame all round. This would give a bottom heat of from 80° to 85°, and a temperature of from 70° to 75° within the frame. A few inches of rather dry soil should be placed over the bed, and 2 or 3 inches of moist sand upon it. The cuttings, being inserted in pure silver sand, in saucers, without drainage openings, will, if the soil be kept wet, strike in ten days or a fortnight. You may then place some rather light loam and leaf mould within the frame for a few days, to become warm, and in this the cuttings may be potted singly in 60-sized pots when well rooted, watering gently with water of the temperature of the frame. Continue them in the frame, and when sufficiently grown take off their tops, and make cuttings of these, the bed being lined to keep up a temperature of 60° or 65° at night. These cuttings will strike in another ten days or a fortnight, and be ready for potting off, and in about ten days more they will each furnish a cutting from the point. The cuttings from which they were taken in the first instance will, through the stopping, by this time have made two, three, or more shoots, now of sufficient length for cuttings, which, with those already struck, will give you something like the number of cuttings desired, and of course plants by the latter part of April; but you must so time a bed as to have it ready for the third lot of cuttings by the third week in April, the two first batches being gradually hardened off. The last batch will be struck in ten days or so, when they are to be potted off, and, when well established, gradually hardened off, so as to bear planting out in the last week in May. Providing you cannot obtain one-fourth of the number of cuttings desired by the beginning of March, we would purchase, if we could, a dozen strong plants (which we very much question if we could do), and place them in a mild hotbed, not so hot as for cuttings; and having other beds ready to strike the cuttings in as they are obtainable, twelve good plants would furnish the number of cuttings you require; but we fear the main difficulty will not be in obtaining the cuttings, but the plants to take them from. Your best plan would be to make friends with some gardener who has these plants to furnish by the thousand. Failing this, we do not think you could do better than purchase a few dozen strong plants early in spring, even if you gave for them a trifile more than the regular price.

CINERARIA LEAVES CURLING (J. P. F.).—If your Cinerarias are free from why do you smoke them once a-week? We have no evidence, but think that most likely the curl in the leaf is from the frequent use of the tobacco smoke, and letting it reach the plants in a hot state.

ADDRESS (H. J. V. H.).—We have not Mr. Noye's address.

CALADIUM—COBEA SCANDENS—GLOXINIAS (*Rosa-flora*).—We fear the Caladiums will perish if kept in a greenhouse during the winter. They should be wintered in a stove, and be kept on a damp floor, so that the soil may be kept a little moist. If kept dry the roots are liable to rot when they are watered in the spring. If you have no better place than a greenhouse, you will make the most of it by keeping them in the hottest part, and not letting the soil become too dry. If the case was heated they ought to have been kept in it without water all winter. Pot them in March, and put them in the case at once, watering sparingly until growth fairly commences, then water freely. Cobea scandens does not flower because it has not room enough on a small wire trellis. Give the plants large pots to grow in, and the upper part of a back trellis in the greenhouse, and they will bloom abundantly; or, if you want anything to cover the roof in order to afford a little shade to Ferns and the like, your two plants will cover them in a short time. You will do no good by cutting them down until they become unsightly, when the cutting back will induce fresh shoots with finer foliage. Give the Gloxinias very little water and keep near the glass, and they will go to rest as soon as they ought. Keep in the warmest part of the greenhouse all winter, placing the pots on a damp floor, but without any water. Shift in March from thumb pots into 24s, watering gently; and do not water much, only keep the soil just moist until they begin to grow. If you have a hotbed to plunge them in after potting they will do all the better, and you may grow them in it until they are showing for bloom, when they will do well in the warmest part of the greenhouse if they are hardened-off a little before removing them from the hotbed.

COVERING ASPARAGUS-BEDS IN WINTER (H. N. E.).—Unless you wish to have the Asparagus with a long slender underground shoot with no more of it eatable than the green or purple tips, there is no benefit in the French system which you mention. In what way the uncovering of the roots in winter can benefit the plants we cannot perceive; and we know very well if the soil were taken off the crowns in autumn that the frost would kill every crown so exposed in winter, for Asparagus, though a native of this country, becomes very tender through high feeding or rich manuring. The crowns in winter ought not to be covered with less than from 3 to 6 inches of soil, 3 inches more of manure being added every autumn. It should not be too rotten, so that it may act as a manure and protection at the same time. Taking the roughest of this away in March, and forked the shortest into the beds at the same time, is the best method of securing strong shoots in April onwards. These are not fit for cutting until they are from 3 to 6 inches out of the ground, or more than half green or purple, that part only having the flavour of Asparagus, the underground white part being about as tough, and quite as tasteless, as the root of an Elm tree. This is the English system, and the same as that pursued by your gardener. Year-old plants are not covered with soil or anything in autumn, for, not being highly fed, they are not so tender as old plants. The French system differs from the English in earthing the beds in spring, so that the shoots may be blanched their full length, or to a length of 9 inches with the tips just coloured. Such look very nice, but are tasteless. The beds being covered with soil in spring it is necessary to take a quantity of it off in autumn, so as to prevent the roots or crowns rotting, as they are liable to do when in a wet soil, and in order that the roots may be better manured, and not to expose them to the atmosphere, for that can do plants little good when they are in a state of rest. In this case the soil requisite to blanch the shoots would have to be put on the beds again in spring. There certainly would be no harm in trying the French method; but if you wish good Asparagus for table keep to the old plan.—G. A.

STENCH IN GREENHOUSE (Erin-go-bragh).—Without more particulars we cannot account, with certainty, for the bad smell from your flue. If newly done the lime would give off strong vapours when a strong fire was used. In such a case you had better use a slow fire all day during the mild weather, with plenty of air in the greenhouse, until the bricks and joints are slowly dried. Are you sure that clean water was used for making the lime, and also that the bricks were sound and good? for we recollect of a flue being made with bricks from what had been a manure tank, and no time would remove the smell. In either of these cases much more care and patience must be used. Does the flue draw freely? for if not the smoke will be apt to come through the joints; and if rubbish, such as cinders, containing bits of cloth, feathers, vegetables, &c., is used, if the smoke do not come through the odours will. Is your iron pipe for the smoke large enough for the flue, or if large is it clear throughout? as they soon fill, and the scent from themselves, and then from sending smoke back, is bad. Use, at first, good dry fuel.

HOT-WATER PIPES FOR CUCUMBER-HOUSE (Wigan).—You do not state the height of your 8 feet wide and 23 feet long span-roofed Cucumber-house, with a bed 2 feet 3 inches wide on each side; but allowing it to be of the ordinary height, we would say that one pipe all round below the beds would be sufficient for Cucumbers in May. To get Cucumbers all the winter, or very early, you had better have two pipes for bottom heat beneath each bed, and two for top heat all round.

HEATING BY GAS (G. P. S.).—We should be glad if some experienced correspondents would state their practice as to this mode of heating. We adopted it some years ago successfully. Meanwhile we would state that few plants suffer more from gas fumes than Ferns do, and, therefore, the fumes should be kept out of the house by having a tube or chimney to pass into the outer air. Could not the house be heated from the same place as that which is used for the greenhouse? If the results of the combustion of the gas are got rid of, we have no doubt that gas would serve the purpose.

CELERI BOLTING (Bickley).—We presume you mean that your Celery is throwing up the flower-stalk, and therefore becoming unfit to send to table. You would find lately the whole *rationale* of this in an article by Mr. Fish. Dryness at the roots is the chief cause, and the next cause is checking growth before planting out.

TUBEROSE CULTURE (Jane).—We fear no better results will attend your efforts another year, as the roots seem to be considerably weakened. We would pot them in March in turfy loam of a rather strong nature, giving only a slight watering, and keeping on a shelf in the greenhouse. In April plunge the pots in a mild hotbed (75°), and keep them there until the first week in August, giving a good supply of water, and syringing the plants overhead, so as to keep down attacks of red spider. They should be kept near the glass. When they have made all the growth they appear disposed to do reduce the supply of water to half for three weeks, and in three weeks more leave it off. During the winter keep the pots in a light airy part of the greenhouse.

BOILERS WITHOUT BRICKWORK (S. T.).—Any of those boilers advertised as suitable without setting in brick would answer your purpose, providing you have a chimney from them. If the boiler is inside the house no heat will be lost, but great care must be taken of the fire to prevent back draughts, or you will have the fumes that the flue now gives you. The advantage of a boiler, with or without hot-water pipes attached, is that the sides do not get so hot as an iron stove carelessly managed is apt to do. For all small single greenhouses for amateurs we would prefer a brick stove to an iron one, because the brick does not get so hot, and retains the heat longer than the iron.

EARLY VINEY (A. B. C.).—Your proposed house will do admirably for early forcing, or for keeping Vines late; but for the purpose you should have three pipes instead of two for your hot-air chamber, and you will want at least double the pipes you propose for top heat.

BOOK (G. L. D.).—“The Cottage Gardeners’ Dictionary” defines the names of the plants. It is published by Mr. H. Bohm, London.

TREE ONION.—“A Nurseryman” wishes to be informed where he can obtain this species? He has applied without success to other nurserymen.

FILBEET AND COB NUTS (S. T.).—Most likely the variety advertised in our columns is an improvement on former ones, but whether it be the one you speak of or not, we are notable to say. In our columns next week, you will see an article on the Filbert by one of our correspondents, which will give the information you require.

RASPBERRY CANES NOT BEARING (M. B.).—If your situation be a very dry one, this fruit will not do well with you, but if you can remove them to a damper one, so much the better. After planting cover with rough dung, and in future years dig only very shallow amongst them, as the roots lie near the surface. Mulching in summer and supplying with liquid manure will do much to insure good fruit even on dry ground. If the plants be vigorous, you may leave four or five canes, provided the plants be wide enough apart, but do not by any means crowd them. Is your kind a good one? if not, try Prince of Wales, or Improved Fastolff.

REMOVING GOOSEBERRY, CURRENT, AND OTHER TREES (Idem).—These may be removed as early as you like, taking care in doing so not to tread the ground into a sort of putty-like mass. The earlier such work is done after the leaf falls the better, in order that the roots may commence their work in their new abode.

CINERARIAS NOT FLOWERING IN LARGE POTS (Idem).—It is quite as well that your plants do not show flower-stems, as it is likely these would all become abortive or nearly so, and produce no petals, as is generally the case with Cinerarias showing flower in the dark days. By-and-by your plants will be all the finer from not throwing up flower-stems too soon. If you can induce them to flower in October that will do, but not later.

PRUNING PEACH TREES (J. H.).—It is customary to shorten the shoots in all cases where a good wood-bud can be had to cut back to. Usually such buds are between two bloom-buds, but care must be taken to insure this, and it is better to delay the pruning until these show themselves with certainty. If there be plenty of wood well furnished with bloom-buds on the tree, you may cut away the gross shoots entirely, unless one should happen to be where it is wanted to furnish a naked part of the tree. It is, however, sometimes necessary to leave shoots their full length when trees are not furnished with wood-buds, and this is often the case in trees not over-healthy, as there is generally one or more buds at the point which are certain to grow. We must also caution you against leaving fruit on a branch that has not a leading shoot, for although the blossom will set and the fruit will advance to a considerable size on such shoots, it will not arrive at maturity, and will, therefore, only exhaust the tree and cause disappointment.

GRAPE FOR LATE VINEY—ROUND AND LONG BEDS ALTERNATELY (B. H. W.).—Black Alicante is suited for a late viney, but is a bad settler. You had better have Lady Downes’. We forgot the exact size of the beds at the Crystal Palace, but whatever the diameter of your circle may be, the same width and double the diameter in length will look very well for your long beds. Thus, if your circles are 8 or 10 feet in diameter, the long beds should be 8 or 10 feet wide, and 16 or 20 feet in length. Of course, the sweep of the circle will cause the rounding-in of the ends of the long beds. It does not matter whether the outside end of a long bed is rounded or not, but it would look as well done so, and to give a reason for doing so, you might place a small shrub or Rose on the grass there. It is, however, a matter of no moment. The white Geranium will not be so showy as the Feverfew early in the season, but it will likely be better in the autumn. We think the long beds will be best planted in lines with a border all round. But you may change them every year, and cross and recross them in ever so many plans, and all be beautiful if symmetrical and the colours bright and distinct.

NAMES OF FRUITS (Inquirer).—Vicar of Winkfield. (T. M. F.).—Calville Rouge Apple; Van Mons Léon le Clerc Pear. (William Hilder).—1, Blenheim Pippin; 2, Early Nonpareil; 3, Bedfordshire Foundling; 4, Scarlet Nonpareil. (George Curd).—1, Fearn’s Pippin; 2, Court of Wick; 3, Like Colonel Vaughan’s; 5, Calville Blanche; 7, Old Nonpareil; 8, Franklin’s Golden Pippin; 9, Golden Russet. (J. A., Nottingham).—It is one of the wine Grapes, and probably never had any name known in this country. It is quite worthless.

NAMES OF PLANTS (C. S. N.).—Barren frond of Adiantum capillus-Veneris, Common Maiden-hair.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PREVENTING THE RAID'S OF FOWLS— BRAHMA POOTRAS.

THERE are one or two plans by which “A SOUTH COUNTRYMAN” might, I fancy, still keep his special pets, Hamburghs. True, they are terrible fliers, but it must be remembered that all fowls fly only when alarmed, and that their method of “fencing” is to alight on the fence like a

Welsh hunting pony, and then down on the other side. Now, if the present fences of “A SOUTH COUNTRYMAN” are walls, he may nail stout strips of wood on his yard-side of the wall firmly into it, letting them be 2 feet at the least higher than the wall, and about 6 feet apart. To these let him attach some fine three-inch galvanised wire-netting, and if he do not put a connecting rail between his uprights, as so many do for the sake of appearance, I do not think even his Hamburghs will get over. With a connecting rail they will be certain to make it the alighting spot. In addition to this he may cut half of one wing, and if he is careful to do this himself, cutting only the under wing, no person can detect it, and it materially diminishes the power of flight. If the fences are wooden the same plan may be adopted. A hedge fence must depend on its goodness, but a foot width of wire at the bottom, if the fowls can get through, and a modification of the uprights and wire at the top ought to succeed. In the case of hedge fences the wire must be wider at the top; but “WILTSHIRE RECTOR’S” advice to another correspondent in the same Number will suit him. “Try, try, try again,” and from my own experience I feel certain he will succeed.

I have to thank several of your correspondents for kindly notices of any communications, and I am very glad to see from “BRAHMA POOTRA’S” account, that my history of Lord Tredegar’s Show is bearing fruit.

I hardly know how to take myself in reverse—to wit, “Z. A. B. Y.” “T”is hard work to write the letters that way,” and, as Sam Slick would say, “don’t seem to come kinder natteral.” Does he mean all he says? or is he, as the same author would say, only “a bannering of me?” Well, it is more suited to my *amour propre*, bump very largely developed, that it should be the first; but I may tell him, that “the idea of the judge giving an account of his awards” is not mine, but I either read in your report of the Poultry Club October Meeting, or dreamt that I did, to this effect, that in cases where the judge appeared to have given the prizes in opposition to the standard of excellence, he would be requested to explain his reasons for so doing, and I still think that from such exposition made public all of us would learn something.

I do not know whether “Z. A. B. Y.” fancied I was the writer under other feathers of the said article, in defence of the purity of my pets (Brahmas), signed “B.” if so, he will shortly find out his mistake; at any rate I think he will see at Birmingham, that although the correspondent might have been buried with the Brahmias, his proposed tablet erected and all, that somehow the Brahmias themselves have survived the burial and have mustered more strongly than ever, and that numbers will call them remarkably handsome birds.—Y. B. A. Z.

DARLINGTON EXHIBITION OF POULTRY AND PIGEONS.

THIS was the twelfth annual meeting held under the management of the Darlington Committee, and it is most satisfactory to say a better Show need not take place, even in the most favoured locality. The popularity of the meeting just closed may be estimated from the fact that not only were to be found in the catalogue the names of most of the principal English breeders, but also the Show was greatly improved by a very spirited competition from noted breeders resident in Scotland, and even the Emerald Isle. The very liberal list of prizes, therefore, offered at Darlington carries conviction that, with a good amount of premiums, a first-rate competition may invariably be insured.

The arrangement of the pens was excellent, and the most careful attention was devoted to the specimens whilst publicly exhibited. The total number of pens shown was somewhat over seven hundred, and the amount of inferior specimens was remarkably few.

In Spanish fowls Viscountess Holmesdale took precedence in adults, and Mr. Brown, of Sheffield, in chickens, the cup being secured by the adult birds, though the chickens ran closely for this much-coveted honour.

In Grey Dorkings the show was most meritorious, and, perhaps, the rivalry was even greater in these classes than any other throughout the Show. As may be generally supposed,

Viscountess Holmesdale made a very large and superior display of these useful birds. This lady's first-prize pen of old birds added most materially to the high reputation of the strain of Dorkings, for which Linton Park is now so proverbial. They gained the first prize in their particular class, an extra prize of a silver cup for the best pen of Grey Dorkings exhibited, and the yet additional trophy of the Society's principal silver cup for the best pen of poultry in the Exhibition, all breeds competing. Of course the neighbourhood of this particular pen seemed a perfect "resting-place" for all visitors, and at times it was even difficult to obtain a furtive glance, the anxiety to get a sight of them being universal. In chickens Mr. Charles Priest, the well-known manager of the poultry belonging to the Marchioness of Bath, stood in the first position with some capital birds that were equally successful at Brighton the previous week, and seemed but little the worse of their long journey. The first-prize Single Grey Dorking Cock was the rosy-combed one that has been oftentimes equally successful in other years, the property of Lady Holmesdale. Mr. John Robinson, of Vale House, had it all his own way in White Dorkings with a very superior collection.

In *Cochins* the success was almost a counterpart of that at the late Birmingham meeting, Capt. Heaton taking the cup, pressed closely by Mr. Bates, of Birmingham, Mr. Stretch, of Ormskirk, and one or two others. The White Cochins were really good, and shown in first-rate condition.

In *Brahmas* Mr. Boyle, of Poyner Park, Dundrum, Dublin, left but a very sorry lot of premiums to the share of his rivals, winning in both classes (old and chickens), and again for Single Cocks, though the competition was excellent, and the classes well filled.

The Game were all of high character, and Messrs. Statter, Fletcher, Aykroyd, Julian, Sir George Gore, Billing, Crossland, and a few others found a host of opposition from Game fowls of the best strains in the kingdom arrayed against them, so that to win their position was no slight undertaking.

In *Hamburghs* the Spangled birds were beyond doubt the best represented variety—a feature we scarcely anticipated in so generally well-known classes, particularly as the Pencilled breeds abound in the surrounding districts.

The Polands were exceedingly good, the Black with White Crests being especially so.

We regret, as faithful journalists, to be compelled again to record a fresh attempt at deception practised by the owner of decidedly the best pen shown in this class, and which discovery not only entailed the loss of a first prize they would otherwise have obtained, but the well-merited disgrace of public "disqualification" also. It really appears as though, to some minds, the annoyance of detection exercised but little salutary influence in such matters; for it is only, perhaps, six months back that the same exhibitor, Mr. Henry Carter, of Upperthong, Holmfirth, met with similar exposure for then dyeing the tail of a Poland cock; the imposition on the present occasion being adopting a similar plan as regards the legs of the fowls he exhibited. It is well known to all experienced breeders that the legs of Black Polands fade much in colour from age, still this fact affords no justification for adopting measures to secure prizes quite opposed to all regulations, and equally so to the opinions of all straightforward competitors. In the hope to put down such unjust practices, as they affect other exhibitors' interests, we adopt the plan of exposing to public animadversion every case that may be capable of proof; and though an occasional ill-gotten prize may possibly be secured by such malpractices, the risk of disgrace may, we trust, even yet prove a deterrent for the future.

The Silver and Gold-spangled Polands were better than customary; and most of the Bantams were exceedingly good.

Geese, Turkeys, and Ducks were shown of the best quality.

The show of *Pigeons* was capital throughout, though the entries were somewhat less extensive than heretofore. The Carriers, Powlers Fantails, Barbs, and Jacobins are worthy of especial mention.

SPANISH (Black).—First and Cup, Viscountess Holmesdale, Linton Park. Second, E. Brown, Sheffield. Commended, Mrs. Bolland, Bedale. *Chickens*.—First, E. Brown, Sheffield. Second, D. Parsley, Bristol. Third, J. Shortose, Newcastle-on-Tyne.

SPANISH (Black).—*Cock*.—First, H. C. Nobbs, Northampton. Second, E. Brown, Sheffield. Highly Commended, Viscountess Holmesdale. Commended, D. Parsley, Bristol.

DORKINGS (Coloured).—First and Cup, Viscountess Holmesdale. Second, T. Statter, Whitfield, Manchester. Highly Commended, F. Pease, Southend, Darlington; Rev. J. F. Newton, Kirby, Stokesley; Miss Forster, Cliffe, Piercbridge. Commended, Lord Binning, Mellerstain, Kelso, N.B.; Miss Milne, Otterburn, Kelso, N.B.; A. Perkins, Darlington. *Chickens*.—First, C. Priest, Worthing. Second, F. Pease. Third, Sir St. G. Gore, Hopton Hall. Highly Commended, Viscountess Holmesdale; Rev. J. G. A. Baker, Biggleswade. Commended, J. White, Northallerton; Rev. J. F. Newton; Viscountess Holmesdale; J. Robinson, Garstang; Sir J. D. Wauchope, Bart., Dalkeith, N.B.

DORKINGS (Coloured).—*Pair of Pullets*.—First, C. Priest, Worthing. Second, Sir J. D. Wauchope, Bart. Commended, F. Pease, Southend; Miss A. Wilcox, Nailsea Court, Bristol.

DORKINGS (Coloured).—*Cock*.—First, Viscountess Holmesdale. Second, T. Statter, Manchester. Highly Commended, C. Priest, Worthing; W. G. Bannister, Woodbridge, Suffolk; Sir J. D. Wauchope, Bart. Commended, J. White, Warlaby; F. Pease, Southend; Rev. J. F. Newton, Kirby; Rev. J. G. A. Baker, Old Warden.

DORKINGS (White).—First and Cup, J. Robinson, Garstang. Second, D. Parsons, Cuerton. *Chickens*.—First, J. Robinson. Second, H. Lingwood, Needham Market, Suffolk.

COCHIN-CHINA (Cinnamon and Buff).—First, Capt. H. Heaton, Manchester. Second, H. Bates, Birmingham. Commended, C. T. Bishop, Lenton, Nottingham. *Chickens*.—First and Cup, Capt. H. Heaton. Second, T. Stretch, Ormskirk. Highly Commended, A. Perkins, Darlington. Commended, J. Nelson, Heaton, Mersey.

COCHIN-CHINA (Any other variety).—First, Rev. F. Taylor, Kirby Lonsdale, Second, W. Dawson, Hopton Mirfield. *Chickens*.—First, W. Dawson. Second, T. Stretch, Ormskirk. Highly Commended, Rev. F. Taylor; H. Bagge, Cambridge. Commended, H. S. Stobart, Witton Tower.

COCHIN-CHINA (Any variety).—*Pair of Pullets*.—First, H. Bates, Birmingham. Second, Capt. H. Heaton, Manchester. Highly Commended, C. Kershaw, Ashton-under-Lyne; A. Perkins, Darlington. Commended, W. Gamon, Thornton-le-Moors, Chester.

COCHIN-CHINA (Any variety).—*Cock*.—First, Capt. H. Heaton, Manchester. Second, A. Perkins, Darlington. Highly Commended, J. Nelson, Heaton Mersey, Manchester. Commended, H. Bates, Birmingham; W. Dawson, Hopton; Rev. J. G. Milner.

BAHAMA POOTRAS.—First and Cup, R. W. Boyle. Second, H. Lacy Hebdon Bridge. Highly Commended, C. Priest, Worthing. *Chickens*.—First, R. W. Boyle. Second, H. Lacy. Highly Commended, F. Pease, Southend; C. Priest. Commended, Rev. A. D. Shatto, Brancapeth Rectory; F. Pease; E. Greenwood, Burnley; J. Wright, Woodbridge.

BAHAMA POOTRAS.—*Cock*.—First, R. W. Boyle, Dundrum. Second, J. Wright, Woodbridge. Highly Commended, C. Priest, Worthing. Commended, T. Statter, Manchester.

GAME (Black-breasted and other Reds).—First, J. Fletcher, Stoneclough, Manchester. Second, H. M. Julian, Hull. Highly Commended, T. Robinson, Ulverston; G. W. Binns, Darlington. *Chickens*.—First and Cup, E. Aykroyd, Bradford. Second, J. Smith, Grantham. Third, Sir St. G. Gore, Bart. Highly Commended, J. Fletcher, Stoneclough.

GAME (Any other variety).—First, W. J. Cope, Barnsley. Second, Sir St. G. Gore, Bart. *Chickens*.—First, Sir St. G. Gore, Bart. Second, E. Aykroyd, Bradford.

GAME (Any variety).—*Cock*.—First, Sir St. G. Gore, Bart. Second, J. Smith, Breeder Hills. Highly Commended, J. Fletcher, Stoneclough; G. Founder, Kirby Moorside; T. Statter, Manchester; H. M. Julian, Hull. *Cockerel*.—First and Cup, E. Aykroyd, Bradford. Second, M. Billing, jun., Erdington. Highly Commended, T. Statter; Sir St. G. Gore, Bart. Commended, H. Thompson, Old Hutton; A. Perkins, Darlington.

GAME (Any variety).—*Pair of Pullets*.—First, J. Fletcher, Stoneclough. Second, W. J. Pope, Biggleswade. Highly Commended, E. Aykroyd, Bradford; A. Perkins, Darlington; T. Robinson, Ulverston; F. L. Roy, jun., Newthorn, Kelso.

HAMBURGHS (Gold and Silver-pencilled).—First, J. Robinson, Garstang. Second, H. Beldon, Gilstead. Highly Commended, Viscountess Holmesdale. Commended, J. E. Powers, Biggleswade.

HAMBURGH (Gold and Silver-spangled).—First and Cup, H. Beldon, Gilstead. Second, Sir St. G. Gore, Bart. Highly Commended, W. K. Duxbury, Leeds; J. Robinson, Garstang; J. Shorthouse, Newcastle-on-Tyne; T. Davies, Newport, Monmouthshire; T. Burch, Sheffield.

HAMBURGH (Golden-pencilled).—*Chickens*.—First, J. Robinson, Garstang. Second, W. H. Dyson, Bradford. Highly Commended, Rev. R. Roy, Worcester; Sir St. G. Gore, Bart. Commended, A. Nustall, Newchurch; J. Sunderland.

HAMBURGH (Golden-spangled).—*Chickens*.—First, Sir St. G. Gore, Bart. Second, B. Boynes, Keighley. Highly Commended, H. Beldon, Gilstead; T. Burch, Sheffield. Commended, W. K. Duxbury, Leeds.

HAMBURGH (Silver-pencilled).—*Chickens*.—First, J. Robinson, Garstang. Second, Sir St. G. Gore, Bart.

HAMBURGH (Silver-spangled).—*Chickens*.—First, Sir St. G. Gore, Bart. Second, H. Beldon, Gilstead. Highly Commended, Mrs. Sharp, Bradford. *Polands (Black with White Crests)*.—First, J. Smith, Keighley. Second, F. Pease, Southend. Disqualified, H. Carter, Upper Thong, Holmfirth, legs painted.

Polands (Gold or Silver-spangled).—First, H. Beldon, Gilstead. Second, F. Pease, Southend. Highly Commended, H. Beldon; F. Pease. Commended, F. Pease.

BANTAMS (Gold and Silver-laced).—First and Second, F. L. Roy, jun., Newthorn, N.B. Highly Commended, J. Crossland, jun.; F. Pease; W. K. Duxbury, Leeds. Commended, J. Crossland, jun.

BANTAMS (White and Black).—First, T. Davies, Newport. Second, J. Crossland, jun., Wakefield. Highly Commended, Sir St. G. Gore, Bart. Commended, T. J. Charlton, Manningham.

BANTAMS (Game).—First and Cup, J. Crossland, jun. Second, Sir St. G. Gore, Bart. Highly Commended, Hon. W. T. W. Fitzwilliam, Wentworth; J. Crossland, jun.; G. Smith, Waverley, Derbyshire; J. Barker, Sunderland.

BANTAMS (Game).—*Cock*.—First, F. Pease, Southend. Second, Sir St. G. Gore, Bart. Highly Commended, E. Brown, Sheffield; W. Rogers, Sunderland.

DUCKS (Aylesbury).—First and Cup, J. Smith, Breeder Hills. Second, Mrs. Seemons, Aylesbury. *Ducklings*.—First and Second, Mrs. Seemons. Commended, J. Eden, Greenbury, Scorton.

Ducks (Rouen).—First, J. Nelson, Heaton Mersey, Manchester. Second,

T. H. Barker, Hovingham. *Ducklings*.—First and Cup, R. W. Boyle, Dun-drum. Second, T. Statter, Manchester. Commended, J. Nelson; W. Gamon, Thornton-le-Moor; J. D. Newsome, Batley.

Ducks (Any other variety).—First, Sir St. G. Gore, Bart. Second, T. H. D. Bayley, Bigglewade, Beds. Highly Commended, F. Pease, Southend; W. A. Wooller, Darlington; S. Burn, Whitby; J. Harris, Darlington. Commended, E. Stamper, Darlington; J. R. Jessop, Hull.

Geese.—First, Mrs. Seamons, Aylesbury. Second, W. K. Duxbury, Leeds. Highly Commended, F. Pease, Southend. *Goslings*.—First and Cup, R. W. Boyle, Duxbury. Second, W. K. Duxbury, Leeds.

Turkeys.—First, F. Pease, Southend. Second, J. Smith, Breeder Hills. Highly Commended, Mrs. Bolland. *Poults*.—First and Cup, J. Smith. Second, F. Pease. Highly Commended, Rev. P. W. Storey, Dewsbury.

Turkeys.—*Cock*.—First, F. Pease. Second, J. Smith.

ANY OTHER DISTINCT BREED.—First, W. K. Duxbury, Leeds. Second, H. Beldon, Gilstead (White Polands). Highly Commended, F. Pease (Cochin Bantams).

SELLING CLASS (Any breed).—First, Rev. P. W. Storey, Daventry. Second, J. Robinson, Garstang (Golden-spangled Hamburgs). Third, Miss Roy, Keiso, N.B. (Brahma Pootras). Highly Commended, G. Yeats, Studley, Ripon (Coloured Dorkings); W. Lawrenson, Eaglescliffe. Commended, Hon. W. T. W. Fitzwilliam, Wentworth (Golden-pencilled Hamburgs); W. Massey, Gedney (Buff Cochins); J. White, Warlaby; F. Pease, Southend (White Cochin and Brahma Pootras); W. K. Duxbury, Leeds; Sir St. G. Gore, Bart.; T. Clemenson, Darlington (Brown Red Game).

EXTRA STOCK.—Highly Commended and Commended, F. Pease, Southend (Golden and Silver Pheasants).

Pigeons.—*Carrier Cock* (Any colour).—First and Second, T. Colley, Sheffield. Highly Commended, J. Thompson, Bingley. Commended, W. Woolley, Bunbury, Cheshire. *Hen*.—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, F. Else, Bayswater. *Powter Cock* (Any colour).—First and Second, G. R. Potts, Sunderland. Highly Commended, S. Robson, Burton Salmon. Commended, H. Brown, Sheffield. *Hen*.—First and Cup, G. R. Potts. Second, H. Brown. Highly Commended, G. R. Potts. *Tumblers* (Almond).—First, F. Else, Bayswater. Second, T. Rodham, Guisborough. *Tumblers* (Any other variety).—First, W. H. C. Oates, Besthorpe, Newark. Second, H. Yardley, Birmingham. *Fantails*.—First, W. B. Van Haansbergen, Newcastle. Second, F. Else, Bayswater. *Trumpeters*.—First, J. R. Robinson, Sunderland. Second, F. Else. *Barbs*.—First, W. B. Van Haansbergen, Newcastle. Second, W. Wooley, Bunbury. *Jacobins*.—First and Second, J. Thompson, Bingley. Highly Commended, J. T. Phipps, Darlington. *Turbits*.—First and Second, H. Yardley, Birmingham. Highly Commended, T. C. Taylor, Middlesbrough. *Owls*.—First, J. R. Robinson, Sunderland. Second, F. Else. Highly Commended, H. Yardley. *Any other New or Distinct variety*.—First, W. B. Van Haansbergen. Second and Highly Commended, H. Yardley (Spots and Satinettes).

Mr. Edward Hewitt, of Sparkbrook, Birmingham, and Mr. Richard Teebay, of Fulwood, Preston, judged all classes except Game; the Game fowls coming exclusively under the jurisdiction of Mr. Thomas Challoner, of Chesterfield; and Mr. W. Thompson, of Southowram, Halifax, officiated for the Pigeons.

YORKSHIRE SOCIETY'S POULTRY, PIGEON, AND RABBIT SHOW.

(From a Correspondent.)

THE eighth annual Exhibition of this flourishing Society terminated at York, on Friday, the 2nd inst., with results highly satisfactory to its promoters. This year a large additional attraction to the Show, was created by the introduction of Pigeons and Rabbits, and the receipts were about £100 in excess of last year. There was a good show, embracing 265 pens of poultry, 276 of Pigeons, and 52 Rabbits. The birds were well arranged, and the building is well adapted for the purpose. The city of York being very central for such an Exhibition, I hope next year to see a large increase in the entries. It must be borne in mind that this year the Birmingham Show was going on at the same time, nevertheless, the poultry and Pigeon classes were all well filled with first-class birds from some of the principal breeders and exhibitors in England. The Rabbits were also well represented, though next year I anticipate some additional classes for the various colours, &c. I submit the following notes on the various classes.

Dorkings, the second-prize pen I think ought to have been first, and Mr. Pease, of Darlington, showed a splendid pen of Whites, which certainly ought to have been noticed. In the chicken class the birds were of great merit, and I think fairly judged. The Spanish classes, both adults and chickens, contained some excellent birds. The Cochins were well represented, there being twenty-five entries; but I was sorry to see only one class for all the varieties. The Game classes were all well filled, but no birds of any particular merit shown. The four classes of Hamburgs were also well represented with some beautiful specimens, though in some classes I think they were not at all well judged, especially the Silver-spangled. There was a good display of Polands, Miss Beldon taking first with a splendid pen of Silvers. In

the "Any variety" class there were nineteen entries, ten of them being for Brahma Pootras, thus showing the necessity of establishing a separate class for these birds. There were also some entries of them in the "selling class." In Game Bantams there were sixteen entries. The first prize went to a beautiful pen shown by Mr. George Smith, Staveley, Chesterfield. In Bantams of any other variety, there were twelve entries. The first prize went to Mr. R. Pease, Darlington, for a splendid pen of Silver-laced.

In Ducks, Rouen, or any other variety, there was a large entry, but the judging has given very great dissatisfaction. The Aylesbury Ducks, Geese and Turkeys, were all well represented, and I think fairly judged.

In Pigeons there was great competition in the Carrier classes, there being twenty-nine entries for the best cock of any colour, and twenty-seven for hens. It is generally considered that the cocks were fairly judged; but in hens it is thought the second-prize Dun, belonging to Mr. F. Else, Bayswater, ought to have been first. In Powter cocks of any colour there were twenty-two entries; and in hens of any colour, there were nineteen entries. The general opinion of fanciers is, that in these two classes the birds were not at all judged rightly, as in the cock class there was a fine display, consisting of Mealies, Whites, and Blues, belonging to one of our famous breeders, Mr. Henry Simpson, of Newark, and I consider one of his Mealy birds to be the finest style of bird ever seen, having symmetry in every point. His white Powters were also of great merit, the first-prize bird belonging to Mr. S. Robson, Brotherton, having been bred by him, gives him great credit. The Short-faced Tumblers were not well represented. In Tumblers of any other variety, there was a very good show of this class of bird, they being represented by many good specimens. In Fantails there was an extraordinary show, they being represented by twenty-one entries, containing many first-class birds. The Trumpeter class was well filled, containing seventeen entries. In the Barb class there were no birds of extraordinary character. In the "Any other variety" class there was a fine display of birds, and twenty entries, the first prize going to Nuns. There was a good display of foreign specimens, but I was sorry to see none of them noticed. The "selling class" was well filled with forty-two entries, the first prize being carried by Barbs, the second by Fantails belonging to Mr. H. Simpson, Newark. Mr. Simpson's Fantails could have been claimed at least ten times over.

There was an excellent show of Rabbits, including some very fine specimens shown by Mr. Ridpath, of Manchester. The first prize tortoiseshell buck exhibited by Mr. Alex. Cattley, of York, was a fine specimen, and well deserving of its place. The entry for Dutch was only small, but the specimens were good. In Himalayans there was only one entry.

The following is the list of prizes awarded:—

Dorkings.—First, Miss E. Beldon, Gilstead, Bingley. Second, T. E. Bell, Wetherby. *Chickens*.—Prize, F. R. Pease, Southend, Darlington.

Spanish.—First, G. Jackson, York. Second, Miss E. Beldon, Gilstead.

Chickens.—Prize, S. Robson, Brotherton.

Cochin-China.—First, T. H. Barker, Hovingham. Second, H. A. Hudson, Ousecliffe, York. *Chickens*.—Prize, R. Dewes, Knaresborough.

Game (Black-breasted or other Reds).—First, J. Sunderland, Halifax.

Second, Miss E. Beldon, Gilstead.

Game (Any other variety).—First, H. M. Julian, Hull. Second, T. Hartley, Head Leig. *Chickens*.—Prize, W. K. Duxbury, Leeds.

HAMBURG (Golden-pencilled).—First, Miss E. Beldon, Gilstead. Second, A. Nuttall, Newchurch, Manchester.

HAMBURG (Silver-pencilled).—First, J. Sunderland. Second, D. Illingworth, Burley, near Otley.

HAMBURG (Golden-spangled).—First, Miss E. Beldon, Gilstead. Second, I. Todd, Newall-with Clifton, Otley.

HAMBURG (Silver-spangled).—First, Miss E. Beldon. Second, C. Outram, Sheffield.

Polish (Any variety).—First, Miss E. Beldon. Second, R. Jessop, Hull.

ANY FARMYARD CROSS, OR OTHER VARIETY NOT PREVIOUSLY CLASSED.—First, R. Loft, Woodmansey, Beverley. Second, Miss E. Beldon. Third, E. Leech, Rochdale.

BANTAMS (Game).—First, G. Smith, Staveley, Chesterfield. Second, G. Cutler, Malinbridge, Sheffield.

BANTAMS (Any other variety).—First, F. R. Pease, Southend, Darlington. Second, Miss E. Beldon.

Turkeys.—First, F. R. Pease. Second, Mrs. Legard, Poppleton. *Poults*.

—First, Mrs. E. Hick, Heelington, York. Second, E. Leech, Rochdale.

Geese.—First, W. K. Duxbury, Leeds. Second, F. R. Pease, Southend, Darlington.

Ducks (Aylesbury).—First, E. Leech, Rochdale. Second, O. A. Young, Driffield.

Ducks (Rouen or any other).—First, J. K. Jessop, Hull (East Indian). Second, W. K. Duxbury, Leeds.

SELLING CLASS (Any variety).—First, T. Hartley, Gomersall. Second, Miss E. Beldon. Third, W. Harker, Cottingley, Bingley.

EXTRA POULTRY.—Prizes were awarded to F. Powell, Knaresborough, and T. Watson, Heworth, York.

PIGEONS.—*Carrier Cock* (Any colour).—First, G. H. Sanday, Holme Pierrepont, Nottingham. Second, A. F. Leite, Manchester. *Hen*.—First, T. Colley, Sheffield. Second, F. Else, Bayswater, London. *Pouter Cock* (Any colour).—First, S. Robson, Brotherton, Burton Salmon. Second, G. R. Potts, Sunderland. *Hen*.—First, H. Brown, Walkley, Sheffield. Second, H. Simpson, Newark, Notts. *Tumblers* (Short-faced, any colour).—First, J. R. Jessop, Hull. Second, H. Yardley, Birmingham. *Tumblers* (Any other variety).—First, I. Todd, Newall-with-Clifton, Otley. Second, H. Simpson, Newark. *Fantails*.—First, E. Horner, Harewood, Leeds. Second, T. Hives, Cotgrave, Nottingham. *Trumpeters*.—First, Miss E. Beldon. Second, F. Else. *Bars*.—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, H. Yardley, Birmingham. *Jacobins*.—First, J. Thompson, Bingley. Second, G. H. Sanday, Nottingham. *Turbits*.—First, H. Yardley. Second, G. Fletcher, Acomb, York. *Owls*.—First, G. A. Sanday. Second, F. Else. Any other New or Distinct variety.—First, O. A. Young, Driffield. Second, T. R. Trenam, Helmsley. *Selling Class* (Any breed).—First, J. R. Robinson, Sunderland. Second, H. Simpson, Newark.

RABBITS.—*Long-eared Buck* (Any colour).—First, A. Cattley, York. Second, T. H. Ridpath, Rusholme, Manchester. *Doe*.—First, T. H. Ridpath. Second, G. Calvert, York. *Himalayan*.—Prize, J. W. Frier, York. *Dutch*.—First, S. Hall, York. Second, G. Jackson, York.

The Judges were Mr. J. W. Thompson, Southowram, near Halifax; Mr. James Smith, Walkley, near Sheffield; and Mr. Harry Adams, Beverley.

THE BRIGHTON POULTRY EXHIBITION.

We are not aware of any local poultry show that has so speedily won its way into public favour as that under the management of the Brighton committee. Although only three years have passed since its first institution, and though beginning in a very small way, its promoters were in no wise disheartened. Last year great progress was evident, and the exhibition just concluded was quite equal to the best of local meetings of this character. We trust so satisfactory an issue may conduce to similar exhibitions in the surrounding districts being speedily restored to the high position they held some ten years ago; for the falling off in the number of shows in the south of England is certainly rather to be attributed to the supineness of committees than to any indisposition on the part of either the general public or exhibitors to support them.

The exhibition at Brighton proved a most successful one in coloured *Dorkings*, the specimens exhibited by the Marchioness of Bath being such as would be highly creditable to any show. The chickens were peculiarly fine and well-grown birds, the best for their age we have this year met with, and there is not much reason to doubt that we shall speedily hear of them again at the head of other prize lists. Some good specimens were shown in the class for the best coloured Dorking cockerel, but from some cause or other several old birds put in an appearance, that, of course, met with instant disqualification. Exhibitors cannot possibly be too careful in consulting their prize schedules before entering, as no two lists are probably alike, and the conditions they impose must necessarily be enforced to the letter. The Game classes were decidedly the least perfect of any in the showyard, and the entries were unusually limited. Black Spanish were good, but had barely recovered from moulting. The best feature in the Brighton Show was the *Brahmas*, of which twenty-seven pens were on the spot. It is not beyond their desert to say that this collection was quite equal to any we ever saw at even the largest of our poultry shows. The excellence of these birds throughout, whether dark or light coloured, was so remarkable, that they formed the chief attraction of the meeting, and never was competition so severe. The *Cochins* were not a large nor a very perfect class; but the *Hamburgs* were particularly fine, especially the Golden-pencilled ones. The *Polish* were also good. In Game *Bantams* there was a good display, Mr. Kelleway, of the Isle of Wight, taking the chief honours with uncommonly neat and beautiful specimens. Mrs. Seemons, of Aylesbury, took her accustomed place in the prize list, her best pen of three birds weighing 27 lbs.

The *Turkeys* and *Geese* were well represented, and the Show was favoured with a first-rate attendance, the weather being quite summerlike.

DORKINGS (Coloured).—First and Second, Marchioness Dowager of Bath, Worthing. Third, A. Stanford, Eatons, Steyning. Highly Commended, Marchioness Dowager of Bath; W. Stanhope, jun. Commended, A. Stanford. *Chickens*.—First and Second, Marchioness Dowager of Bath. Third, T. Roper, Barham, Suffolk. Highly Commended, Marchioness Dowager of

Bath; A. Stanford. Commended, G. Hudson; Sir P. Burrell, Bart., M.P.; — Hawes, Hayes, Horsham. *Cockerels*.—First, A. Stanford. Second, Rev. J. G. A. Baker, Biggleswade. Third, Marchioness Dowager of Bath. Highly Commended, Sir P. Burrell, Bart., M.P.

GAME.—First, Rev. T. C. Rose, Little Wymondley, Stevenage. Second, H. Gorringe. Third, G. Boniface, jun., Ford, Arundel. Commended, H. Gorringe. *Chickens*.—First, G. Boniface, jun. Second, G. W. Ranwell, Portsea. Third, W. J. Pope, Biggleswade, Beds. *Sweepstakes Single Cocks*.—First, and Third, G. Boniface, jun. Second, H. Gorringe.

SPANISH (Black).—First, J. H. A. Jenner, Lewes. Second, R. Wright, London. Third, Rev. J. de la S. Simmonds, Winchester. *Chickens*.—First, E. Draper, Northampton. Second, A. Heath, Calne, Wiltshire. Third, W. R. Bull, Arundel. Highly Commended, W. R. Bull. Commended, O. E. Cresswell, Hanworth, Hounslow; Rev. J. de la S. Simmonds.

BRAMHA POOTRA.—First and Third, Marchioness Dowager of Bath Second, C. Cork, Shoreham. Highly Commended, Marchioness Dowager of Bath; Rev. T. C. Rose, Stevenage; W. L. Barclay, London; R. Ede, Worthing. Commended, Marchioness Dowager of Bath; J. Pares.

COCHIN-CHINA.—First, T. W. Russ, Hastings. Second, Mrs. M. Seemons, Third, Mrs. Prescott. Highly Commended, F. Zurhorst, Donnybrook, *Polish* (Any variety).—First, J. Hinon. Second, Edwards, Lyndhurst Third, D. Mutton, Brighton.

HAMBURGS (Gold-pencilled or Spangled).—First and Second, F. Pittis, jun., Newport. Third, — Hunter, New Malden, Surrey. Highly Commended, G. Edgar, Lancing.

HAMBURGS (Silver-pencilled or Spangled).—First, Marchioness Dowager of Bath. Second, — Pyne, South Lancing. Third, — Saltmarsh, Chelmsford.

BANTAMS (Any variety).—First and Second, J. Kelleway, Merton, Isle of Wight. Third, F. Pittis, jun. Highly Commended, Hon. F. Petre, Brentwood. Commended, E. Pigeon, Lympton, Exeter.

ANY VARIETY NOT PREVIOUSLY MENTIONED.—First, F. Zurhorst, Donnybrook (Sultans). Second, — Cothen, Salisbury (Malay Pheasant). Third, Marchioness Dowager of Bath (Silkies). Highly Commended, — Edwards, Lyndhurst (White Dorking); J. Willett, Lewes (White Dorking); E. Pigeon, Lympton (*La Flèche*); Mrs. Brasseys, jun. (*Crève Coeur*). Commended, J. Pares, Chertsey (Andalusian); J. Hinton, Hinton, Bath (Malays); Marchioness Dowager of Bath (Silkies).

GESE.—First, Mrs. Seemons, Aylesbury. Second, — Barclay (Toulouse). Third, Sir P. Burrell, Bart., M.P. Highly Commended, T. Poole, Brighton (Spanish).

DUCKS (Aylesbury).—First and Second, Mrs. M. Seemons, Hartwell, Aylesbury. Third, — Willett, Lewes. Highly Commended, — Parlett, Chelmsford.

DUCKS (Any other variety).—First, W. Stanford, jun. (East Indian). Second, J. Adams, Farham. Third, Marchioness Dowager of Bath (Rouen). Highly Commended, — Barclay; Marchioness Dowager of Bath (Rouen). Commended, Sir P. Burrell, Bart., M.P.; E. Pigeon, Lympton (East Indian).

TURKEYS.—First, Lady Macdonald, Liphook, Hants. Second, Miss Millward. Third, W. Newland, Broadwater. Highly Commended, — Humphrey, Ashington.

PIGEONS (Dragons or Carriers).—First and Second, E. Draper, Northampton (Carriers). Third, — Cork, Shoreham (Blue Dragons).

PIGEONS (Any other variety).—First, Dr. Gream (Powters). Second, — Bunce, Walworth (Black Mottled Tumblers). Third, A. Middleton, Newport (Turbits). Highly Commended, — Bunce, (Almond Tumblers); — Amore, Brighton (Ascosa). Commended, — Amore (Norman Black).

James Turner, Esq., of Chyneton, Sussex; and Edward Hewitt, Esq., of Sparkbrook, Birmingham, officiated as the Judges.

CREVE COEUR FOWLS.

For two seasons past I have kept Crèvè Coeur fowls and have raised a large number of chickens. My stock birds were all prizetakers, carefully matched for breeding, and the runs they and the chickens were on had done well for Cochins and Hamburgs. But almost without exception I find the tails, especially of the male birds, wanting in firmness and hardness of feather, so that they are very apt to break and so spoil the appearance of the birds.

I have noticed the same bad tails in birds of this breed raised by other breeders, in imported birds, and even in some that were exhibited at the Birmingham show; and a defect of this nature would be a strong objection to the keeping of a breed undoubtedly very valuable as egg-producers and non-sitters.—W. B., Lancashire.

[We have kept them largely, and have not noticed the peculiarity named by our correspondent. They are by no means hard-feathered fowls. The La Flèche are before them in this particular.]

AWARDS AT THE SOUTHAMPTON BIRD SHOW.

You will very much oblige by contradicting the statement made by Mr. Taylor, of Portsea, respecting my dissatisfaction at the awards at the late Southampton Show. I am perfectly satisfied with the Judges. When the case of Mr. Triggs' bird was brought before me I stated that his bird, as he then appeared, certainly looked the best bird, but adding, doubt-

less when the Judges went round the bird may have been out of condition.

I agree with Mr Taylor that more time should be allowed for judging such as the Palace Show, where there should be a day expressly for judging, and the birds should be at the Show a whole day previously, as many of them come a long distance, and are so exhausted that it requires a day for them to recover.—THOS. MOORE, Fareham.

DUCKS LAYING BAD EGGS.

THE Duck was hatched last spring, and commenced laying about ten days ago, and has laid half a dozen eggs and every one of them bad. The whites are bluish, and the yolks are the colour of a sponge, or, if anything, a little darker.—W. Y. M.

[It may be the result of disease or of improper food. Such things do sometimes happen with first eggs; and if you cannot attribute it in any way to the former causes, we think we may safely tell you that a little patience will probably be the cure.]

SITTING HEN EATING HER EGGS.

IN answer to "J. W.'s" question respecting the hen eating her eggs when sitting, I can say I had one that did so last year. She is a very good hen to lay, and I did not wish to kill her, so I thought I would try to remedy the evil. She used to keep on her eggs for two or three days together, and that was when she ate her eggs. So I thought it was hunger, and I made it a practice to turn her off every morning at feeding time, and I then found she ceased to eat any eggs. I think your correspondent will find that this propensity is caused by hunger through remaining on the nest too long.—ELMWOOD.

THE RECENT MILD WEATHER—A CAUTION.

TO-DAY has been quite like summer—the sun very warm, scarcely a breath of wind stirring. My bees (five stocks), have been out of their hives quite as numerously as on many days in September. I am afraid it is a bad sign, but should like to know if any of your correspondents have found their bees do the same.—J. W. T., Wandsworth.

[Permit me to address a word of caution to the aparian readers of THE JOURNAL OF HORTICULTURE. The recent mild weather appears to have stimulated a very rapid consumption of the stores in hives intended to stand the winter. I am almost ashamed to confess that I have already lost a fine stock from sheer starvation, but I deem it right to make my misfortune public as a warning to others. I made up all my stocks to what I deemed a sufficient weight in October, and was quite taken by surprise at finding, only two months afterwards, one dead of starvation, and some of the others so light as to necessitate prompt measures to save them from the same fate. The consumption of food by my bees this autumn has certainly been remarkably great, and it has very probably been the same with others. The appearance of this note of warning may save some of my brother aparians from a similar misfortune to that experienced by—A DEVONSHIRE BEE-KEEPER.]

BEES REGICIDAL—DRIVING BEES.

SOME time ago "A DEVONSHIRE BEE-KEEPER" asked the readers of THE JOURNAL OF HORTICULTURE if any explanation could be given by them as to the strange aberrations of regicidal attacks on queens. Now, I dare not venture to explain the cause; but, nevertheless, it does not hinder me giving a few hints of what has come under my own observation. It is a well-known fact that at swarming time bees, which intend doing so, often try to take possession of any weak hives that may be near, and succeed in doing so. The first thing they do after they do gain admittance is to kill the queen. This I have often seen. Since the introduction of the Ligurian bees into this locality they have shown their thievish propensities by attacking both the black bees and the weak hives of their own race. About

a month ago, one day, after feeding a Ligurian hive, my attention was drawn to a black hive, and I saw numbers of Ligurians marching in and out just as if they were at home, and on drawing the shutters and taking a peep at the interior, there were the yellow bees nibbling away at the black at the very top of the hive, and in a few hours the queen was thrown out dead. Might it then not be strange bees that killed the queen, and not her own subjects? as they, being weak hives, might be easily overcome, and the queen on her return could be easily made captive by a few strange ones.

I see that "C. D., Sheffield," complains that it is with difficulty that he can induce the bees to leave wooden hives. For my part I never found any difference if the weather was at all favourable. I have often driven them in winter when necessity required, and instead of cutting-out combs and brushing the bees into an empty hive when I found them a little dilatory, I simply tied a thin muslin cloth or such like over the mouth of the inverted hive, and placed it before a fire, not too near, for a short time, and then I accomplished my end easily.—A LANARKSHIRE BEE-KEEPER.

A NEW BEE BOOK.

THE question has been asked, "Is a new bee book wanted?" In these days of rapid book-making, there is a great lack of originality, a new book too often proving but old material dressed up in a new form, and from a want of practical knowledge of the subject treated of, the compiler is apt to introduce absurd errors and exploded theories, of which style "Bee-keeping, by the *Times Bee-master*" may serve as an illustration, and of such books we have certainly no need.

But there is a want felt amongst aparians generally, of a thoroughly original and practical work on bee-keeping at a moderate cost, embracing what was useful and well established in the past, together with all the more recent discoveries and improvements. The acquaintanceship of "A DEVONSHIRE BEE-KEEPER" with the bee literature of his own and other countries, and, above all, his extensive practical experience of both the British and Italian bee, long ago induced me to express to himself the hope that one day he might be induced to favour us with what I felt sure would prove a standard work on the subject, "the right man being in the right place." This hope it affords me the greatest pleasure to find is about to be realised; and as the knowledge of our interesting little favourites progresses, that he may be spared to put it through many editions, is, I feel sure, the sincere wish of all the readers of the aparian corner, as well as of—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

WASHING FOWLS—HARDENING PLUMAGE (*H. S.*).—If dirty the birds should be washed, and not more than two days before they go to the show. Peas and small beans will harden a cock's plumage—raw yolk of eggs will do the same.

FEATHERS OF SPANGLED HAMBURGH PULLETS (*Golden Hamburg*).—If you sell all the Spangled pullets that have a few white spots you will be likely to sell all. They all have them under the belly and towards the tail. We do not consider them at all important there. We should think them a defect on the chest or back. The first-prize Birmingham birds were very good in our opinion. We should not consider a few white spots sufficient reason for discarding a hen. Their belly plumage is commonly coloured to hide the white spots.

BIRMINGHAM PRIZE LIST.—In the coloured Dorking chicken class Mr. S. Lang, Jun., The Shrubbery, Redland, Bristol, should have appeared in our list as the owner of a highly commended pen.

COCHIN-CHINA COCKEREL (*W. H. Wheeler*).—The thumb mark in his comb is not of the slightest consequence in a stock bird.

MICE IN AN AVIARY (*Ivy Hedge*).—The best means of getting rid of the mice is by poison placed outside of the aviary, provided it is not used carelessly and poison something besides the mice. We have known many small birds killed by mice during the night time. Phosphoric paste is the best, but it must be used very carefully. If the aviary stands by itself zinc 18 inches high round the bottom will prevent the mice getting in; but if it joins a wall or building then the wirework should be made close, so they cannot get through.

BREEDING LIGURIAN BEES (*A. L. B.*).—We should suspect some taint of the common black bee in a Ligurian queen that bred only very dark workers with but one orange-coloured band, and we would not breed queenes from her unless compelled to do so in the absence of a better.

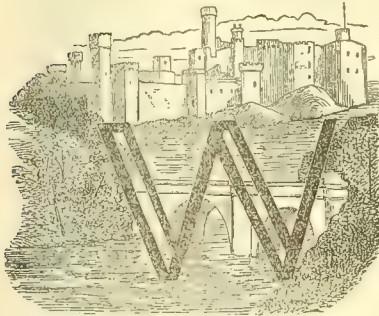

MOVING A HIVE TO A DISTANCE (*H. A. H.*).—Secure the hive, one of Neighbour's improved cottagers, with windows, firmly to its floorboard, cover the entrance and the holes in the top of the hive with perforated zinc; tie a cord round it, do not trust it in the hands of railway porters, and let it travel in the same carriage with yourself.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 43.8°, and its night temperature 32.0°. The greatest heat was 58° on the 25th, 1827; and the lowest cold, 4°, on the 24th, 1860. The greatest fall of rain was 1.13 inch.

THE FILBERT AND COB NUTS.

ITH the exception of the Grape Vine there is no fruit tree with which I am acquainted so much indebted to pruning for rendering it fruitful as the Filbert. I believe that I do not exaggerate when I state that the severity with

which this tree is cut in exceeds even that by which the best Grapes are generally obtained. Such severe mutilation would very quickly cause disease and death in a tree less robust and less tenacious of life, but the Filbert endures all for many years, and rarely succumbs, some plantations being quite fifty years old, although other reasons often afford a cause for removing them before that time. Filberts are often met with as a sort of undergrowth to fruit trees of larger dimensions, as standard Apple, Pear, Plum, or Cherry trees; but they are also frequently allowed a plot to themselves, and certainly, where the soil and other circumstances favour their growth, they well deserve a place where they will not be interfered with by other trees.

I believe it is generally admitted that the Filbert and Cob Nuts are importations from the Peninsula or some other district in central or southern Europe, and not a native improvement on the wild Hazel Nut of our coves and woods effected by long and persevering cultivation, as the Apple and Plum may have been. The economical value of the latter fruits being greater than that of the Nut, the desire to effect improvements was, no doubt, more earnest in their case than in that of the Nut, which was most probably regarded as a luxury. Dismissing that subject, however, I may remark that the same soil and situation in which the wild Hazel is found appears to be the best for the cultivated varieties —namely, hilly stony districts, neither too dry nor too wet, and of which the subsoil is penetrable by the roots of this and other trees. On such a soil is found the wild Hazel, and on such, too, the cultivated Cob and Filbert thrive the best. The aspect does not seem to be of so much consequence, as Filbert grounds are found in declivities facing all directions, not the least productive being those with a western aspect; while plenty having a northern one are equally successful; but all aspects are under this crop, and now and then a plot nearly level is met with. Generally hilly places are put under this crop after having been trenched, and part of the stones taken out. The heavy loam of low lands which produce the best Wheats does not appear to answer so well for the Filbert, and a drier position should therefore be selected.

No. 195.—VOL. VII., NEW SERIES.

The Filbert and Cob are propagated plentifully enough from suckers at the root, which are generally bedded in some nursery ground for a year or so before finally planting out, and they are headed down to within a foot of the ground, to obtain a series of branches radiating at that height, which are so cut and arranged as to form the skeleton of the future tree. This, when full grown, in some respects resembles a basin in shape, the centre being hollow, and the outer edges about 5 feet from the ground, the diameter being 12 feet or so. Where there is a large number of trees together, and they are carefully planted in lines at 12 feet apart each way, and trimmed as they usually are, the upper surface of the rim of each tree is an exact counterpart of its neighbour, and the eye of the observer passes over the whole in a line parallel with the ground. Each tree is cut as exactly at a certain height from the ground as corn usually is, and the only difference is that the Filberts are 5 feet from the surface, and the stubble only a few inches.

The mode in which the Filbert is trained might, perhaps, be very well copied in the case of other trees. The young tree, as already stated, is cut down so as to obtain a quantity of shoots at less than a foot from the ground, which are so cut as to secure others continuing to spread in all directions from the centre with so little rise that at the radius of 5 or 6 feet their tops may not be higher than at most 5 feet from the ground. This pruning and training, however, is the work of years, and while it is progressing lateral branches pointing in the same direction are left on and encouraged, taking care that whatever young wood is allowed to remain for such a purpose should be neither too strong nor too weak, the former only producing its like, and the latter being too insignificant to expect much from; but of the two extremes the latter is by far the preferable. Some other peculiarities in pruning are also well worthy of notice, and might, perhaps, be copied with advantage elsewhere. It is well known that the Filbert and Cob (both being alike in that respect), push shoots 6 feet long and upwards. These rampant shoots are sometimes situated where a branch is wanted, or where it would be imprudent to remove them entirely; and to cut them back with the knife in the usual way would only be to encourage another of a like kind from the one so operated upon. In cases of this kind the knife is laid aside, and a rough-toothed saw is used to cut through the shoot, leaving it in as haggled a condition as it well can be, and this coarse operation assists in checking the tendency of the same branch to produce other vigorous shoots; while all small shoots are shortened in by the knife in the same way as those of other fruit trees, the portion left rarely being more than 3 inches at any place, and often less in the full-grown tree. Neither are the main and subsidiary branches at all close, the practice being to get a few (what might appear), gnarled, ugly, stumpy branches with a few spurs on equally uninviting to look at; but the practised pruner can tell tolerably well by the appearance of the tree which are fruit-bearing spurs and which are not, although it is difficult to explain how on

No. 847.—VOL. XXXII., OLD SERIES.

paper. In general such shoots are small and short-jointed, and about the end of January, if the winter has not been unusually severe, small pink spots will appear, showing through the bud, these are the female blossoms, and form the embryo of the fruit; the male blossoms are expanded, and hang in catkins months before these appear. It is, therefore, better for those unacquainted with this tree not to begin to prune until these tokens of fruitfulness can be seen; at the same time it is not prudent to delay it too long, as they are easily rubbed off, and all prospect of fruit is then gone.

The female blossoms though expanded long before settled fine weather, are, nevertheless, tender, and easily injured by frost, and, therefore, a declivity facing the west is often thought to be the best, as the frosts of spring are often gone ere the sun can shine, and thus they escape injury. Overhanging Apple trees are likewise not altogether without their use, as they afford a little shade and shelter, so that large breadths of these trees and Filberts are planted together, while in not a few instances there is a crop of Hops overtopping the Filberts for some years; but this latter plan is not considered of any benefit to the Nuts, but is merely adopted to obtain the most from the ground. Gooseberry and Currant trees are by far the most common accompaniments, they being invariably planted to occupy the spaces between the Filberts while these are progressing. Assuming the latter to be planted at 12 feet apart each way, the small fruits might be 6 feet, or if the Nuts are 10 feet apart, the latter would be 5; so that for every Cob or Filbert there would be three Gooseberry or Currant trees, unless the latter or the Nuts were intermixed with standard Apple or other trees, which are often 20 feet or more apart. Generally, however, the ground is heavily cropped from the beginning, and it is by no means unusual to see Currants, Filberts, and Apple trees all growing together, the last overtopping the former two, and scarcely a speck of ground to be seen. It is very rare that a Filbert is seen on grass land, the opinion being that the tree derives advantage from tillage; and, on the other hand, as the Cherry is said to be injured by this, a Cherry orchard is generally laid down in grass. Such is the Kentish custom, and a long course of culture based, no doubt, on practical observations has determined this course to be the best in both cases.

Of the varieties most esteemed by the grower it is difficult to say much, the demand pointing out the kind most proper to grow; but there is little question that the quantity of Cobs now grown far exceeds that of Filberts, and that the culture of the former has been on the increase for many years, whilst that of the latter has been decreasing, few young plantations of these being made. The varieties of both are very limited in number as compared with those of other fruits. Sometimes when a grower has a reputation for fine fruit a local name attaches itself to the variety he cultivates, although in all probability no real distinction exists. However, there are some inferior kinds, and these it would be proper to weed out. Subjoined I give the names of a few, to which, doubtless, others might be added.

Common Cob.—I believe a much harder-shelled one than this is found in other counties, as the kind now called the common one is the same as Lambert's or Kentish Cob elsewhere. A good Nut, producing excellent clusters, with a large full kernel. I may mention that, for experiment, I once weighed a quantity of average quality, including the husks, as they were, and had them cracked, and then weighed the kernels alone, and these were found to be a trifle more than half the weight of the whole, and, therefore, the reader may form an idea that they were pretty full. The shell, however, is harder than that of the Filbert and improved Cosford Cob, but the kernel keeps better than the latter, and is equal to it in flavour.

Cosford Cob.—This only differs from the last in being thinner-shelled; as regards bearing it is much the same, and except that the common Cob keeps fresh longer, there is not much difference between the two.

Spanish Cob.—The distinction here is so questionable that it is doubtful if the Kentish and Spanish may not be synonymous. There are also other names, having reference to localities where large quantities are grown, but it is impossible to describe them as being applied to distinct varieties.

Red-skinned Filbert.—This is by many esteemed the finest

Nut grown, and for a month or more after gathering is unquestionably so, and most people admire it during that time. It does not, however, keep so well as the Cob, and, as a plant, is less prolific, or, rather, is more tender. A few plants, however, ought to be in every collection.

White or Common Filbert.—This is more hardy than the last, and bears better; it is also a very good nut.

Frizzled Filbert.—The husk which encloses the nut being fringed at the point has given this plant its name. As a curiosity it has its admirers, and the nut is also good, though not better than those above mentioned; but the peculiarity of the husk gives it a claim to notice.

Besides the above there are many others perhaps, with which I am but imperfectly acquainted. One variety is grown for the tint of its foliage resembling that of the Copper Beech, and is called the Purple-leaved. I believe, however, that its fruits are little, if at all, better than common hedge Nuts, its merit resting solely on its foliage. There is also said to be a Dwarf Prolific of high reputation, and which doubtless deserves notice, but not being acquainted with it I cannot speak of its merits. Possibly, however, other growers from localities equally favourable to the growth of Nuts will give us the benefit of their experience. There is no fruit that I am acquainted with of which the cultivation seems to be confined to so few districts as this. Assuredly the soils and situation suitable for it are more generally to be found than is commonly supposed, and there seems to be no reason why it should not be tried in many places in which there is every prospect of its succeeding.

J. ROBSON.

HARDY FERNS:

HOW I COLLECTED AND CULTIVATED THEM.—No. 6.

ALL my Fern journeys were not made in the shape of tours, where public conveyances and public inns threw one with a mixed society, giving to one's thoughts and associations a diffuse itinerant character. Some journeys there were, taken in choice companionship, which stand out clear and bright in my memory like sunlight on a hill, marking each blade of grass, each tiny flower, with a distinct existence of its own; so that I can say, "As I gathered this leaf my thoughts gathered round some subject, made clear to me for the first time by the light of the genius of my friend;" or, "As I uprooted this Fern a long-cherished prejudice was uprooted with it."

Insensibly in my mind certain Ferns have become the embodiment of certain graces; they act upon me as monitors, reminding me of voices passed away that I never heard save in tones of love and charity, luring me on to a life of truth and beauty open alike to all.

Amongst my brightest representative Ferns is the *Ceterach officinarum*. I have never found any difficulty in cultivating Ceterach. Although it is a little wayward in the choice of its own habitation, yet where it does grow the walls will be full of it, every niche and corner adorned by its prettily crimped fronds—now shining green, now russet brown, as the sunlight may fall. I have usually found Ceterach growing on old stone walls, where a good deal of lime has been used in the mortar. In this position the fronds do not attain any great luxuriance, and are often so curled that only the brown mass of spore-cases at the back is visible. It is sometimes to be found on rocks, and in this situation the fronds will reach 6 or even 7 inches in length, while the full fructification will form a little border of brown fur on the outer side. Whenever I look at Ceterach it seems to whisper to me—

"He prayeth best who loveth most'
All things both great and small;
For the dear God who loveth us,
He made and loveth all."

Bound on a pilgrimage to Clevedon in Somersetshire with a friend whose life taught me the spirit of the ancient mariner's rhyme, we stopped at the little village of Ashton near Clifton, and there, abounding in profusion, we found Ceterach. All the lower parts of the walls had been cleared by wayfarers like ourselves; but high above it hung out its green banners too temptingly to resist. We tried to reach it in vain. Old women in white, full-bordered cap, and neat kerchief, came out to look. "Would miss like a chair and

a knife?" Thus armed "miss" was invincible; and under the smiling protection of the old women she scooped out brick and stone, and a basketful of healthy plants, shortly to be put on the lower tier of the Warwickshire fernery. At La Spezzia in Italy I found a diminutive form of Ceterach, which might be called pinnate. It was growing on a rock within a few yards of the tideless sea, facing the glorious bay, where a whole fleet could ride at anchor. Nothing could exceed the grandeur of that Spezzia bay on a clear Sabbath morning in autumn, a cloudless sky overhead, and the deep blue waves breaking into white ripples about the huge men of war, whose gay pennons bespeak their nation. Eight-oared boats are passing from the ships to land, bringing, it may be, some of their crews to join the motley throng of worshippers gathered in the cathedral to hear mass. Some of the women kneeling there have white linen folded like dinner-napkins on their heads; others have the Spezzia hat—like a little cheeseplate, made of fancy straw, and trimmed with scarlet braid; others, again, have the Genoese headdress—a gay cotton shawl like a counterpane, wrapped round them, covering the head. Some are talking, some laughing gaily, but at the elevation of the Host every sound ceases, and every knee is bowed in adoration. Yes, there are *some* things reverenced in Italy—reverenced by rich and poor, by men and women, by everybody everywhere.

From the cathedral at Spezzia, by the help of the magic Ceterach, a slight transition takes me to the old parish church of Clevedon, where lies buried Arthur Hallam, the talented son of the historian Hallam, and the "A. H. H." of Tennyson's "In Memoriam"—the noblest monument that man's love ever raised to man, on which Mr. Tennyson lavished with the prodigality of boundless affluence the wealth of his intellect, the riches of his soul. We poorer mortals deck the graves of our beloved ones with simple flowers that perish in the using. It was for Tennyson alone to weave undying wreaths, each chaplet bright with the hues of Paradise and fragrant with the breath of love. As we stood by the simple marble slab placed on the grey wall of the old church, we marvelled what manner of spirit had animated the poor dust beneath our feet, capable of playing on the chords of Mr. Tennyson's inmost nature, and of awaking strains of such perfect harmony. As in memory I now recal that hour and the friend by my side, the name of Arthur Hallam fades away and another takes its place; but the beautiful Latin inscription, rendered in simple English verse by a loving hand still reads thus—

"Farewell, thou dearest, best beloved,
Torn from our longing eyes!
May we who mourn thee rest with thee,
With thee together rise."

I may not venture to describe Arthur Hallam's resting-place. We read in "In Memoriam":—

"The Danube to the Severn gave
The darkened heart that beat no more;
They laid him by the pleasant shore,
And in the hearing of the wave."

As Ceterach is in my mind the embodiment of all that is pure and enduring in friendship, so Botrychium lunaria, or the Moonwort (occupying, like Ceterach, a separate niche in Ferndom), represents all that is capricious and unstable. It is not that Botrychium gives you back black looks for your care: on the contrary, it repays you with an appearance of the most felicitous enjoyment. It seems to revel in the change of air; its round little pinnae look fatter; its tiny spike of fruit looks richer. You flatter yourself that at last you have your friend safe; but lo! in the spring when you look for him he is gone—utterly gone. Botrychium can hardly be called a rare Fern, for it has a very wide distribution; but its minute size and peculiar habit render it difficult to find. Its bright green fronds are the colour of the rich meadow land in which in Shropshire, Herefordshire, and other counties it is to be found. In any situation it requires a keen eye to hunt it out. One of its loveliest haunts is on Haldon Hill in Devonshire, where, in the months of May and June, it grows freely on the richer portions of the soil.

When it opens its dewy eyes in the early morning of spring what a panorama of beauty and glory dazzles them! Hills, bright with the green of early corn, sloping down to

pretty farmsteads, nestling in orchards wearing a rosy veil of bloom. Beneath the undulating hills, stretching far away, the boundless expanse of ocean, over which the advancing sun makes a pathway of light; and as he comes up on his royal way, beacon after beacon on the grey range of the Dartmoor Hills (which have been, as it were, a pillow for my Fern), proclaims to the yet sleeping world that the day god has arisen. On the right hand and on the left beauty—beauty of tree and flower—beauty of hill and dale—beauty of rock and river—and beauty exceedingly glorified of ocean, girt on either hand by ruddy rocks boldly advancing into the angry waters or retiring far back, leaving a gentle sweep of bay, where ocean-tossed mariners find rest, and from whence the fisher's boat puts out in safety.

Happy Botrychium, bred up in scenes like this! No wonder you say to yourself when I ruthlessly dig you up with my iron spade (the fibrous roots making a trowel useless), "One woman may dig me up, but twenty shan't make me live." I never have made you live, and I fear I never shall. I treat Botrychium like an annual, and transplant it yearly to the fernery; but I do not care for it. It has but one form of beauty, and that is short-lived, and you see it all at once. It comes up short and stumpy, just where it pleases—it won't be put out. It waves over no broken stone, it adorns no tempest-beaten tree. If you transplant it, it dies; if you leave it, at the first hint of winter it perishes. Often and often I have wished it might be banished my favourite kingdom, and consigned to the land of "Lords and Ladies," to which, in spite of all botany, I believe it more than half belongs.

Ophioglossum grows on Haldon, not far from Botrychium, which it much resembles in its habits. In the lanes leading to Haldon I have found Adiantum nigrum acutum, the variegated Adiantum, a curious variety of Polypodium vulgare, having each pinnae cleft at the end, Trichomanes, Blechnum spicant, &c.; and in the gullies, the giant *Filix* mas, and Lastrea dilatata and spinulosa.

Lastrea thelypteris has also found a home on beautiful Haldon. The spot it has chosen is a green swamp in the midst of the everlasting hills. The fronds make their way through reed and briar up to the fair sunlight, and sometimes will measure a yard and even more in length. Thelypteris is exceedingly troublesome in cultivation from its creeping habit, and I should recommend it to be placed at the back of the fernery, where there would be the greatest amount of shade and damp, and where it would be out of your way. Growing wild, Thelypteris is not without beauty, but in cultivation it has nothing particular to recommend it. The fertile fronds have no decided character of their own, but look like a common frond, ill-grown and faded. Its chief interest is the difficulty of getting it out of its treacherous lurking-place, so green and safe in appearance, so unsubstantial in reality. Bogland abounds in beauty. The Golden Asphodel is there, and the little pink Pimpernel, and there the Sundew lifts up its white blossoms to the early sun; and while you search for these and other treasures, the startled kine turn round and look at you with half curious, half doubtful eye.

Not far from Haldon on the Chudleigh rocks I have found a curious form of Polypodium vulgare. I suspect it to be a permanent variety; and though it is not yet cambricum, its pinnae being narrower and its fructification more abundant, it approaches very near to it in some of the plants; and I look forward to cultivation improving its form and size, which at present is rounder and smaller than the true cambricum, the middle pinnae being the widest.

I found my first wild Osmundas near Exmouth. They grew in an old forsaken orchard, where you took each step in danger of being swamped. The marshy nature of the ground suited these noble Ferns, and they grew up right royally on every side, their fronds waving in the breeze. I never saw more beautiful sunsets than there are at Exmouth. The painter Danby told me he made his home there on that account. He had made long wanderings, seeking for the beauties of the setting sun, and had found the concentration of all he sought for at Exmouth. Shortly after Danby told me this the curtain of night fell on the painter, and his own sun set for ever.—*FILIX-FEMINA*.

[Editors always assume the privilege of correcting evident mistakes in the contributions they receive; and they noticed

in the last communication from "FELIX-FÆMINA" that she had, in the hurry of composition, made a confused statement about *Polystichum angulare* and *aculeatum*; yet the Editors hesitated, and finally refrained from altering what had come from a master's hand. They have had a pat from a velveted hand in consequence, accompanied by the following, to be substituted for the eight lines of col. 1, p. 448, beginning at the fourth line from the top:—

"The Warwickshire lanes abound in *P. aculeatum*. It may be found side by side in its varieties of *lobatum* and *lonchitidioides*, but the latter is more rare. *Polystichum angulare* is also to be found. *Aculeatum* may be known from *angulare* by the darker green of the fronds, by their stiffer habit of growth, and by the prickly nature of the pinnae. It is necessary to study both Ferns together to be able to decide with certainty at a glance which Fern is before you."]

ROYAL HORTICULTURAL SOCIETY.

A SPECIAL general meeting was held on Tuesday, the 13th, to receive the report of the Council on the bye-laws. W. Wilson Saunders, Esq., was in the chair, besides whom there was only one other member of Council present—namely, Mr. Henry Cole, C.B. The attendance of Fellows was likewise very thin.

The CHAIRMAN said they were met together to consider the bye-laws, which, at the last annual meeting, were not considered satisfactory, and the Council at once took steps for their revision. A Committee was appointed for the purpose, and, their report having been adopted by the Council, it was now submitted to the Fellows for approval. They were much indebted to Mr. Thring and Mr. Bowring, who had taken much trouble in the matter, and it was mainly in consequence of their assistance that the Council were in a position to recommend the report for adoption.

As each member present at the meeting was furnished with a copy of the amended bye-laws, they were taken as read.

Mr. CHESTER then said that, incautiously, he had been involved in matters connected with the Society in the spring of last year, and had proposed a resolution requesting the Council to take steps to revise the bye-laws, and the Council had recommended him to be placed on the Committee appointed for that purpose. The position was not an enviable one, and, though he undertook it, he thought it would have been better if some one more conversant with the law had been appointed; and he did not know how the Committee could have accomplished the task without the assistance of Mr. Thring. He would now proceed to point out the chief differences between the new and old bye-laws. He did not say the new ones were perfect, but as much so as the Charter would allow of. In the new bye-laws a very large discretion was given to the Council. He would, however, recommend that body to take early steps for getting a new charter. By the new bye-laws candidates for admission as Fellows were only required to be recommended by two instead of, as formerly, by three Fellows, and these are not required to state whether they know the candidate personally, by report, or otherwise—their simple recommendation to be enough. Further, that the certificate of recommendation shall be suspended in the Council-room, be read at the next ordinary meeting, unless the name of the candidate has been previously published in the Journal of the Society, in which case the reading may be dispensed with; and that the election of the candidate shall be put to the vote at the next meeting, unless the Council sign a certificate recommending immediate election, in which case the candidate may be elected at the same meeting as that at which the certificate is read. Voting to be open or by ballot; in the former case a simple majority to be sufficient, in the latter a majority of two-thirds.

The next alteration of importance was with respect to the subscriptions. Formerly no Fellow more than one year in arrear was entitled to vote and exercise his other privileges; by the new bye-laws no Fellow whose subscription is in arrear is to be allowed to exercise his rights and privileges. Power is also given to the Fellows to remove any one of their body by the vote of a general meeting on four weeks' notice being given, stating fully the grounds on which the proposal

is made. The bye-law permitting the Council to re-admit a Fellow who has resigned to be omitted. With respect to honorary members, the number of which was formerly limited to ten, the number in future to be unlimited. With regard to the annual meeting, instead of being held at one o'clock, by the new bye-laws it is to be at eleven o'clock in the forenoon, or at such other hour as the Council may decide; eleven Fellows to form a quorum as heretofore, at an ordinary general meeting seven. He, Mr. Chester, had some doubt as to the legality of the rule admitting ladies to the right of voting by proxy; but he thought that, whoever he might be, he would be a very bold man who attempted to deprive the ladies of that privilege, and it was therefore continued in the new bye-laws. By the old bye-laws the ordinary method of voting was by show of hands, or calling the roll, when demanded by any two Fellows present, and in certain cases by ballot; whilst by the new bye-laws when the voting was not by ballot, it was left to the Chairman to determine the manner in which it should be conducted. Power was given to the Council to admit the public without payment on any number of week-days not exceeding three in each year. A provision was also now made for the admission of any horticultural societies and their members into union with the Society, and partial participation in its privileges. Section 74 was entirely new—it related to the education of gardeners. Soon after the recess a Committee had been appointed to take the subject into consideration. Sir Joseph Paxton had attended, stated his views, and given much assistance, and the result was that a report was sent into the Council, and, though publicity had not been given to the recommendations which it contained, he (Mr. Chester) believed he might state that it was under consideration. The new bye-law was as follows:—

"At the first meeting of the Council after the annual general meeting in each year, the Council shall appoint a Committee to be called the 'Education Committee,' whose duties shall be to advise the Council what measures they can take for improving the education of gardeners, and to assist the Council in taking such measures as the Council may approve for that purpose. One-half at least of the members of the Education Committee shall be members of the Council for the time being; and the Council at its discretion may from time to time appoint, remove, re-appoint, and vary the number of the members of that Committee."

Sections 82 and 84 provided that

"Any member of the Council may resign his seat to the Council, but such resignation shall not be deemed complete until it has been accepted by a resolution passed at the next ensuing annual general meeting, and the acceptance of any such resignation shall not be entertained by such general meeting unless the member proposing to resign has signed a paper in the form marked E in the Appendix, and has left it with the Secretary or Assistant Secretary on or before the 1st of January preceding such annual meeting."

"If any member of the Council dies, or becomes incapable from any cause whatever in the interval between any two annual meetings, the other members of the Council may fill up the vacancy so created by the appointment of some other discreet Fellow, and any Fellow so appointed shall for all purposes be deemed to occupy the position of the person to whose seat in the Council he has been appointed."

This was intended to prevent objections being raised to the validity of elections, as was the case at the last annual meeting, and, to prevent the possibility of doubt, notice of resignations was required in a particular form. The question which then arose was whether a resignation was to be taken as one of the three vacancies, or as being in addition to these. He himself thought the latter ought to have been the way; but this was only an instance of the difficulties with which the Committee had to contend, in consequence of the Charter and old bye-laws; and had it not been for the assistance of Mr. Thring they could have done nothing with the mass of confusion which existed, but by his aid they had succeeded in drawing up a clearer code of law to govern the Society. It was also thought desirable to introduce a bye-law to the effect that "no member of Council shall, at any exhibition of the Society, receive any money prize, medal, or pecuniary reward for any article belonging to him, or to any firm of which he may be a member, or in the profits of which he is interested."

The Committee had likewise proposed some alterations in the form of the balloting paper—[That the Council shall cause to be prepared, on or before the 15th of January in each year, two balloting papers, one stating the vacancies (distinguishing ordinary from extraordinary vacancies) created or expected to be created in the Council, and required to be filled up at the annual meeting; the other containing the names of such Fellows as the Council recommend to fill the offices of President, Treasurer, Secretary, Expenses Com-

mittee-men, and Auditors ; these balloting lists to be circulated amongst the Fellows some time not later than the 15th of January. Further, that if any Fellow desire to substitute the name of any other Fellow for that of any one recommended by the Council for removal or election, such Fellow, within seven days after the balloting lists have been circulated, shall leave at the offices of the Society notice in writing of every such proposed substitution ; that the notice of any substituted names shall be suspended in the Council-room, and circulated in or with the number of the Society's Journal published in February ; and that if any balloting list contain any names other than those in the list recommended by the Council, or of which notice has been given in the prescribed manner, or if it contain more than the proper number of names, such list shall be deemed void, and not taken account of by the scrutineers.] The object of these provisions was to put it out of the power of a small body of the Fellows to determine on names beforehand, and so take the Council and Society by surprise. Last year the changes were only known in the Council, but by the proposed alteration Fellows would know what the composition of the Council was likely to be, and could deal with it. Thus there could be no surprise on either side—either on that of the Council or that of the Fellows.

With regard to the accounts, the new bye-laws provided for a report from the auditors.

Mr. Chester, in conclusion, suggested that this did not appear to be the occasion for criticising the position of the Society, although he believed that it would be competent for the meeting to do so, and he wished to impress upon the Fellows the importance of making as soon as possible any alteration they might think fit. He begged to move that the existing bye-laws be repealed, and the new ones adopted.

Major-General Sir ANDREW WAUGH, in seconding the motion, said that their thanks were due to the Committee and Mr. Chester for the pains they had taken. It appeared to him that the general principle which had guided them had been to give ample power to the Council, who were themselves responsible to the Fellows.

Mr. S. H. GODSON thought the new bye-laws should stand over for further consideration; if gone into *seriatim*, they would take two or three hours, and seeing the few members who were present he would move an adjournment for a month. He had stood alone in the Council on many matters, and that was not an enviable position. He had, though a member of Council, applied to see the accounts, and had been refused, and that was the reason he was standing on the floor merely as a Fellow of the Society, and not sitting with the honourable gentlemen up yonder, for in consequence of that refusal he had sent in his resignation to the Duke of Buccleuch, the President.

With regard to the new bye-laws they had been nine months at least in the hands of the Committee, and it was not too much to ask that they should stand over another month. It might be asked why he himself did not take an active part with respect to the revision of the bye-laws? and his reply was, that he was not on that Committee, though he should have been, had not Mr. Cole objected to it. There were several things in the new bye-laws to which he took exception; for instance, if, as was the case with Sir Daniel Cooper, their Treasurer resigned, they had no power under the new bye-laws to appoint another. He objected to the Council having more power than they already possessed. Had one member of Council the power of preventing another seeing the accounts? He was referred to Mr. Cole for permission to see the accounts.

The CHAIRMAN said he ought to state that he never knew Mr. Godson had applied to see the accounts and been refused.

The ASSISTANT SECRETARY said Mr. Godson must be under some extraordinary delusion. Mr. Godson had never asked to see the accounts. Mr. Cole had left some papers of his own, and he would not take upon himself to let Mr. Godson see them without Mr. Cole's consent being previously obtained.

Mr. COLE said if he did leave a paper, he had never refused Mr. Godson's inspecting any accounts. He (Mr. Cole) had left a paper at the garden with memoranda of accounts, and Mr. Murray (the Assistant Secretary) was under the impression that Mr. Godson's application referred to these, and not to the books of the Society.

Mr. GODSON—Very prettily put.

Some further remarks were then made, when Sir Andrew Waugh rose to order.

Mr. GODSON—I speak on the question of resignations. Under the new form of the bye-laws supposing a Treasurer to be appointed in the interval between the annual meetings, the appointment would be illegal, and all cheques signed invalid. He hoped that the mover and seconder of the motion before them would consent to an adjournment for another month.

Sir ANDREW WAUGH—if Mr. Godson had any objection to any of the bye-laws he might propose another, and they could debate it.

The CHAIRMAN—if Mr. Godson will move an amendment that would be the quickest way.

An amendment was then moved and carried—that any casual vacancy by death, resignation, or incapacity, should be filled up by the Council.

Mr. GODSON continued that a greater latitude was given to the Council than before. He would suggest that the whole of the names in the Council should be returned to the annual meeting, which would give the Fellows at large the opportunity of striking out any three, and that thus the Fellows would have the control; by the opposite course the power of introducing fresh blood would be nullified.

Mr. THRING regretted that it was utterly impossible to carry this proposition into effect. It would amount to ostracising; and he thought the proposed bye-laws only amounted to this—that the Council should have their list, and the opposition theirs. They might then fight it out fairly.

Mr. GODSON—Nothing could be more explicit than the old rule; but he told the Assistant Secretary again, that at the last annual meeting the resignations were given in previous to the election, because they were on the minutes of the Council. [“Time, time.”]

Mr. GODSON—“Time!” He was much obliged to that gentleman who called “Time.” He always tried to be in time; he was generally five minutes before his time; he was too soon for this meeting; he had been waiting for it ever since half-past twelve o'clock last night. The notice in his Journal was for 2 A.M., and he would have come there at two o'clock in the morning had not some friends persuaded him not to do so.

The ASSISTANT SECRETARY here said that Mr. Godson had a proof-sheet, and that was not the notice.

Mr. GODSON asked for the notice convening the meeting. It should have been read in the first instance.

The ASSISTANT SECRETARY said it was in the “Proceedings,” and in one of the papers.

Mr. GODSON called for the notice.

Whilst the paper was being sought for, a Member thought there was a bit of quiet satire in bye-laws 81 and 83, by which it was provided that vacancies should be filled up by “discreet persons.” He thought it would be better to assume that all were “discreet,” and strike out the word. [Laughter.]

The CHAIRMAN then read the notice, published in THE JOURNAL OF HORTICULTURE of December 6th, convening the meeting.

Mr. GODSON—What paper are you reading from?

The CHAIRMAN said it was THE JOURNAL OF HORTICULTURE, one of those papers which are very well known, and circulate largely among horticulturists. Its circulation was as large, if not larger, than any paper of its kind, and horticulture was much indebted to it.

Mr. GODSON—And this Society has much to thank it for.

Some discussion then took place as to proxies; and Mr. THRING proposed that Any Fellow holding proxies shall vote as such at a ballot, by annexing by whose appointment the proxies are given.

After some further discussion, it was moved by Mr. CHESTER, and seconded by Sir ANDREW WAUGH, “That the existing bye-laws be repealed, and the new ones adopted, with the alterations, amendments, and additions thereto;” and, this being carried, the same gentlemen moved and seconded, “That the meeting recommend the Council to take steps to get a new Charter.”

Mr. GODSON said they had not £300 to spend on a new Charter.

The CHAIRMAN said the present Charter had been a stumbling-block in the way of the Society, and, on putting the resolution to the meeting, it was carried.

A vote of thanks to Mr. Thring, and the rest of the Committee on the bye-laws, was then carried unanimously; likewise a vote of thanks to the Chairman, Mr. Godson, in moving it, passing a high eulogium on the forbearance of the Chairman, than whom, whenever he occupied that position, no one could act with greater fairness.

DESTRUCTION OF THE INSECT SCALE.

I DESIRE to draw your attention to a discovery my gardener has made, for even if known before, I have never found it alluded to in any horticultural work, and on looking through your past volumes they throw no light on the subject. I allude to the scale on Orange trees.

I have a small Orange-house, in which I grow all the varieties at present in England that are good for the table, and until this year I have been enabled to keep the trees free from scale, or, at all events, so clean that a winter cleaning alone was sufficient. I always have heat in this house, and this season in the month of August (the early part of it), they were so dirty that my gardener took each tree out of the house, and they were cleaned most thoroughly. It was done by a small rose I had made for red spider on Peach trees under glass. I have a pressure of more than 100 feet of water, and its force immediately removed every scale, and when replaced in the house it would take ten minutes to find one scale. To my own, and my gardener's utter astonishment, the trees soon became as dirty as ever, the scale breeding nearly as fast as aphides. As I was going from home, I requested my gardener to do nothing with all hands until he had again thoroughly cleaned the Orange trees, as it really amounted to this: they must be kept clean, or their culture relinquished. With clean water, small brushes, and sponge, they commenced, and when I returned I found the cleaning not half finished; the insects were so numerous, that the time absorbed, with the greatest industry, was immense.

On my return, my gardener said, "I have found out how the scale breeds, and can account for their rapid increase. Last year we had some aphides in the house, and from several times fumigating we had little or no scale. I found a number of small black insects running over the Orange trees, and on those cleaned the day before they were as numerous as on those not cleaned." We at once fumigated and but slightly, and found it killed every insect. He then commenced examining some full-grown scale having a dark spot in the centre of the scale, with a magnifying glass. He found under the scale, in different stages, the identical sort of small black insects he had seen on the trees, and killed by smoke. He preserved some in a bottle for me to see, and he drew the conclusion that this is the male, the limpet-shaped scale the female, and that if you by regular fumigating kill the male, there will soon be no scale. This, I believe, to be the true version of the increase of scale; but to be certain there was no mistake, I found numbers of large scale on trees not yet cleaned, and with a magnifying glass in hand, I removed with a pin the female scale, and there found numbers (one under each scale) of the small black insect. I have found in books on the subject, since then that this is the male and female scale, but I have not found it in any horticultural work, or any suggestion, that the male is easily killed by smoke, and if you destroy them you certainly must prevent any increase.

I enclose you leaves with scale on them, and the male in different stages of growth, also some perfect ones, taken running about on the trees, and some from under the scale (in a small bottle). I have often removed the female scale when large and full grown, and with a glass seen hundreds of small ones run away, but I could never account for impregnation.

Because I have had so much scale on my Orange trees you must not imagine my place is not kept clean, as I can show Peaches of all kinds, fruit trees of all kinds, under glass and exposed, vineyards, &c., as clean as any in England. I should be glad of your reply, and you may make any use you like of this communication, but I am convinced, as an

old florist, that we have hit on the way to destroy scale, and hope it will afford as much benefit to others, as I fully expect to find myself. It also shows why Orange trees kept out of doors in the summer get clean of themselves, there is not continuous heat enough to bring the male scale to perfection, and if it hatch the cold nights either kill him or prevent impregnation. Mr. Rivers whom you know to be a very experienced man in these matters, finds it an entirely new light to him.—JAMES ALDRIDGE DEVENISH, *Rodwell, Weymouth.*

[We forwarded this communication and the specimens to Professor Westwood, and he replies thus:—"The preceding communication is another instance of investigation in the right direction not carried quite far enough, and, consequently, resulting in the not unusual error of friends being mistaken for foes, and beneficial insects destroyed instead of the real authors of the mischief complained of. The small, black, lively insects sent by your correspondent, and regarded by him as the male of the scale insects, are not such, they are parasites belonging to the order Hymenoptera, and genus Encyrtis, which feed in the larva state within the bodies of the scales, and, consequently, destroy them. Hence they are to be preserved and not destroyed. The real males of the scale insects are, as described in all works of entomology, and I presume also in all good horticultural works, minute, weak, six-legged, two-winged creatures, slow in motion, with the bodies and wings clothed with a fine white powder. In out-of-door species of Coccidae these males are developed at a fixed period of the year, and as they are very fragile they might be easily destroyed by fumigation attempted at the right time. In hothouse species I believe the generation of scales and allied insects is continuous, and that there is not a fixed time for the development of the males; but this fact is not proved. Investigation, where scales are prevalent, will easily determine whether this be so or not. If the males should be proved to be produced at one or two fixed periods of the year, there will be no excuse for the horticulturist if he do not clear his houses by destroying the males, and so preventing the production of future broods of young.—J. O. W.]

EARLY PEAS.

(Concluded from page 467.)

Of the ordinary modes of sowing and planting Peas for an early crop, it is needless to say much, as they have been frequently detailed to the readers of THE JOURNAL OF HORTICULTURE. In general, the middle of November is as early as is prudent, under any circumstances, to sow a crop, and very often this is too early, a mild autumn or winter encouraging growth till the plant is so far advanced as to be unable to withstand the spring frosts which follow, so that it is generally better only to sow a small quantity at that time, and make another sowing early in December, following this up by one early in January. This is the mode we adopt, but Mr. Fish, our worthy coadjutor, prefers deferring sowing till spring, and then he does so in pots or boxes, and plants the crop out after hardening off in the usual way. We have adopted both plans with much the same result, and where there is a difficulty in saving the autumn-sown crops from the attacks of slugs, mice, and other predators, as well as when there is some drawback in the ground, it is better to rely on spring sowing and planting out; but when any approach to uniform success can be depended on out-door sowing is a much less troublesome mode, as the earliness of the crop in each way is so nearly alike, that it would be difficult to say which is the better.

The preservation of the seed from mice and birds, and the young plants from the attacks of slugs and smaller enemies, are also matters worthy of attention. Covering the row with coal ashes is not by any means a bad plan, but they ought not to be fresh from the fire, otherwise they are prejudicial to vegetation. A covering of sawdust is also beneficial, as mice do not seem to like burrowing in that material, while better than either as a preventive of the attacks of slugs, is barley chaff, which attaches itself to, and lacerates the soft bodies of the slugs, and does not seem to be at all relished by mice.

The attacks of birds, however, are not so easily prevented,

and netting has to be adopted in some places; the simplest and easiest protection is a length of galvanised wire netting about 18 inches wide, bent in the middle so as to present a continuous arched covering. In some gardens these and similar contrivances have to be put in requisition to secure a crop in summer, the birds being so troublesome, and they are equally so when the crop is fit to gather.

It is seldom that the early crop requires any further shelter than what the ashes, sawdust, or chaff alluded to supplies, but as soon as the plants have grown 6 inches high, or even before that time, some short stakes may be of service in protecting them from the effects of cold winds or late spring frosts. I have seen coverings for early Peas and Potatoes made like the ridge of a house, about 18 inches wide, and the same high, transparent calico, or some such material being stretched over them, and which could be put on and taken off when wanted, and they were of service to the Potatoes; but the Pea is a much hardier, though not by any means so robust a vegetable. In cold, bleak situations, however, shelter of some kind may be of service, and in such the crop may receive its proper staking earlier than in places more favoured.

Of the varieties of early Peas much has been said and much disputed. The multiplication of names has been such that it is much to be feared that several so-called early varieties, have a common origin in a bag of Charlton, the only difference being the name and the higher price. Now, I by no means charge respectable seedsmen with intentional fraud—on the contrary, many, I know, are amongst the most honourable traders of the community; but there are others less scrupulous, who, though their stock be but limited, yet, somehow, have always everything that is asked for, and a bland excuse for everything that comes different from what was expected; but buyers, as well as sellers, are to blame for this. The insatiable thirst after fresh names must be met, and scope is given to those whose scruples do not prevent their benefiting by it, and, though new and popular varieties of Peas, as well as other vegetables, may be decidedly better than some that preceded them, it unfortunately happens that every parcel bearing that name is not the true variety. However, a few years generally consign all indifferent varieties to oblivion—thus the popular names of ten years ago are but rarely met with now, while the standard old ones, as the Kent, Charlton, and Early May, which, by-the-by, I believe all very nearly resemble each other, are still on the lists. Nevertheless, as improvements are wanted, let us hope that further progress may yet be made. In the meantime I give a short list of such early varieties as I am acquainted with:—

Daniel O'Rourke.—A good Pea; stands the winter well, and a tolerably good bearer. Sangster's No. 1 is the same as this.

Warner's Emperor.—Of late years this Pea has become more tender with me than it used to be; it is, however, very good still, and, amongst early Peas, none is more prolific.

Dickson's Favourite.—Somewhat taller than the above, being more in the way of Prince Albert, and I believe Omar Pacha is somewhat the same in habit; with me it did very well last year.

Early Warwick.—This old variety has so strong a resemblance to the Charlton that I think they must be classed as synonymous.

Racehorse.—I have never seen this in good condition, and I find the name is rare in seed catalogues.

Early Frame.—This, the Early May, Kent, and some others, have doubtless taken their origin from the Charlton. They are all good bearers, and about the same in earliness as those previously mentioned.

I must confess that these are the only early kinds I have grown of late years, and many kinds are no doubt omitted which, by other growers, may be regarded as superior to any I have named. Amongst those I hear spoken well of is Sutton's Conqueror, very good as a running Pea; and there are some of the dwarf section, such as Dillistone's Early Prolific and Tom Thumb which have each their admirers. Doubtless there are others of equal merit, but, not having grown them, I cannot speak from my own experience. Early Peas, however, are of such importance that it is not likely that any really good ones can remain long unknown. The great aim seems to be to obtain varieties that will

come into use a few days sooner than those already known to us. Constitutional hardiness is another qualification; for it sometimes happens that considerable portions of a row die off in March, from causes which are but imperfectly understood. I have in vain endeavoured to determine the cause of this, though it is likely that the plant dies when it no longer receives any support from the seed; but I am far from affirming that such is the true cause, as the season is generally so far advanced as to lead to the belief that the seed had long ceased to afford nourishment. Certain, however, it is that everything connected with the Pea is not yet fully understood; and I confess being as anxious to learn more on this subject as to give advice. Common as the Pea is, and its culture under certain conditions more easy than that of most other crops, there are some points connected with its management in winter, as well as in the latter part of summer, which render it anything but a certain plant. On its summer growth another article will be forthcoming at an early period.—J. ROBSON.

ANEMONE APENNINA CULTURE.

In reply to "E. F." who complains of the flowers of her Anemone apennina plants being "poor and puny," I may state that we have plants of it in large patches in a border amongst other herbaceous plants that have no flowers less than a half-crown piece, and many fully the size of a crown piece. The border runs east and west. At the back (the south side) there is a row of variegated Hollies and other shrubs from 10 to 15 feet in height, in front of them are tall herbaceous plants gradually lowering in height from the back to the front, which may be about 8 feet from the Hollies and shrubs. The border is, therefore, fully exposed to the north, and partially so to the south; for the shrubs shade the border considerably, yet not completely, for they are not planted close together, but so that each may be seen, and worked about on all sides. In this border, about a foot from the Box-edging, the Blue Wood Anemone is planted now in patches a foot or 18 inches in diameter, with room between each for hoeing and otherwise trimming the border when necessary. In this border, shady during the mid-day hours only, in a light loamy soil on gravel, this plant is quite at home. It has no rival when in flower, and even before blooming its handsome foliage renders it particularly attractive. It receives no care beyond keeping clear of weeds, and the intrusion of its neighbours, and lightly pointing the ground around it in autumn or spring.

A calcareous soil is the most suitable for it; but it will grow anywhere if the soil is free of stagnant water, and not very strong. The situation should be open yet shady—that is, not so shaded as to be hidden from the sun's rays by a close canopy of leaves overhead, nor dried up through the trees abstracting all the moisture and nutritive principles from the soil, but what may be termed open woods and borders shaded from the mid-day sun, on the borders or margins of which it will grow freely, especially if the soil is naturally light and dry, and not rendered so by the roots of other plants. The ground should have a dressing of leaf mould 3 inches thick worked in to a depth of a foot, and the roots should be planted in this in August or September about 3 inches apart, and covered an inch deep with soil. In November the surface should be mulched with an inch of leaf mould; and here they should be allowed to remain for the next three years at least without being disturbed, keeping them clear of weeds and other plants that may intrude upon them. If the part of the garden is kept as dressed ground, a slight forked around them twice a-year will not injure them, providing care be taken not to disturb them, and if a little leaf mould be forked in each time the fork is plied round them the flowers will be much finer.

Once planted and established nothing further will be required for years, and the plants will go on increasing, in time forming large masses, which when in a sheet of bloom, as I have seen them amongst some trees surrounding rock-work not many miles from York, cannot fail to cause admiration. It is a scarce plant in gardens, and in the trade, but ere long we shall have such plants as these offered by the hundred, and in time our parks, our woods, and woodland walks will present a scene of interest and beauty that will

vie in spring with the more costly flower garden. The time will soon come when our parks, our woods, and our woodland walks will be ornamented with such plants as the Snowdrop and Aconite in winter; Crocuses peering on their margins, and on mounds; Daffodils decking the pastures and making them yellow, as if strewn with Buttercups; Primroses and Cowslips adding their charms. Crowfoot and Orchises will be in the hollows of many meadows, and most woods, as well as the common Wood Anemone, the Violet, and very many more, all in place of Nettles, Thistles, and other rubbish, for which such places are now so conspicuous. That the walks in woods will soon be made fit for the foot to tread upon once more, that employers will see that such places are not robbed for the sake of sensation gardens, and that there will be a return to things purely horticultural, is the firm conviction of—G. ABBEY.

BIRMINGHAM FRUIT AND CHRYSANTHEMUM SHOW :

OR, THE HANDSWORTH HORTICULTURAL SOCIETY.

FROM what has been written of this Society from time to time, we might have been led to believe that it offered fair for a Midland Counties Exhibition. Than Birmingham no town could be better chosen, and no time more wisely selected than the week of the Cattle and Dog Shows. It is worthy of remark that whilst a horticultural society seems to be maintained with difficulty, a Cattle or Dog Show whenever attempted meets with every success, and the rush of visitors is something extraordinary. We have been so long used to a cattle show, that we do not now wonder at the fittings and preparations for these occasions. A dog show is of more recent introduction, and who could visit this show at Birmingham without feelings of admiration? A building to all appearance erected for the express purpose, beautifully fitted up and subdivided for the accommodation of the different classes of animals, and even abundantly heated by the introduction of gas—a multiplicity of dogs in every class, clean, and well cared for—at one end of the building a magnificent display of silver cups for distribution amongst the successful competitors—all this showed strength and a healthily-conducted exhibition.

We do not find in the Cattle and Dog Shows such restrictions as to the locality of the subjects for exhibition as we do in the Horticultural Show. The two former are most liberal, and have acquired a fame worthy of the great town in which they are held; the latter is remarkable for its being so extremely two-sided. The Class No. 1 limits the competition of fruit to that which is grown within fifteen miles of Birmingham; and Class No. 2 is open to all the world. Thus an English gardener who wishes honestly to compete for any of these prizes, pits himself against others who get up their collection out of a garden in size nothing less than that of the whole world. I am inclined to think that before this Society can claim to itself much credit for being the cause of advancing the "science of horticulture more than any other provincial one" (as stated by one of your contemporaries), an infusion of much new blood will be required. I had a schedule sent me which I took for granted was an invitation to compete, but on looking it over I found that in Class No. 1, I was precluded from the simple fact that I was beyond the restricted radius of fifteen miles. On reference to Richmond's new map of the Midland Counties, I am about twenty miles from Birmingham, as the crow flies. Referring further to this class, there were no prizes for Pine Apples, or single dishes of Grapes, which at this season of the year are very interesting. Then, again, for a collection of twelve dishes of fruit, a prize of 30s. is offered. This is the highest prize in this class. A goodly sum for such a boastful Society. This Exhibition, be it remembered, is open for four consecutive days during the great show week, and is afforded the use of the "noble Town Hall granted by the Mayor," yet the total amount of prize money, including the ten-guinea cup, does not amount to £100. How does this small amount contrast with the reported account that "several thousands visited the Exhibition during the four days?" This is the amount which does so much for the "science of horticulture." It seems strange that a medium cannot be given between on the one hand, a radius of fifteen

miles round Birmingham, and on the other the ends of the earth! The true gardening skill of this country is not encouraged or represented by the Handsworth Exhibition. We do not find such restrictions and extremes in the Cattle or Dog Exhibitions.

I next had a glance at Class No. 2, open to all the world fruiterers, dealers, and others. The bye-laws of this class say—"It is not imperative that the fruit shown in this class should have been grown by the exhibitor." This piece of cookey jobbery would not do for me—pardon me for thus expressing myself, but to me it seems too plain, and I cannot help it. If I were to compete in this class, having a view to success, I would have to journey or telegram, to beat up a collection. Thus, without even the shadow of a garden, without even seeing a single fruit necessary for any of these collections for fifty consecutive weeks prior to the Show, may any one with a very ordinary amount of sagacity, purchase or obtain by any similar means, all that is required, and he who is most assiduous by these means in obtaining the ten-guinea cup, will, according to this Society, be the one who has contributed most to the advancement of the "science of horticulture," without requiring to take any pains as to culture, watering, budding, grafting, root-pruning, and a thousand other cares. A man following any occupation in kin as different to gardening as a lobster is to a skylark, may, by means of "purchase, put himself in a superior rank to those who have laboured indefatigably in the trenches for twelve months."

Societies are generally organised through the exertions of some enterprising individual, and generally prosper when they have for their object the common weal of his country and fellow men, and with such philanthropic views that individual is much to be admired. I do not profess to know who are the actual managers of the Handsworth Society, but from a report which has appeared in this Journal, for its admirable arrangements much credit is due to the Honorary Secretaries, Mr. George P. Tye, and Mr. Charles James Perry, the latter maintaining throughout the play a position resembling very much that of a "Hamlet." It is indispensable to have a good Secretary for the management of a Society, and few positions could offer better to show the philanthropy of a man than that of an honorary secretary giving his services in such a way as not to invite the remark that those services are for any selfish end. At this Show we find the Honorary Secretary, a resident near Birmingham, competing for, and carrying off the ten-guinea cup, and all the rest of the principal prizes, obtaining twelve first prizes and four second, walking easily over every one, including Mr. Pluck, a fruit merchant of Jersey, a resident among the fruits in the Channel Islands, and to whose name we only find one first and two second prizes recorded. It seems strange that Mr. Pluck should send fruit all the way from Jersey, and compete only for one or two secondary prizes. The large collection of fruit of Mr. Perry's which did obtain the cup, contained a tolerably free sprinkling of baking and stewing Pears. Mention of this, however, did not appear in any of the reports of the meeting which I saw.

It will be necessary for the Handsworth Horticultural Society, professing to do so much for the "science of horticulture," to give a public explanation as to the cause why they limit their encouragement to fifteen miles round Birmingham on the one hand, and on the other why they invite competition from all parts of the world. These extremes without some explanation are not reconcilable, and until this is done, the Birmingham Fruit Show will remain a delusion.

A thoroughly healthy horticultural society is much wanted in Birmingham, not only for the Midland Counties, but for the north of England, Scotland, and Ireland. Many gardeners at this season could bring their productions to Birmingham, who could not go so far as London, and on this account their produce, no matter however meritorious, would never be brought before the public. There is yet a wide field open for the encouragement of horticulture. The Royal Horticultural Society of London enjoys a great name, but is exceedingly local in its efforts to do good. Those who reap the most benefits from that Society are the London nurserymen, and suburban gardeners, whilst the encouragement of provincial nurserymen and country gardeners is comparatively neglected. But now that they are fairly

started (?) we find them desirous of having union with local societies, and what is to prevent them from putting their shoulder to the Birmingham Society, and issuing a schedule for a great fruit show to be holden once a-year during the show week? It might, however, be necessary to depute from the Fruit Committee a certain number of delegates to insure success and protection to the meeting.—WM. MILLER.

CHARLES LEFEBVRE ROSE.

AMONGST its other claims to be considered the finest Hybrid Perpetual Rose in cultivation, may be added, if my experience of it be correct, that of really deserving the name of Perpetual. I have this day (December 8th), cut a bloom of it, which for size, shape, and colour is as perfect as if cut in the middle of the Rose season. It measured 5½ inches across, and is, as I look at it on my chimneypiece, a rich treat at this time of the year. Undoubtedly this is an exceptional season, but I think there are few Roses of which such an account can be given now. You may get them, it is true, but not in such character.

I know it is the habit to decry Perpetual Roses, as if they did nothing worthy of their name, but to have had, as I have had, blooms for so many months, up to midwinter, surely entitles them to some credit on this score. If persons expect that their trees are to be for ever crowded with bloom as in summer, of course they will be disappointed; but if their expectations are moderate, I do not at all see that the name is undeserved, and it is just possible that improved varieties, with somewhat more of Bourbon blood in them, may yet give us more autumn flowers than even at present.—D. Deal.

DESTRUCTION OF RED SPIDER.

SOOT is a certain cure for red spider. No plant, that I know of, is more subject to them than Kitley's Goliath, a much better Strawberry than has ever been allowed. I have reintroduced it. It is better than many that come out at high prices. It is obtuse-coned, subject to white tips, but fine, a heavy cropper, and of good flavour. Red spider drove it out of general cultivation. Some years ago I had some plants sent to me to plant covered with them like Cayenne pepper. I put in the plants, watered them and the whole surface of the ground, and then I put on the soot till nothing but soot could be seen. I never saw anything more of the red spider. My present Goliaths are perfectly free from this pest. In two places I have seen Goliath perfectly devoured by it. Perhaps soot mixed with the sulphur and clay might be of service to the fruit trees of "G. W." (page 472). Insects detest ammonia, and in no form can you apply it so innocently as with soot, which containing nitrogen is conducive to the prosperity of vegetation. When sown over Strawberry plants it enables them greatly to resist severe frosts. —W. F. RADCLYFFE, Rushton.

CRUSHED BONES AS A MANURE.

I SHOULD feel obliged by any of your correspondents stating if any injury has arisen to their plants by the use of crushed bones. Mr. Rivers, in his "Orchard-House," recommends the use of one quart of bones to every potted Vine, mixed intimately with the soil; and, in your answers to correspondents, I see them recommended to be placed near the bottom of the pot. Now, I had some nice young Vines last autumn, two years from the eye, intended to fruit the present season, which were healthy and well-rooted when potted, and to which I applied about one quart of fresh bones, crushed, mixed with the soil, and I expected good results. From about ten such Vines I have not had a bunch; they have grown very badly, and have not ripened their wood. Satisfied that something was radically wrong, I examined their roots, and found them very poor and rotten, and some roots, as thick as the stem of a pipe, which look healthy, are in some places shrunk to half their size, and at such places they easily break.

My sister, also, hearing of the virtues of bones, used some for her Fuchsias, which have done pretty well; but, on repotting, she finds very few roots, whilst, in other seasons,

without bones, the soil has been one complete mass of roots.

My opinion is that the bones have generated some fungus or other in the soil, which has produced the effect described. Favour me with your opinion, and say should the bones be raw or boiled, or vitrified. —J. J.

[A quart of crushed bones we consider quite enough for a bushel pot. Using raw bones extensively has just produced the same effect as using putrifying flesh in the soil. Boiled bones, or old bones, may be used more freely. Vitrified bones, as superphosphate of lime, may be used safely in moderation, and best as a top-dressing—say 2 ozs. at a time to a 15-inch pot. We, too, have been thwarted once or twice by using raw fresh bones. If unavoidably used they should be placed in the soil at some distance from the roots.]

VINES IN AN ORCHARD-HOUSE.

I SEE one of your correspondents does not agree with me on the value of the Trentham Black Grape for a cold house, and says his plant does not set its fruit well. I have two bearing-canées of this variety, one in a warm house and one in an orchard-house without fire heat. From the first we gathered about 40 lbs. weight of beautiful fruit, as well set as Black Hamburgs, larger, richer, and thinner skinned, and it has been quite as satisfactory in the two previous seasons. I know it to be correct, having had the plant direct from Trentham. As I wrote before, it was in every respect superior to Black Hamburg in the cold house.

Now, as both of our houses have a good deal of air given to them, is it not possible that your correspondent's house may have been too close and damp? There must be some reason if we could but find it out why Vines behave so differently in one place to what they do in another. Ask a man whose soil is dry and who gives a great deal of heat to his Vines, what he thinks of Barbarossa, and he will, perhaps, tell you it is the best of all late Black Grapes. We all know what it is as generally seen. So of the true Black Alicante. I have grown it for years in two houses, one warmer than the other. In the warmer house it is equal to the Lady Downes' and keeps better; in the other, which had heat enough to ripen Black Hamburgs thoroughly in October, it is hardly fit to eat, though quite black and equal in appearance to those in the warm house. There is much to learn about fruit; let each give his opinion and the reasons for it, and it will be mutually beneficial.—J. R. PEARSON, Chilwell.

CHRYSANTHEMUM "BOB."

Two gardeners here in New York had a dispute about the date when Chrysanthemum "Bob" was first introduced, raised, or sold in England. The one contends that it was cultivated in England in 1850, the other says it was not out at that time. Will you oblige us by answering the above.—J. W. WOOD.

[We sent the above letter to the best authority we know on all that relates to the Chrysanthemum, and the following is his reply:—"Bob was raised by an English florist at Lyons, named Smyth, about 1852. I sent it out in 1854.—JOHN SALTER, Versailles Nursery."]

CHILDREN'S CHRYSANTHEMUM SHOW.—A Chrysanthemum Show on a small scale, took place at the school-room of Summer Town, near Oxford, on Monday last, the exhibitors being the children educated there. With the view of fostering a love for flowers amongst the children, one hundred young plants were distributed in the spring to about thirty of them, boys and girls, by a late resident (Professor J. O. Westwood), the only restriction being that the children undertook to cultivate the plants themselves without assistance. Small prizes were offered, not so much for fine flowers as for care bestowed on the plants. The late dry summer proved unfavourable for the experiment, but seventeen of the children produced their plants on Monday last, to nine of whom prizes were accordingly given; several of the plants being carefully trained and nicely bloomed. The girls appeared to have bestowed as much pains on their plants as the boys.—(Oxford Journal.)

CULTIVATION OF THE MELON.

(Continued from page 413.)

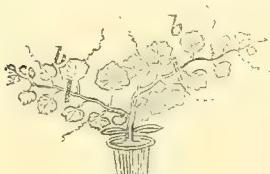

MELONS IN HOUSES.

Fig. 16 shows a plant in a six-inch pot with two rough leaves, and a pair of seed-leaves, and which is ready for stopping.

*Fig. 16.**Fig. 17.*

Fig. 17 represents the same with the growing point rubbed off, or taken out with the point of a penknife, at the second rough leaf. Any shoots coming from the axes of the seed-leaves are to be rubbed off when first visible.

Fig. 18 represents the plant with two shoots springing from the axes of the two rough leaves to which it was previously stopped. If the plant have a six-foot trellis to grow on, these two shoots will be sufficient, and they may, therefore, be trained to the trellis without stopping, at 1 foot apart, taking out the first three side shoots that spring from the bottom of each of the principal shoots with a small pointed sharp

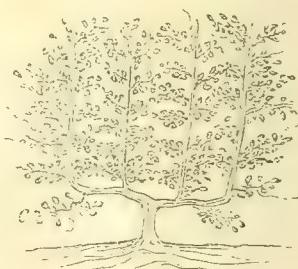

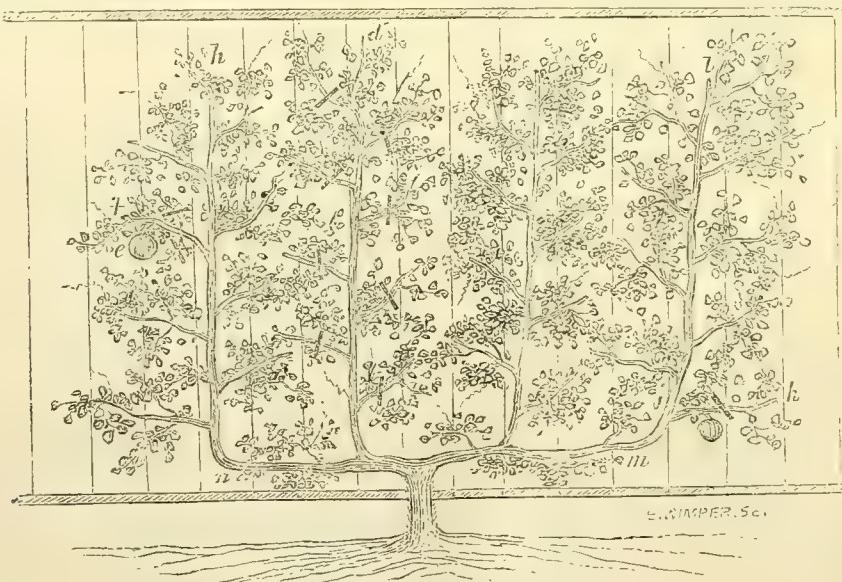

*Fig. 18.*

knife. Thus taking away the side shoots near the collar of the plant secures light and air at that part, and decay there, which is a common disease, is to a certain extent prevented.

If three or four shoots be required to cover the trellis, at the distance of a foot apart, the two shoots are stopped at the third leaf (*b*, *fig. 18*), and this will give rise, generally, to six shoots, but always to four; and of these, four shoots should be trained up, at 1 foot apart, from the bottom towards the top of the trellis, and if two more be produced, they also may be retained, and kept at the lower part of the trellis, and stopped pretty closely, to act as a reserve in case the principal shoots fail to produce fruit.

The requisite number of shoots to cover the trellis being obtained, whether that number be one, two, three, four, or more, they should be trained straight without any further stopping until they reach to within 6 inches of the top of the trellis, when the point of each should be taken out with a penknife, for large cuts at any time always weaken the plant. Taking out the points of the principal shoots will cause the emission of side shoots, which I will term laterals, all along the principal shoots, and from these, at the axils of the second or third leaves, fruit will usually appear. Should any, however, not show fruit at or before the third leaf on the lateral, such should be stopped at the third leaf, but those showing fruit should not be stopped until the embryo fruit has been duly fertilised, and the corolla has closed over the impregnated organs; all the laterals should then be stopped at one joint above the fruit, the plant will then have the appearance shown in *fig. 19*, presuming it to have been trained with four shoots; and let the number be what it may, each principal shoot will resemble those in the figure.

From two to four fruit being set on each plant, their swelling will be materially aided by stopping at the first joint all growths from laterals not producing fruit, but those sub-laterals taking their rise from the axils of the leaves situated on the laterals producing fruit should not be stopped until a week or ten days afterwards, so that the food arrested by stopping the sub-laterals may not only be driven, but attracted past or into the fruit, the growing

*Fig. 19.**Fig. 20.*

point being situated above or near it. This being effected the fruit will swell rapidly, and by stopping the sub-laterals on the lateral on which the fruit is borne beyond the point at which this takes its origin, and the whole of the other sub-laterals on the plant being kept closely pinched in to one joint as fast as new growths are made, the whole strength of the plant will be concentrated on the fruit,

which will rapidly advance towards perfection. Continue to keep the sub-laterals closely stopped, giving those, however, on which the fruit is borne rather more freedom. Should the frequent stopping tend to overcrowd the main leaves from the principal and lateral shoots, the sub-laterals must be reduced in number by cutting them clean out, and close to the shoot or lateral from which they spring, so as to

expose the principal shoot and lateral leaves to light and air, in order that the food absorbed by the roots may be duly elaborated in the leaves, and these being kept healthy fine, full-flavoured fruit are the consequence.

It is quite possible that the embryo fruit produced on the laterals may not set or swell, or it may be that none is shown. In this case the laterals should be stopped at the third or fourth leaf, and this stopping will induce sub-laterals on which we may confidently look for fruit at the first, second, or third leaf. This being the case the sub-laterals are stopped at the third leaf; the plant will then appear as represented in *fig. 20*. The fruit being set and swelling freely, it is necessary to thin the sub-laterals, going over them twice—first, a week or ten days after the fruit begins to swell, removing two of those not producing fruit but not stopping any shoots whatever, only removing two of the sub-laterals on the laterals from the upper part, as shown by the cuts on the principal shoot, *d*, and this from every part of the plant, unless such be producing fruit as, *e*, on the lateral, *f*, and principal shoot, *h*, on the left, when the two sub-laterals below that on which the fruit is borne are stopped to one leaf each, thus *l*, and the shoots from the sub-lateral are not stopped but left to grow for some time. In case the fruit is borne on the nearest sub-lateral, *i*, on the lateral, *k*, on the principal stem, *l*, the sub-laterals and lateral are removed to the cross cut on the lateral, *k*; but those shoots springing from the bases of the sub-laterals are not stopped at that time, nor until a week afterwards. From a week to ten days after the useless sub-laterals are cut away, the growths taking their rise from the sub-laterals are stopped to two leaves, but if producing fruit to four, above the fruit, and if those left overcrowd the main leaves and stems, their number is reduced by degrees, so that the plant may not be gorged with sap, and gout result through an insufficiency of leaves to elaborate the food absorbed. After this the new growths are kept closely stopped, and thinned to admit light and air to the main leaves until the fruit is perfected, when the plants may be pulled up, and others planted in fresh soil if a second crop be desired; for Melon plants in houses after producing one crop are not worth keeping to afford a second.

In case the principal shoots do not set fruit on the lateral, or sub-lateral shoots, the principal shoots may be cut down to the two reserve shoots (which have been kept pinched in) at the base of the plant, and situated to the right and left respectively—viz., *m n*, in *fig. 20*, and shoots sufficient to cover the trellis may be obtained if the plant is vigorous enough and they must be trained in lieu of those cut away. Such shoots cannot fail to produce fruit immediately, but it will be small, though well flavoured. This method of training Melons is adapted for all low trellises, and is the same as that recommended in the case of training the Melon over the surface of beds without trellises.—G. ABBEY.

(To be continued.)

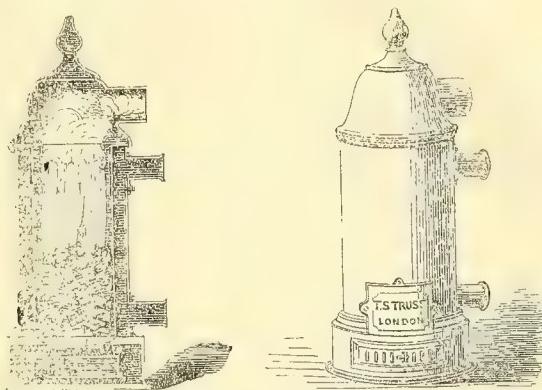

BOILERS WITHOUT BRICKWORK.

I NOTICE in the Number of your Journal published December 6th, that you say, in answer to "A CONSTANT SUBSCRIBER," on the subject of stove boilers—"We have reason to know that the boiler named soon burns through, and that all the so-called boilers without setting do the same. There is little if any difference in them, and they all do their work pretty well, subject to the drawback of the outer casing speedily burning through."

In reply I beg to state that by no means "all" the stove boilers burn through, as I can mention four or five manufacturers in London besides myself, who make stove boilers requiring no setting, and which do not burn through any faster than the ordinary saddle or conical boilers set in brickwork. These boilers are constructed with the fire in the interior of a cylindrical water space (see accompanying engraving), and no casing is used outside.

I may mention that I have erected this class of boiler in the Royal Horticultural Society's Gardens at Chiswick and South Kensington, and in many other places, especially in the neighbourhood of London, where I find they give great

satisfaction, as they are quickly and cheaply erected, and can be as easily removed if required for alterations.

I think you will see from the enclosed tracings that the boilers which I have described differ considerably from the one to which you allude in your remarks.—THOS. S. TRUSS.

[We quite assent to the above. Our observation applied to furnaces with boilers placed above them, not to furnaces the sides of which are formed by the boiler, for as long as this is kept filled with water no excessive burning can occur.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

No opportunity should be allowed to pass by, of getting the soil in a favourable state for the reception of the various crops which must soon be committed to it, and as the basis of success is allowed by all good practical gardeners to be a thorough system of drainage, no time should be lost in attending to this most material point. Whatever is done should be done well. Never allow a drain to be laid down that is likely to be deranged in its operation, as the good that may otherwise be derived from it would be nullified from the difficulty of ascertaining where the defects are. As this kind of work may be done any time when it is dry overhead, you will do well to look to it in time. *Broccoli*, these will be advanced by the recent mild weather, look over and select the most forward for protection in case of the return of frosty weather. Continue to remove all dead and decaying leaves. *Cabbage*, plants may still be planted or pricked out from seed-beds, and those planted in October should have a little soil drawn to them. *Garlic* and *Shallots* should be planted. *Peas*, the early ones which are breaking the soil may have a ridge of mould drawn over them, a covering of sawdust, old tan, or clean sand, is very good for the purpose, as it tends to keep the slugs in check. Set traps regularly for mice. Provide a successional supply of *Sea-kale* and *Asparagus*, in whatever way forcing is practised.

FRUIT GARDEN.

Orchard trees of large size are much neglected about many places as to pruning, the heads should be liberally thinned, cutting out all branches which cross the others, and dead pieces, and leaving the shoots sufficiently far apart that light and air may have free play among those left when the foliage is on. In removing large branches care should be used to make close clean cuts, and if the wood is coated with strong, thick paint, this will help to prevent its decaying before the wound is healed over. Also, take advantage of leisure time to thoroughly examine the fruit stores, and remove any that are found to be decaying. Of course, the frost must be excluded from here, but on no account use fire heat unless the temperature cannot otherwise be kept above freezing. Admit a little air on fine days, especially after keeping the room shut up for some time; but as the fruit will now give off but little moisture, very little air will suffice to keep the atmosphere dry, and no more than may be necessary to do this should be given. Any of the more choice varieties of Pears that do not ripen properly should be removed to a warm, dry room for a few days, which will be found to greatly improve them.

FLOWER GARDEN.

Laurustinus, variegated Hollies, or other such shrubs that have not grown kindly to be supplied with a top-dressing of rotten dung or leaf mould, to be lightly forked into the ground to give nourishment to the roots. If a similar want of luxuriance is perceptible in Rhododendrons, or other such evergreen American shrubs, they may be taken up and replanted with advantage, enriching the ground with a liberal supply of peat soil, or well decomposed leaf mould. Hoeing and raking the borders amongst shrubs will be sufficient to give them a clean and neat appearance, without the spade, to which we have a great objection when used to cut up the fibrous roots to debilitate the growth of shrubs that were planted to produce luxuriant and healthy growth as the most ornamental for pleasure-ground scenery.

GREENHOUSE AND CONSERVATORY.

As a moist stagnant air is most injurious to greenhouse plants at this dull season, we would advise a gentle fire to be applied during the day to expel damp; but heat and moisture should be reduced to the lowest degree possible compatible with the safety of the plants from frosts, and in accordance with the very small amount of light at this season. When high degrees of heat are kept up a large amount of water is necessarily applied, when elongation, or length without strength, takes place. Orange trees, or any other plants that have not been recently potted, to be fresh-surfaced by removing a little of the top soil and supplying its place with fresh. Pelargoniums to be kept rather cool and dry, giving whatever water they may require on the mornings of fine days, that the superfluous moisture may evaporate before evening. Herbaceous Calceolarias to be kept near the glass, shifted into larger pots if they require it, to be watered moderately through a fine rose, to be never allowed to get thoroughly dry, and when they require water it should be given before noon. The attacks of green fly to be prevented by fumigation with tobacco smoke; and when removing decayed leaves be careful not to pull or cut them off close to the stem, when the flower-shoots would be very likely to be injured by the operation. Camellias after the buds are set, and so far advanced as they are at this time of the year, require particular attention that they may not be excited too much by artificial means, nor must the temperature to be allowed to decrease for fear of the flower-buds falling off. Water also should be carefully given, neither saturating the soil to stagnation, nor allowing it to become too dry. When the Chrysanthemums begin to fade they may be removed to the north side of a wall, the pots plunged in old tan, leaves, or sawdust to protect them from the severity of the winter. Constant removals in the conservatory will at this period be necessary, for where a good reserve stock is kept, nothing should be suffered to remain which does not contribute to the gaiety of this structure. This change renders the whole more interesting; for in former days, before the special cultivation of winter flowers was understood, a most tiresome monotony prevailed: the Oranges, Myrtles, Oleanders, with huge American Aloes, appeared as if nailed to the spot. Take all possible means to avoid drip, and maintain the most perfect cleanliness and order.

PITS AND FRAMES.

Continue to give careful attention to half-hardy plants in these structures, taking advantage of every favourable opportunity to expose them freely to air. Anything of which there is but a small supply of plants to propagate from should be placed in growing-quarters at once, taking care to keep near the glass, and free from insects, mildew, &c. Softwooded plants in heat at this season are very subject to the attacks of insects.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

MUCH the same as last week. Gave plenty of air to Asparagus, encouraged Rhubarb and Sea-kale, and planted Potatoes in pots, to be grown in them, and others in small pots to be transplanted when we get a slight hotbed. Sowed also some dwarf Tom Thumb Peas in pots, and put some charred rubbish and burnt weeds by the sides of the young Cabbage plants, and also top-dressed with the same Cauli-

flowers under hand-lights, so that the surface soil may be as dry as possible. Will try and keep rain from them for three months. Gave manure water to Dwarf Kidney Beans. Thinned the Cucumber fruit in a small bed to enable it to keep on a little longer, and made a small hotbed for sowing the first crop under a frame. When the shortest day is passed everything will grow better and faster afterwards.

FRUIT GARDEN.

Proceeded with pruning and nailing as opportunity offered, as the spring will be sure to bring its own work with it. As soon as convenient we will daub our dwarf trees with a mixture of Gishurst, soot, lime, sulphur, clay, cowdung, &c., to clean the stems, and keep the tomits and bullfinches from the buds. Just now the tomtit does, we think, more good than harm, as he casts his sharp eye and little bill so knowingly into every hole and cranny in search of insects. In general he acts as a friend until the buds begin to swell, and then he will do his work in earnest, clearing a tree of its fruit-buds in a very short time. Last season, independently of netting, he made great havoc with Plums and Pears, and just began on Apples, when we managed to lose sight of him. He requires to be sharply looked after, for after and during hard weather you may not see him for a month or two; but most likely when the buds are soft and sweet he will bring not only himself but a whole cloud of relations, and they clear off everything as they go, pretty much like an invasion of locusts. Even now he may be easily poisoned by putting nux vomica or arsenic into pieces of mutton suet, but then, if we could only keep him moderate in his desires at bud-swelling time, we should feel sorry to interfere with the good deeds of the artful, little, pretty rogue at other times.

Gooseberry and Currants.—We generally merely thin a little, and defer full pruning until the bird-ravaging time is pretty well over. If we do not do it ourselves we hope that some of our readers will try these homely fruits trained to low trellises. It will be something strange if wasps do not touch them on these trellises. Amateurs who wish to have the fruit clean and nice, and to gather it themselves, without any danger of being troubled with lumbago, if they do not adopt the trellis plan, should have some standards at least 3 or 4 feet in height. A Currant tree is then a pretty sight in fruit, and so is a Gooseberry tree. The best way to secure them at first, is to insert a stoutish stick before planting, the stick rather higher than the top of the tree. Two cross wires fastened near the top of the stick, and a wire round at the circumference, would secure the tree well at first, and in a short time it would need no support.

Planting fruit trees may still be proceeded with. In many orchards the trees become covered with moss and lichens, and prematurely decay, from too deep planting. Nature herself will give an admirable lesson here. Every tree if self-sown, and with plenty of room to grow, will, less or more, be found to stand on a little mound, and the roots will be found extending near the surface of the ground, as well as at greater depths. With trees hardy enough for the climate, and which we wish merely to grow for timber, it matters little how deep the roots grow. In fine, mellow, loamy soil, there is no great necessity for planting even a fruit tree on a mound, though every reason for not planting it deep. All tender trees, and all fruit trees should be shallow-planted. In the case of tender trees, the less the growth the more fully will the growth be ripened, and, therefore, the better will it stand rough vicissitudes. This holds not only true in the case of fruit trees, but as we also grow them for fruit, and not wood, we should bear in mind, that the nearer the roots are to the air, and sun heat and light, the more will the fruitful parts preponderate over the mere growth developments.

Bush and Pyramidal Trees in gardens, therefore, will in general thrive none the worse for being elevated on little mounds. In thin sandy soil a greater depth is thus secured, and the roots run beyond the mound at a shorter distance beneath the surface. In very rich soils, with or without a heap of stones or clinkers beneath, the mound will help to check over-vigorous growth. In deep, cold, clay soils—at least with clay bottoms—the tree has a better chance to send its roots in the best soil, without being enticed to go deep, and be gorged with unhealthy matter fruitful of canker

and other evils. If the roots, by concreting or other means, can be prevented going down at all into such cold damp soils, the better will the trees flourish. The mounds also give a better chance for root-pruning if that should be necessary, and richness and moisture near the surface may easily be secured by top-dressing and mulching. In soil at all moderately rich, we would mix no manure whatever with it at planting time, but we would top-dress with leaf mould or rotten dung every year as long as the plant required it. Even if it became too strong and vigorous we would prefer root-pruning or replanting rather than discontinuing this surface-dressing, as the masses of mop or wig-like roots near home are more serviceable for producing and feeding plenty of fruit than lots of long naked roots going ever so deep. In planting on mounds, supposing the mound to be 4 or 5 feet in diameter, the centre may well be from 12 to 15 or more inches higher than the surrounding level.

Strawberries.—Nearly finished cleaning beds in the open air; removing all runners, thinning where too thick, but leaving the old leaves on the plants to act as some protection; then hoed or forked an inch or two in depth between the rows, and placed on the space a layer of rough, rotten, hotbed manure. Watered plants in pots under protection in orchard-house, as when now allowed to become too dry the flower-bud is apt to perish. This is more necessary in our case, as, owing to the drought of summer and little water to give them, our plants are in smaller pots than usual. Moved a lot of plants from a frame, where some were showing the buds, into a small pit where we have some Vines, and which we will start slowly. We will keep the pit rather close a few days, that the plants may sustain no check in being removed from the damp frame at this season, they having had a mild bottom heat from tree leaves. Nothing is better than such a frame for starting such plants; but anything like a check afterwards, either from a dry heat or a lower temperature, does harm to the Strawberry plants. We have placed them thick in the brick pit, as by the time they want more room we will be better prepared for thinning them. They are placed on narrow boards, with just a sprinkling of leaf mould on them, and that we like better than pans or flats at this season. We put a little hay and litter over the pots of trees in orchard-house, in case we should have a sudden frost; the wind from the north-east is cold enough for anything. Will prune and wash here at the first opportunity.

Forcing Vines, Peaches, and Figs may now be commenced, to have ripe fruit in June, beginning very slowly at first with a moist atmosphere, and a temperature ranging from 45° to 50°, raising it a few degrees each week until you approach 60°, above which the temperature should not rise by fire heat until the buds of Vines are all broken, the flower-buds of Peaches set, and the young Figs swelling. Where a little bottom heat can be given to early Vines it will be an advantage. Where the roots are out of doors the ground should be well, or, rather, early protected, to keep in the summer's heat. It will always be advisable to have a little heat in the border before raising the temperature much above that which is necessary to keep out frost in-doors. The mere excluding of frost by keeping plants under the shelter of forcing-houses does them no harm. But if such trees as Vines and Peaches have a little frost, but not enough to injure them, we think it helps to keep them more free from insects. On the other hand, it is right to state that we have seen Peach trees out of doors, exposed to a frost that was quite as much as they could stand uninjured, and yet be eaten up with insects early next season; whilst a few feet from them trees protected by glass, and frost just excluded, had not an insect on them the following season. All general rules have their exceptions. A few Figs out of doors we will give a little protection to before the frost becomes severe; but after having them in-doors in plenty, they have become of less use to us.

ORNAMENTAL DEPARTMENT.

Our chief work has been collecting leaves and thoroughly cleaning, and sweeping and rolling the pleasure grounds. The leaves have come down so irregularly that this has been a long, trying job this season, and nothing in a fine day, even to say nothing of a dull, foggy one, so much tends to conjure up morbid and melancholy feelings, as lots of leaves on walks and lawns, undergoing the first processes

of skeletonising. Our walks are so smooth that we are a little in doubt as to rolling them after this last sweeping. If we do so our chief object will be to make them firmer, so as to throw off the rains. A very smooth walk is not such a luxury in winter as it is in summer; and in fine weather in summer, walks, except in show places, however nice, are scarcely ever used. Who would tramp on gravel when he could use the carpet lawn? Where much walking is necessary in winter, the lawn will generally be too damp, and except for the thin gosshes of ladies, a roughish walk that will leave nothing on the soles of the boots, will be quite as pleasant as a smooth walk, if it leaves marks of the foot-steps. It is not easy to obtain both advantages. For smoothness we use a slight sprinkling of fine siftings every year. For roughness in winter all the large stones, and all the fine sandy siftings should alike be excluded. But for the first expense, walks in small places would be cheapest in the end, if formed of stone or pavement, or even of thick asphalt, but then they, too, would be too smooth, and sometimes dangerous in winter.

Worm Heaps on Lawns.—These are great eyesores, when a bright level expanse of green is the great object aimed at. In small plots the best and most effectual remedy is to roll the lawn, and then in a day or two when the holes are open to water it over well with clear lime water that is made by placing a good spadeful—say half a peck or more of quick-lime in a hogshead of water, stirring it well and using it when clear. This will also banish them from the sides of walks. Salt would be more effectual for the latter purpose, but then it would also soften the walk. In large lawns it is almost impossible to use lime water all over, but a few places may be done near the mansion. The remedy for large lawns, however, must chiefly be the roller. A wooden one such as a boy can draw is best, and as the worm heaps encrust it, the earth must be scraped from it. A large space of lawn may thus be gone over quickly. A handy wooden roller may be 10 or 12 inches in diameter, and $3\frac{1}{2}$ to 4 feet in length, furnished with a light wooden handle to pull by. Such a roller is as useful for a lawn in winter, as a daisy-knife is in summer. Sweeping worm heaps, unless in very dry weather, is an unsatisfactory process. The roller leaves a better appearance behind it with a tithe of the labour. Besides, the worm dislikes the sound of the roller, and departs to his deeper fastnesses for protection.

Besides attending to plants in general, we have put Roses, Dielytras, Deutzias, and other shrubs in frames and beds where they can have a mild bottom heat, preparatory to more forcing. Planting of all kinds may be proceeded with, and if tender Roses have not been taken up they should be protected with fern, spruce branches, &c. Many things, as Fuchsias, should have their roots protected with moss, ashes, or sawdust; and Hollyhocks will be the better of having mounds of such and charred rubbish placed over the roots; Dahlias we keep in dry earth in a shed, like Potatoes, and have rarely lost a root.—R. F.

COVENT GARDEN MARKET.—DECEMBER 17.

The market continues well supplied, out-door fruit and vegetables being plentiful, while of Grapes and Pines there is sufficient for the demand. Quinces are becoming scarce, and will soon be over. In forced vegetables good Sea- kale and Kidney Beans may now be had, but Rhubarb has not as yet made its appearance. In Potatoes prices are fully maintained. Christmas trees are now brought in large quantities, and the greengrocers are laying in their stock of Holly and Mistletoe. The showy scarlet-bracted Poinsettia pulcherrima is also plentiful. Other flowers chiefly consist of Heaths, Camellias, Azaleas, Chrysanthemums, Chinese Primroses, Mignonette, with a sprinkling of Perpetual Roses.

TO CORRESPONDENTS.

SEA-KALE-FORCING (*Dorset*).—The plants suitable for placing in frames are those with crowns fully an inch in diameter, and such are usually three or four years old from the seed. Plants once taken up and forced are not worth keeping for the same purpose again, though they will gain strength in a year or so, and may then be used, but they are not equal to younger plants, and nothing is gained by keeping them.

SIZE OF MELON-PIT (*A. T. S.*).—The height of the Melon-pit (fig. 12 in our No. 184) is 7 feet from the floor to the apex, and how you make it only 5 feet we are at a loss to know. You may readily ascertain the dimensions of the pit by measuring the engraving, and reading it off on the scale.

PLANTS FOR A DRY BORDER (*A Lady Subscriber*).—There are no plants that will flourish in a Clematis-shaded dry south border except the different kinds of Ivies, and these we think will be the most suitable for your purpose. Periwinkles might also grow, but there are no flowering plants that will flourish in such a situation for any length of time. Lobelia likes a wet soil, Ceratium might succeed, and it, with Geraniums, would do the best in summer. Stachys lanata will grow well in many places where few other bedding plants will succeed. Thompson's "Gardeners' Assistant" is the best of the works named by you.

ARRANGING FRUIT TREES (*M. L. T.*).—If we understand you aright you have a hedge 84 feet long on the south, and a wall of the same length on the north, and on this you may have Peaches, Nectarines, Apricots, and Fig trees, or one Grosse Mignonne Peach 8 feet from one end, then an Erluge Nectarine 25 feet from it, then a Brown Turkey Fig 13 feet distant, a Royal George Peach 15 feet from the Fig, and a Moorpark Apricot 15 feet more; and there will then be room for another Apricot 12 feet from the last. You may plant the east and west borders with Pears at 15 or 20 feet apart—say the west with Pears, reserving the east for Plums, Cherries, and Black Currants. The Plums should be planted the same distance apart as the Pears, and the Cherries at 12 feet distance, whilst the Currants may be planted a yard apart, especially if the board fence is a high one. We do not think Medlars would please you. We do not know whether we have read your letter aright or not, nor can we make out what is meant by the fence 84 feet long by 18 feet wide. If the wall is covered with trees, and you only wish to plant trees against the boards, then you will not plant the Peaches and Figs, nor any of the fruits named for the south wall, for they will do little good in such a situation, even in Devonshire. The other trees named by you will do well on the east and west aspects. Not knowing the length of the east and west borders we are not able to tell how many trees it would take to plant them.

TAGETES SIGNATA PUMILA AS A BEDDING PLANT — PASSION-FLOWER PRUNING—BIGNONIA RADICANS AND CAPREOLATA (*E. G. H.*).—There is more than one yellow bedding plant named Tagetes, of which the yellow varieties of French Marigolds are no mean objects; but Tagetes tenuifolia has yellow flowers, much smaller, but in greater profusion than those of the French Marigolds. It is, however, a tall plant from 2 to 2½ feet high, and is only suited for large groups. Tagetes signata is a fine bedder, but, like the last, is somewhat tall; but its variety *T. signata pumila* is only a foot or so high, and makes a fine golden mass. It is a half-hardy annual, requiring to be sown in the first week in March in a compost of light loam and leaf mould, and placed in a hotbed. When up guard against drawing the plants up weak by admitting air daily, and otherwise endeavouring to insure sturdy growths. When large enough to handle pot off in threes round the sides of small pots, again place in the frame, and keep rather close for a few days, then gradually harden off, and plant out in the last week in May or first of June. They are a little more tender than French Marigolds. You will not gain anything by cutting the Passion-Flower down, and you may lose the plant if you cut to the old wood without any eyes upon it. Cut it in to within three or four eyes of the main stem, or shorten the young shoots to that length in January, which will answer your purpose much better than cutting it down to the roots. If it has a long naked stem it may be cut down to within a foot or so of the soil, and if there be young wood there by all means leave a few eyes on it, for it will shoot again with much greater certainty from the young than from old wood, which may or may not have some dormant eyes. It ought to flower before another Christmas. Bignonia radicans is distinct from Bignonia capreolata; the latter is a more tender plant, requiring the protection of a greenhouse, whilst the former is all but, if not quite, hardy. They are, however, somewhat similar, and though distinct enough for large collections, are, perhaps, not so for small gardens. You can grow it well trained to the roof of a greenhouse at a few inches from the glass, either planted out in a border or potted in a good-sized pot, using a compost of turfy loam and leaf mould, with a free admixture of sharp sand. It requires abundance of light and air, and plenty of room.

VARIOUS (*T. H.*).—The half-half binding of our annual volume would be about 5s. The insect is a scale (*Coccus*), and is destroyed by painting over it with soft soap, &c., as often detailed in these pages. The price of Hogg's "Gardeners' Year Book" is one shilling.

TAKING UP GLADIOLI BULBS (*A. S. A.*).—The bulbs should be taken up when the foliage turns yellow, drying them, keeping them in a cool dry place, and replanting in spring. Payne's cottage hive, sold by Messrs. Neighbour & Son, Regent Street, London, will suit you.

VINES MILDEWED (*D. M. S.*).—The Vines may be mildewed from being grown in a close moist house, and their roots being in a rich undrained border. They may not be mildewed for these reasons, nor can any one assign a cause for every attack of disease, though there may be some peculiar state of the juices of the plant which makes it liable to the attacks of insects and parasites. The cure rests in dusting the parts affected with flowers of sulphur whenever the disease presents itself, and this, with attention to the minutiae of Vine-growing, which may be learned from the "Vine Manual," which you can have free by post from our office for thirty-two stamps, will prevent the Vines suffering from mildew. The oil cloth placed over the border in winter will be of great benefit to the roots in keeping them dry, but this will not prevent attacks of mildew. Dust the leaves with flowers of sulphur whenever the mildew shows itself, and this will keep it down, and if persisted in will effectually rid you of it; but do not wet the sulphur and rub the leaves with it, for by so doing you can never reach the parts affected, and at the same time you will injure the leaves. The mildew may or may not re-appear another season.

STAINING OAK-PALING (*A Subscriber*).—The light colour may be permanently removed by brushing it over thoroughly with linseed oil.

NORTH OF SCOTLAND (*A Subscriber, Aberdeen*).—The best mode of introducing common Primroses would be to procure some plants in very early spring, and place them in sheltered shady places near you. Our correspondent adds—"Contributions such as that from your friend from Fort Augustus in the issue of November 29th, greatly enhance the value of your Journal in this part of the world; but he omits to tell your readers two things of importance—first, how he grows his Roses, whether as dwarfs, half-standard, or standards; and second, what description of stock he has found so successful. He tells us in two rather lengthy paragraphs it is not the Dog Rose, but he evidently, by accident, omits to say what it is. It would be very interesting also to Rose growers in this quarter, where the cultivation of the Rose as standards has been but partially successful, to know your correspondent's general mode of treatment throughout the year, especially his manner of preserving them during winter."

VINE LEAVES (*An Old Subscriber*).—There are no scale insects upon them, but symptoms of gangrene, intimating, we think, that the roots are not sufficiently active to supply sap for the growth of the leaves, &c. If the roots are outside the house we should cover the border with fermenting dung 2 feet thick, and place over that a tarpaulin, or something else that will exclude excessive rain, or other chilling circumstances.

LAVING OUT AND MEASURING GROUNDS (*T. M.*).—There is no book specially devoted to these subjects. There is much about them in the first volume of McIntosh's "Book of the Garden."

MONOCLEUM ENSIFERUM LEAVES SHRIVELLING (*Item*).—It is probably losing its leaves, and the shoots dying back through being grown in too cool a house. It requires the heat of a rather warm greenhouse, though it will do fairly in a dry greenhouse with little water, providing the wood be well ripened in summer.

HEATING FROM A KITCHEN BOILER (*W. E. H.*).—We should be more certain did we know the exact height of the kitchen boiler and the floor of the conservatory. The lower the boiler beneath the pipes in the conservatory the better—that is, at least for several feet, provided the top of the boiler is closed. As your boiler is open, you can have no pipes in the conservatory higher than the general level at which the water stands in the boiler, in no case quite so high as the top of the boiler. You may use two or three-inch pipes, one within 3 inches or more of the top, and one near the bottom of the boiler, as the connection between the boiler and those in the conservatory. These pipes when in the kitchen may be enclosed in a wood case. These may be placed on the same level in the kitchen, except where they enter the boiler. The pipes must not sink below nor rise above the level of the water in the boiler. If you wanted a heat of from 45° to 50° in cold weather you would need three four-inch pipes in the front of the conservatory. These may all be on the same level, with a shelf over them. Thus the flow-pipe from the boiler could join a double pipe, and these could join at the farther end to receive the one return-pipe. All things considered, we believe the kitchen boiler to be your best mode; but if the boiler is much on the same level as the pipes in the conservatory these pipes must neither rise nor fall.

VINES IN POTS (*D. D.*).—If you wish to trust your Vines in 10-inch pots we decidedly advise you to let them remain in the same pots, but use rich top-dressing and manure-waterings, and you may even place some good soil below the bottom of the pot in the bed, and let the roots run in it if they choose. A little bottom heat will be serviceable. Do not shift now by any means if you wish good fruit and plenty of it.

SEAWEED AS MANURE FOR CARNATIONS (*—*).—It is a good manure for them, but should be thrown together and allowed to decompose, and then be mixed with three or four parts its bulk of light sandy loam. If not experienced we would not advise you to use it largely.

EARLY GRAPES (*J. B. Charlesworth*).—To obtain early Grapes in the way you alude to requires considerable experience and care. Allowing the late Grapes to hang till March will require much less care and expense.

VARIOUS (*M. H.*).—If the Lilles and the Dielytra are very dry at the roots they should be watered before plunging them in the forcing-bed. It fair for moisture—that is, neither wet nor dry, they will absorb moisture from the bed of leaves, and in that case we would not water until the tops began to grow. We would not repot any such plants, but top-dress with rich material. Your proposed house on the north side of the wall will do well for foliate plants and Ferns. You do not say the height, but for a moderate heat you would need at least 120 feet of four-inch pipe to keep stove fine-foliated plants healthy. You could keep Camellias and Azaleas admirably in such a house in winter, or at any time, except when making growth and setting their buds; but then you could not keep Ferns, &c., that required much heat at the same time, as the extra heat would be too much for the Azaleas and Camellias.

BOOK (*R. H. A.*).—The "Fruit-Gardening for the Many" will suit you. It can be had free by post from our office for five penny postage stamps.

ADDRESS (*Stella*).—Mr. West, when we last heard of him, was residing at Bournemouth, Hants.

CHrysanthemums not Flowering (A Young Amateur).—We have little doubt that stopping them so late as the middle of July was the cause, and certainly so if you live in a cold district.

VINE-GRAFTING (A Subscriber).—Take the scions from the Barbarossa at the time of winter pruning, and select such shoots as have the wood well ripened, the joints short or close together, and moderately strong, or about the thickness of the middle finger, not thicker, nor of smaller size than that. Other sizes and descriptions of wood will of course do, but for a strong stock we like the scion strong; but if the stock be young and small the scion should be of equal size, or rather under than above the thickness of the stock. Keep the scions with their lowest ends stuck in moist soil in a cool house. When the eyes of the stock begin to swell, cut it down to within a few inches of the place desired for the insertion of the graft or scion. Choosing a smooth part of the stock, about 6 inches below the point to which the stock headed down, with a sharp knife take a slip of wood about an inch and a half long from the side of the stock (b), making a clean cut. Take the scion (a), and cut it from behind an eye downwards, so that the cut made may exactly correspond with that on the stock. The cut should be made at the lowest end of scion. Next make a sloping-downwards cut in the stock, and about three-quarters of an inch in length, and half an inch deep, commencing half an inch from the upper part of the first cut. A sloping cut must now be made in the scion from the bottom upwards, exactly corresponding to the cleft made in the stock, so that when the scion and stock are joined together they will fit into each other. Insert the scion in the stock after heading the scion down to three eyes, taking care that the two fit bark to bark; or, if the stock be thick, on one side at least. On this the success of the operation depends; therefore particular care must be taken to insure the bark of scion and stock being in contact. The scion being adjusted, bind it closely to the stock, but not too tightly, and be very careful not to displace the scion. Matting or Cuba bast is the best for tying. The point of union may then be covered with clay, but if the operation is neatly performed a little sphagnum wrapped round will answer quite as well. If the scion take, the matting may be loosened in about six weeks, and removed altogether a fortnight afterwards; and when the graft grows vigorously that part of the stock above the graft should be cut away, which can be done more safely at the summer than at the winter pruning. One shoot only will be required to train up the rafter, so that the strongest being selected after the scion fairly shoots the other two may be rubbed off. If it be late before the stock is ready for grafting the scion may be stuck in a Potato. The time of grafting will depend on the time of year when the stock commences growth. So far as we know the stock has no influence on the flavour of the fruit, and a Barbarossa on a Black Hamburg will have the same flavour as if on its own roots, just the same as Peaches on the Plum have no trace of the flavour of Plums.

SHIFTING HEATERS AND AZALEAS (A Constant Reader, Dunbar).—When the plants have done blooming and are beginning to grow, is a good season to shift these. March is a good time to shift Heaths; April, May, and June for Azaleas blooming in the months preceding those named. Mildew on Heaths is chiefly caused through a damp close atmosphere, for which there is no remedy but more efficient ventilation.

PYRACANTHA PRUNING—CHRYSANthemum CUTTINGS—FERNS POTTING—CAMELLIA-BUDS NOT EXPANDING (Rose-bud).—The Pyracantha should be pruned in spring, cutting out or thinning the shoots, so that they may not overgrow each other nor grow too far from the wall. By training-in some young shoots from the bottom between the old, you will probably obtain berries at the bottom as well as the upper part of the shrub. For the cuttings of Chrysanthemums singly in small pots, and place in a gentle heat where they will soon root. When rooted harden off and winter in a cold frame, protecting from severe frost by a covering of mats. Pot in March into 24's, stopping the plants to five leaves; pot again in May into nine-inch pots, and if large plants are desired, transfer them to 12 or 13-inch pots early in July. A compost of turfy loam and leaf mould, two-thirds of the former to one of the latter, will grow these plants well, adding a little sharp sand if the soil seems deficient of it. The plants may be stopped in April to make them bushy, again in the latter part of May, and for the last time by the middle of July. The most suitable time to pot Maiden-hair Ferns and all Ferns, is before or when they begin to grow, and that time is March or the beginning of April. The Camellia does not expand through an imperfect root-action, and there is no remedy but to plunge in a mild bottom heat, with a top heat of 50° by night.

FRUIT TREES ON AN EAST WALL (Under the Shade).—We have no doubt that Pears would do the best on clay soil in a damp climate. You do not state the height of the wall. If it be low (10 feet), one tree will be sufficient; but if more than that height two will be required. By the Duchesse Pear of Jersey, we presume you mean Duchesse d'Angoulême, a noble-looking Pear, but with us not first-rate from a wall, though rich and melting from espaliers. We think Marie Louise, in season in October and November, and Glou Moreau, in season in December and January, will suit you. It will be a good plan to dig a rather large hole and put in some good loam or rich compost so as to give them a good start. There is no better stimulant for Vines in such a position as yours than applications of weak liquid manure once or twice a-week. The Arums died down through the dryness of the situation we should think.

GRAFTING ROSES ON THE MANETTI STOCK (A Subscriber and Lover of Roses).—Prior to grafting your stocks should have been established a year in pots. You may, however, do as you say, pot them now or not until you graft them in February, and then plunge them in a hotbed. You may graft before potting, and you will need no clay, only graft low enough that the point of union can be covered firmly with soil, leaving three or four buds of the graft above the surface. Whip-grafting is the best mode, and that will render it necessary to head down the stock at the time of grafting. Owing to the stocks not being established a year in pots, the plants will only make moderate growths the first season. Except some few of the Hybrid Perpetuals, and these, the dwarf and moderate growers, all do well on the Manetti stock. To give names would only be repeating them from a catalogue.

DISEASED PEAR TREES (*Pyrus*).—The cracked fruit and blotched leaves indicate that the roots do not supply sufficient sap. Remove the soil from above the roots within a circuit of 4 or 5 feet round each tree, and replace it with fresh soil mixed with well-decomposed stable manure. Mulch over the roots in summer. Your Mosses are—1, *Bryum ligulatum*; 2, *Hypnum lorenzii*.

VARIOUS (C. E.).—We have carefully read over your two letters. We regret we cannot give you a correct section of the Muscat-house at Envile, as at this distance of time we might make a mistake in some minute matters. We will, however, privately put you in a way for securing what you want. Meanwhile the description given at page 354 of an early viney would supply much of what you want for an early Muscat-house. In a house 14 feet wide we would have three four-inch pipes for bottom heat, either covered with rubble or, better still, in a chamber with slate over it, and 6 or 8 inches of rubble over the slate, and then from 20 to 24 inches of open turf soil. The rubble with openings would secure thorough drainage. One reason why the Vines planted in old Pine-beds in large houses, after all the tan was removed, and suitable soil was put in its place, were more affected with mildew than in the case of Vines planted out of doors, we believe to be owing to the want of drainage, and perhaps the want of heat at the roots. If two four-inch pipes had been placed in the bottom of these old Pine-beds, rough rubble or stout slate placed over them, 6 or 8 inches of rubble above that, with a few little openings in the front wall of the pit to let out extra moisture, and then plenty of piping for atmospheric heating, so as to give plenty of air, we believe that mildew could scarcely be present, or continue long if it did make its appearance. In such circumstances we have seen fine Grapes produced free from all disease, as the roots and tops were completely under control. We have seldom seen a more elegant house for Pines than the section shown at page 355, and commanding more conveniences. Were that house to be used for an early viney or Muscat-house we would prefer the house to be 1 foot or 15 inches higher at the ridge. We would require no pits, but have a latticed path underneath the ridge, four pipes, as now, in a shallow chamber, rubble above, and then the soil, four pipes in front above the level of the shelf shown, and two at back close to the wall. The Vines to be planted behind the front pipes and in front of the back pipes—say a foot distant in either case. But we feel convinced that in saying this your judgment is quite as much to be relied on as ours. Your present long range of houses facing south-east would be much improved by a hipped roof. So far as we recollect the sash-bars and glazing were old. The heavy rafters and sash-bars gave a great amount of shade. The capping of the rafters might be reduced with advantage, and when fresh sashes were wanted, the glazing with large instead of small squares would be a great advantage. It is impossible in your climate to have too much sunlight if you have ventilating power to counteract it when necessary. We should approve of your proposed arrangements for such a new range, and a large tubular boiler, or even a saddle-back would answer. If we have any preference for the former it is because it is easier fed with fuel from the top. If you use the whole square for forcing purposes we would prefer having two boilers to use combined or separately—the one as a reserve. It is too much risk to have such a square of forcing-houses depending on one boiler. After seeing much, and experiencing much, and incidentally speaking well of some boilers, our real opinion is that there is but little difference between them when well set and well wrought. As to iron houses, they have the advantage of lightness and durability, and if well painted and carefully glazed—that is, neither tight nor loose, they will answer the purpose quite as well as wood if the sashes are fixed. Houses will ever be more economically managed if the roofs are fixtures, and the ventilators placed back and front, independently of the roofs. For general purposes it is a good plan to have the rafters and main supports of iron, and the sashes of wood. Great lightness will thus be secured, and the houses will require much less firing than if all the bars were also of iron. Paint as you will, iron roofs will cost more for fuel, and require more ventilating power in summer. One great drawback in iron roofs is that if neglected as to painting the drip from them is ruinous to all vegetation beneath them. Wooden houses are now built very light, but where much was done and fine effect an object, before building it would be worth your while to look at the houses of Mr. Bewley, Blackrock, near Dublin, where some arrangements will be found worthy of adoption, or affording hints for our practice. We rejoice to know that the grounds at your ancient place are likely to be laid out so beautifully. You will find some good hints in the "Vine Manual" published at our office.

INSTRUCTION (A Young Under-Gardener).—We should have answered you sooner but your letter was overlooked. We should recommend you to select Trentham.

BRITISH FERNS (W. W. Denslow).—Mr. F. Y. Brocas, of 25, Hart Street, Bloomsbury Square, can supply collections of Ferns as required. Mr. Brocas has for some time been preparing sets of Ferns and other plants for Christmas and New Year's presents.

NAMES OF FRUITS (D. O. R.).—They must be local varieties, for we do not recognise one of them. They probably came from the cider district.

NAMES OF MOSSES (C. P.).—1, *Hypnum alopecurum*; 2, *Bryum ligulatum*; 3, *Marchantia*; 4, *Dicranum scoparium* (approaching *Dicranum majus*); 5, *Dicranum scoparium* or *Dicranum Dilatatum*; 6, *Polystichum undulatum*; 7, *Hypnum splendens*; 8, *Hypnum dendroides*.

NAMES OF PLANTS (Trevelyan).—1, *Polypodium vulgare*, and 2, its var. *cambicum*; 3, *Blechnum spicant*. (C. D., Westmeath).—1, *Lastrea dilatata*; 2, *Asplenium adiantum-nigrum*. (G. L.).—*Calanthe vestita*. (A Welshman).—1, *Maxillaria*, perhaps *aurea-fulva*; the specimen is insufficient; 2, *Next week*; 3, *Lomaria borealis*; 4, The young barren frond of some *Lomaria*, perhaps *lanceolata*; 5, *Pteris cretica*; 6, *Asplenium bulbiferum*. (M. C.).—1, *Cyrtomium falcatum*; 2, *Adiantum concinnum*; 3, *A. reineferum*; 4, *Selaginella robusta*; 5, *Selaginella* sp. (bad specimen); 6, *Aspidium hispidulum*; 7, *Selaginella pubescens*. (A Welshman).—2, *Selaginella Galeottii*. (A Lady subscriber).—1, *Lastrea dilatata*; 2, *Selaginella pubescens*; 3, *Asplenium marinum*; 4, unnameable from such a bad specimen.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BRAHMA POOTRAS.

In discussing the purity of any breed, the defence must depend somewhat on the nature of the attack. The assail-

ants of the poor Brahmans are of two kinds. On the one hand they are hybrids; on the other, they may be pure, but only a variety of Cochin. Much has been written on both these points. Were the first position tenable, should we not, long ere this, have arrived at instances of the Chittagong, &c., &c.? and, when I say *we*, I do not mean I—by myself, I—in my alphabetical capacity—but all those Brahma breeders who have no other object in view than truth; for, in starting, it may be at once laid down as certain that the question of purity, even if settled adversely to the Brahmans, would not shrink their admirers, whose name is legion. We have learnt to value them for their many useful properties, which, as was lately noticed by one of your correspondents, other breeds do not possess; and I suspect we shall stick to them. Certainly, if we did so during the many years of suspicion and coolness, more certainly now, when they may be called the popular fowl, and when schedule-framers are beginning to find out that they enter well.

Looking to either method of attack, the question of history and origin is a matter of importance; but is it an essential? Is it a *sine qua non* of a pure breed? If so, our "pures" will be sadly curtailed. Let us turn to the "Poultry-Book"—that beautiful work which one of "our Editors" assisted in giving to us lovers of fowls—what do we find there?

Dorking: "We have sought for information as to the time when Dorking and its fowls first became noticed, but our inquiry has been fruitless." The history and origin of the Dorking, though styled *par excellence* in that book the "English fowl," is involved in uncertainty.

Spanish: "Best Spanish have been obtained from Holland." There is a very probable reason assigned; still it is very strange that the best should have migrated to Holland.

Hamburgs: Origin uncertain.

Game: No account given, simply that they are essentially English.

Cochin: These seem undoubtedly to have come from Shanghai; but, despite the efforts made to call them by their right name, Cochin has stuck to them.

Polands: "Which of these is to be considered the Polish birthplace we are not specially informed, nor does it appear probable that any inquiries, however carefully conducted, are now likely to settle the question." "With Poland, certainly, we have nothing to connect these birds."

Now, in these two latter breeds we have a country giving its name to certain breeds, yet having nothing to do with them. May not this be the case with Brahmans? I know nothing of Dr. Bennett, but it is possible that, having got at the source of the Brahma, he may have given it the name of Brahma Pootra for the very purpose of misleading others, whilst, perhaps, they may be found somewhere on the American continent. Nay! he may have gone further—he may have stated the descent as a cross for the same purpose of misleading; and, as Barnum had something to do with them, it is more than probable that all we know from American sources is "Hum!" To all this we can only say, If history and origin are essential, what must be said of the many established and pure breeds that have not got any?

Hybrids, it is allowed, return to one or other particular type; and as the Brahmans have been with us some fifteen years—I have myself kept them some eleven or twelve—it is time they reverted, if they ever intend doing so. Still they show no signs this way; but, on the contrary, they have become more settled, and points of feather are actually being insisted on. This is a hybrid, forsooth!

I turn again to the "Poultry-Book" ("Brahma Pootra," page 177), and there I read, "There are birds of the Malay and Shanghai families by whose union such colours would probably appear." To this is appended a foot-note, that in 1853, at Farningham Show a pen of fowls was shown very similar to the Brahmans, and stated to be a cross between Malay and Speckled Dorking. Yes, but were these feathered? I know not. The "Poultry-Book" then continues—"If the test of like producing like for several generations should be successfully afforded by Brahma Pootras, other grounds must be sought for by those who would consign this alleged variety to the comparative ignominy of a hybrid origin." I would draw especial attention to these words. It appears to me that the Brahmans have bred true to feather—that

like has produced like: therefore Brahmans, using the argument of "our Editors," are not of hybrid origin.

If this part of the argument is satisfactorily disposed of, let us see whether they are only a variety of Cochin. Were I asked the question, I should reply as distinctly as I could, Certainly not. To decide this very knotty point, let us see what are the characteristics of a pure breed. According to notes from "our Editors" I gather that many distinctions which our sharp-sighted predilections discover amount to nothing, and only prove a variety. I set these aside, therefore, not that I consider them of any importance, and I take these words of "our Editors" as my guide—"If a bird is like another in its form and plumage, they are of the same species." While I write these words I fancy I hear my old bird crowing—he happens to be miles and miles away—as though he would say, "Do not spare them. Hit them hard, though they have got plenty of friends;" and thus encouraged I turn again to the "Poultry-Book." There I find the back of Cochin described as "flat." This description is followed by that of Mr. Sturgeon, no mean authority, by-the-by. He says, "*drooping forward, with the hinder part consequently raised.*" These italics are my own. When I bred Cochins, and loved them dearly for many years, I liked my birds to rise from shoulders to tail. I believe the best birds are so now. I put it plainly to all my brother Brahma fanciers, Is this the form that we desire in our pets? Certainly not. On the contrary, we desire a drop from the shoulders to the tail; the very reverse, in fact, and in the "Poultry-Book" I also find this given as characteristic of the Brahma.

Again I find a decided difference of form in the brow as compared with the Cochin. It may be argued, these differences come from the Malay origin, but by the previous extracts from the "Poultry-Book" I consider the hybrid question disposed of.

There is a further difference in form in the tail; not only is it longer and more upright than that of the Cochin, but the sickle feathers separate, curving outwards like that of the Black Cock. This I have not seen in Cochins. In the Brahma hen I have frequently seen what I consider the equivalent of this—one feather on each side separate from the rest.

I think, too, there is no question amongst those who have eaten both that there is a greater depth of breast in the Brahma.

Are these "differences of form" sufficient? If not, I have failed. To those who do not think them sufficient I tender yet a few observations. Are the differences of form between a reddish-faced Spanish and a whitish-faced Black Hamburg as marked? The combs are immaterial, and it will be observed that I have laid no stress upon the form of the Brahma comb, now generally seen. Again: are not these differences greater than between Game and Game Bantams than those that exist between Black Hamburg and Black Bantams?

When to the differences of form, considered essential by "our Editors," we, who have watched them closely, detect differences of character in the Brahmans to the other variety; but to all it is but fair to say, if they are not hybrids they are equally distinct from Cochins. The characteristics have been noticed at various times lately in your pages: one that I have not seen noticed is the greater precocity of the cockerel—he crows earlier, &c. All these help to prove the position. But I have chosen to stake my hobby on the difference of form, and as I have said before, prove them the veriest mongrel, I shall not think one iota the worse of them. Were I compelled to resign all save one, then Brahmans for me.

In conclusion, dear Messrs. Editors, let me say that your late quotation of "A man convinced against his will," &c., admits of another application, and may be used against yourselves as well as against those who think with—Y. B. A. Z.

[We have never had a doubt, and we still have no doubt, that the Brahma Pootra fowl is a variety of the Cochin-China, and if ever a fact was satisfactorily proved, then the fact is proved that they are only a variety. In the first place we have positive evidence that the variety was produced by cross-breeding between a Cochin-China and a Chittagong fowl, and here let us remark, that cross-breeding is totally different from hybridising. A hybrid is the pro-

duce, usually barren, between two different genera, as between the horse and the ass. A cross-bred is between two species or varieties of the same genus, as between a cart-horse and a racehorse. Hybrids, when they are not barren, usually breed back to one of the forms of the original parents, as when a hybrid is produced between a Linnet and a Canary; but a variety, when not a mere accident, will continue to propagate itself truly. Thus all the Cochin-Chinas breed true, though differing merely in colour.

We accept the sentence as our own, that "If a bird is like another in its form and plumage, they are of the same species;" and we would willingly abide by the decision which any ornithologist would arrive at, who knowing nothing of the dispute, had a Brahma Pootra cock and hen shown to him by the side of a Cochin-China cock and hen of the same age. There may be slight differences in the slope of the back; there may be more meat on the breast (fully accounted for by the Chittagong cross); there may be other slight variations, but these cannot shake any man's judgement who sees the birds side by side, the characteristics of the breed, in form and in plumage, are borne by both.

We see no force in the observation, that the origin of other breeds of fowls is not known, unless it be to strengthen the conclusion as to the Brahmans being a variety, for their origin is known. Nor do we see that the Black Bantam resembling in some respects another black breed, proves more than that the latter may have ministered to procure the colour of the other, just as the Game cock has ministered to produce the Game Bantam; similarly the Chittagong ministered to produce the Brahma variety of the Cochin-China.]

COCHIN CHINAS AT BIRMINGHAM SHOW.

THE report of the Birmingham Show shows a falling-off of £100 in poultry sales compared with last year. This is, no doubt, to be attributed in a great measure to the holders of birds being unwilling to dispose of their best specimens. Capt. Heaton refused £25 per pen for his two first-prize pens of Buff Cochins, and the gentleman who offered this would doubtless have given a higher price, but Capt. Heaton declined to sell; £15 15s., was also refused for another pair of Buff hens; £10 10s., for a pair of Buff pullets; and £15 15s., for a Buff cockerel, and I have no doubt that many other large sums were refused in other classes. These came under my own notice.—C. F. E.

POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

I PURPOSE including in this essay directions for natural and artificial hatching, as well as rearing and fattening chickens, also furnishing plans, elevations, sections, and details of the buildings and apparatus required. In so doing I shall endeavour to avoid all technical expressions, and I shall not touch upon topics which have no immediate concern with poultry breeding from a commercial point of view; but I shall confine myself exclusively to giving publicity to such facts as I have proved by actual experience.

I must, however, caution my readers not to be startled by the novel plan of hatching, rearing, and fattening poultry which I advocate, and of which they cannot find corroboration in any book; and I advise them, before criticising the principles herein put forth, to well weigh all that is stated, and I am confident that every one will admit that they are based upon sound sanitary and scientific laws.

THE NECESSARY APPLIANCES FOR SUCCESSFUL POULTRY BREEDING.

An impression universally prevails that poultry cannot possibly be bred with profit except on farms, and then only when bred in large numbers. This is a mistaken idea, as a few head of poultry will yield proportionately as much profit as any larger number. For instance: whereas, in large establishments heavy expenses are incurred for buildings, rent, machinery, and labour, these charges do not occur with the amateur breeder, who attends to his poultry personally. It is true that large establishments can buy their grain cheaper, and grow their own vegetables; but this, again, is compensated with the amateur, by his obtain-

ing a better price for his eggs or poultry, even if used for his own consumption, than the large breeder, who is obliged to sell his produce through a salesman at wholesale prices.

However, to obtain such satisfactory results it is absolutely necessary to observe certain sanitary laws in the construction of the poultry home, and see that the dietary scale is in conformity with the confined state, and, in fact, providing the poultry with an equivalent of such food as they could pick up when in a free state.

The poultry home I suggest is applicable alike to amateurs and large breeders, and is intended for the accommodation of one cock and six hens for breeding, or twelve hens for laying, and twenty-four half-grown chickens; and as the same principle must be carried out whether in small or large establishments, it follows that where it requires only one home for seven, twelve, or twenty-four birds, it will require 100 homes for 700, 1200, or 2400 birds, and so on, in proportion to the magnitude of the breeding establishment. This plan has, moreover, the advantages of keeping the races and sexes separate, of affording the means of easy inspection, and of extending and multiplying the homes gradually with the growth of the establishment, besides facilitating the labour in feeding and hatching and the sanitary requirements.

Another erroneous idea entertained is that poultry will never thrive well in a confined state; whilst, in fact, they will thrive much better, and be much more productive, than when left roaming about, in all weathers, in search of food, provided the directions given hereafter be implicitly followed. However, it is so far true, that poultry confined in a damp place, ill-ventilated, and not afforded a diet adapted to their confined state, can never thrive. But whose fault is this? Why it might as well be said that a person cannot thrive during solitary confinement, when it is well known that prisoners with a regular diet, comfortable cells, and appropriate labour, soon become very sleek and healthful in appearance, and that in proportion there is less disease and fewer deaths in prisons than among the free population, who are compelled to seek a precarious living in all kinds of weather, and whose home is a wretched hovel, deficient in all sanitary requirements. Moreover, farmers have now for a number of years carried on successfully, in confined spaces, the rearing and fattening of cattle, which are called stall-fed cattle, and which system, although nominally more expensive, is yet far more profitable than the ordinary method; and why should the same system not be extended to poultry?

In general the management of poultry is considered of too little importance, and is left pretty well to chance. It is true that of late years poultry exhibitions have created a taste for poultry breeding; but this is confined solely to amateurs, and what may be called fancy poultry breeding. Yet, amongst all domestic animals, the fowl is, in proportion to its cost or keep, the most profitable and useful; and hereafter I will prove, by figures obtained by actual experience, that poultry can be reared and sold at the rate of 4d. per pound, leaving a handsome profit to the producer. Now, such results, particularly when butchers' meat is 10d. and 1s. per pound, and, moreover, daily rising in price, in consequence of the increase of the population, and the decrease of pasture, ought to prove a sufficient stimulant to the public at large to give a little more attention and consideration to an increased production of such valuable animal food, which, by proper management, could, within a very few years, become as much the food of the poor as it now forms a delicacy for the table of the rich.

However, to obtain such favourable results, it is absolutely necessary to carry out the instructions given hereafter as regards the construction of the poultry home, the sanitary arrangements, and the dietary scale.

A POULTRY HOME

Ought to consist of four separate compartments, exclusive of the glass-covered passage, which runs the whole length of the building, to facilitate the service at all times and in all weather.

- 1st. A roosting and laying compartment, or bed-room.
- 2nd. A glass-covered run, or living-room, in which they can be confined in wet weather.
- 3rd. A hatching-room, or state bed-room.
- 4th. An open run, or park.

THE OPEN RUN.

Starting with the well-ascertained fact that poultry cannot possibly thrive or be kept in good health on damp ground, it becomes necessary, where the surface is not gravelly, to make an artificial dry run. This is best accomplished with concrete, which, besides being cheaper than flagstones or bricks, does not absorb the moisture, and is much warmer to the feet. This run should be formed slightly concave, as shown in fig. 1, and have an incline towards its end, where the rain water can be discharged into a drain communicating with the duck pond.

During summer a few inches deep of gravel, and in winter about 9 inches deep of horse manure, ought to cover the floor of this run, which will afford the fowls ample exercise by scratching and running.

The sides and top should be formed of galvanised iron netting, of about $1\frac{1}{2}$ -inch mesh for full-grown poultry, and 1-inch mesh for chickens.

In fine weather the food should be thrown broadcast in this run, but in wet weather the poultry ought to be fed from feeding-vessels or fountains (see figs. 2, 3, 4), placed in the roosting-room, near the door of the covered run.

Fig. 1.
Transverse section of floor for open run, showing also drain.

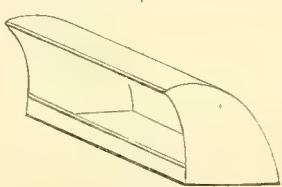

Fig. 2.
Drinking-fountain.

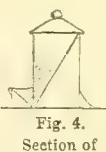

Fig. 3.
Feeding-trough.

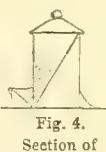

Fig. 4.
Section of feeding-fountain.

Some persons recommend the sides of the run to be boarded to the height of 2 feet, to prevent the cocks of the adjacent runs fighting together. This, however, in so narrow a run, would partially exclude the sun, which is not desirable; besides, cocks, after a few days' acquaintance, become very neighbourly.

The above fountains are constructed on the principle that, when placed with their openings towards and about a foot from the wall, the poultry will be unable to scratch any dirt in, nor can the droppings from the perches fall in.

THE GLASS-COVERED RUN.

The floor of this compartment should be composed of at least 6 inches deep of finely-sifted gritty stuff, such as road dust, ashes, and sand, and on this it would be well to sprinkle occasionally some flowers of sulphur, which would prevent vermin breeding on the fowls. It is the universal belief that fowls powder themselves to get rid of vermin on their body; but such is not exactly the case. The fact is fowls, like all the other feathered tribe, perspire freely, particularly so in the night. This perspiration clogs their feathers, consequently they perform their ablution in gritty dust, on the same principle that human beings do in water, to get rid of the dried perspiration, and to expand their feathers. The same can be seen performed by the birds of the air, who, on a dry hot summer day, make their ablutions in the dust of the roads.

In this run the fowls must be kept close during wet weather, as wet feathers are most injurious to their health, particularly when they are confined.

The sides of this run should be boarded, and occasionally whitewashed. The glass frame forming the roof should be made to open the same as a forcing-frame, so as to admit of free ventilation. A perch ought also to be fixed in this compartment, and the door communicating with the outer run should, in the winter time, be closed at night.—G. K. GEYELIN, Civil Engineer, London.

(To be continued.)

THE LEEDS POULTRY AND PIGEON SHOW.

This exhibition of poultry, though numbering more than seven hundred pens, was doubtless injured materially by the fact that Lord Tredegar's annual meeting was held this year simultaneously at Newport, Monmouthshire. The consequence was that many pens entered by their proprietors for both meetings were finally reserved for exhibition at Newport, not a few owners supposing that the competition would be less severe than at Leeds, and, as a necessary result, the chances of their own success at Newport would be greater. It is really amusing that, after so much previous provision, so many mistakes of judgment should have arisen, for certain it is that in Spanish, Dorkings, and Cochins the competition at Leeds was the very reverse of severe, and the probabilities necessarily are that had they been present at Leeds, pens out of the prize list altogether at Newport might have (in these particular classes), been successful prizetakers.

The arrangements of the pens at Leeds were excellent, and the care taken of the birds betokened rather than they were overfed than the contrary. It should always be remembered that too great a supply of food after long travelling is equally undesirable for poultry as "short-commons;" the want of exercise tending to produce indigestion, more especially in such specimens as are not accustomed to exhibition.

In Spanish fowls Mr. Teebay, of Preston, took the first prizes for both the old and also the chickens; though very excellent birds, they were not shown in the high exhibition trim we have so frequently seen them. Of the remaining Spanish fowls little is worthy of mention, save that one or two pens lost position altogether from the amount of "trimming" that had been adopted prior to sending them. This practice is now unfortunately so prevalent that a portion of our Spanish fanciers seem to think the removal of actually every vestige of feather on the face is an improvement—a mistake the loss of premiums will best tend to remove, and abolish altogether.

The Dorkings of Sir St. George Gore were good, and well shown; but the paucity of Dorkings of even a medium class was painfully apparent to every one.

So many of the pens of Cochins were empty (although the entries were not a few), that it was really a difficulty to find suitable pens to receive the premiums of the Society, these three first-named classes being quite the least favoured in the showyard.

The Game fowls exhibited at Leeds were, however, very good, and the classes well filled. Of all specimens, perhaps, the Brown Reds had the call in their favour, though many of the Black-breasted Reds were extraordinarily good.

In Hamburghs, excepting the Silver-pencilled old birds, it is very rarely we see so good a display—a remark as universally applicable to the classes generally as to the prize birds only. The Spangled varieties of either colour were one of the chief points of excellence at Leeds, the competition being extended throughout both classes.

The Silver Polands were perfect, both old and young ones, and it will be seen to this breed the Society's silver cup was awarded. The Any variety class was an extensive one, and contained many very unusual varieties; the class for Extra Poultry being scarcely less interesting.

DORKINGS.—First, T. Rogers, St. Helens. Second, A. Wilcox, Nailsea Court, Bristol. Third, E. Smith, Middleton, Manchester. **Chickens.**—First, Sir St. G. Gore, Bart., Wirksworth. Second, C. W. Brierley, Middleton, Manchester. Third, F. Key, Beverley.

SPANISH.—First, R. Teebay, Fulwood, Preston. Second, J. Marchant, Halifax. Third, W. Newsome, Leonard Place, Bingley. **Chickens.**—First, R. Teebay, Fulwood, Preston. Second, W. Newsome, Bingley. Third, W. Cannan, Bradford.

COCHIN-CHINA.—First, R. White, Broomhall, Park, Sheffield. Second, H. Beldon, Bingley. Third, C. W. Brierley, Middleton, Manchester. **Chickens.**—First, C. E. Ridgdale, Halifax. Second, Rev. F. Taylor, Kirby Lonsdale. Third, C. Sedgwick, Riddlesden, Keighley.

GAME (Black-breasted and other Reds).—First, M. Billing, jun., Erdington, Birmingham. Second, J. Hodgson, Bowring Old Lane. Third, C. W. Brierley, Middleton, Manchester. **Chickens.**—First, E. Aykroyd, Girlington, Bradford. Second, Capt. Heaton, Lower Broughton, Manchester. Third, T. Briggs, Farsccliffe, Bingley.

GAME (White and Piles).—First, R. Butcher, Chesterfield. Second, A. Robertsaw, Queensbury, Halifax. Third, W. Whiteley, Liverseedge. **Chickens.**—First, R. Butcher, Chesterfield. Second, E. Aykroyd, Girlington, Bradford. Third, G. Wostenholme, Sheffield.

GAME (Any other variety).—First, E. Aykroyd, Girlington, Bradford. Second, G. Wostenholme, Sheffield. Third, W. J. Pope, Barnsley. **Chickens.**—First, E. Aykroyd. Second, Sir St. G. Gore, Bart., Wirksworth. Third, J. Firth, Lilly Lane Mills, Halifax.

GAME COCK (Any variety).—First, E. Aykroyd, Girlington Road, Bradford. Third, W. K. Duxbury, Primrose Road, Leeds. Commended, G. Pounder, Kirby Moorside.

HAMPSHIRE (Gold-pencilled).—First, H. Beldon, Bingley. Second, J. Preston, Allerton, Bradford. Third, S. Smith, Northowram. **Chickens**.—First, R. Hemingway, Shelf, Halifax. Second, S. Smith, Northowram. Third, J. Garris, Wisbey Slack, Bradford.

HAMBURGS (Silver-pencilled).—First, Sir St. G. Gore, Bart., Wirksworth. Second, D. Illingworth, Burley, Otley. Third, H. Beldon, Bingley. **Chickens**.—First, Sir St. G. Gore, Bart. Second, H. Beldon. Third, J. Preston, Allerton, Bradford.

HAMBURGS (Gold-spangled).—First, Sir St. G. Gore, Bart., Wirksworth. Second, H. Beldon, Bingley. Third, J. Walker, Hay-a-Park, Knaresborough. Highly Commended, C. Cowburn, Calls, Leeds. Commended, N. Marlow, Denton, Manchester; W. Birdsall, Meanwood. **Chickens**.—First, J. Walker, Second, Sir St. G. Gore. Third, H. Beldon. Highly Commended, J. Crookes, Hadfield, Sheffield; W. W. Nichols, Sale, near Manchester. Commended, W. K. Duxbury, Primrose Road, Leeds.

HAMBURGS (Silver-spangled).—First, Sir St. G. Gore, Bart., Wirksworth. Second, H. Sharp, Park Road, Bradford. Third, H. Beldon, Bingley. Highly Commended, A. Smith, Woodside, Silsden. **Chickens**.—First, C. Cowburn, Calls, Leeds. Second, Sir St. G. Gore, Bart. Third, H. Beldon, Bingley. Highly Commended, H. Sharp, Park Road, Bradford. Commended, J. Newton, Silsden; T. Fawcett, Northgate, Baildon.

POLANDS (Any variety).—First and Second, and Society's Silver Cup, for best pen of any breed of poultry in the Exhibition. H. Beldon, Bingley (Black Hamburgs). Third, C. Lister, Mirfield (Chinese Silk Fowl). Highly Commended, M. Smith, Branch Cottage, Huddersfield (Malays); W. Maude, Dubb, Bingley (Black Hamburgs); C. Sedgwick, Riddlesden, Keighley (Black Hamburgs); E. Leech, Rochdale (Brahmas).

BANTAMS (Black).—First, A. Aykroyd, Girlington, Bradford. Second, C. Lister, Mirfield. Highly Commended, S. Schofield, Heckmondwike. **BANTAMS** (White).—First, Sir St. G. Gore, Bart., Wirksworth. Second, S. Schofield, Cleckheaton. Commended, J. Crosland, jun., Wakefield. **BANTAMS** (Game).—First, Sir St. G. Gore, Bart., Wirksworth. Second, C. W. Brierley, Middleton, Manchester. Highly Commended, J. Crosland, jun., Wakefield; R. Dodge, Sharrow Road, Sheffield. Commended, A. Robertshaw, Queensbury, Halifax; R. Dodge.

BANTAMS (Any other variety).—First, F. R. Pease, Darlington (Cochin Bantam). Second, J. Crosland, jun., Wakefield (Silver-laced). Highly Commended, T. C. Harrison, Beverley Road, Hull (Silver-jaced); W. J. Cope, Barnsley (Cochin Bantam); C. W. Brierley, Middleton, Manchester (Gold-laced). Commended, J. Crosland, jun., Wakefield (Gold-laced); S. J. Ashton, Mottram (Silver-jaced); F. R. Pease.

GUINEA FOWL.—First and Second, O. A. Young, Driffield. Third, H. Merkin, Great Driffield. Highly Commended, H. Merkin.

TURKEYS.—First, F. R. Pease, Darlington. Second, C. W. Brierley, Middleton, Manchester. Third, A. Heptonstall, Tadcaster.

GEES.—First, O. A. Young, Driffield (Empdens). Second, W. K. Duxbury, Leeds (Empdens). Third, B. Baxter, Elslack Hall, Skipton (Toulouse). Commended, F. R. Pease, Darlington (Toulouse).

DUCKS (Aylesbury).—First and Second, E. Leech, Rochdale. Third, E. Shaw, Oswestry.

DUCKS (Rouen).—First, Sir St. G. Gore, Bart., Wirksworth. Second, A. Cattley, York. Third, J. Dixon, North Parade, Bradford. Highly Commended, S. Pickard, Wakefield; F. R. Pease, Darlington.

Ducks (Any other variety).—First, Sir St. G. Gore, Bart., Wirksworth (Carolinias). Second, H. Beldon, Bingley (Grey Calls). Third, J. R. Jessop, Hull (Wild Ducks domesticated). Highly Commended, J. R. Jessop, Hull (Buenos Ayrean). Commended, J. Dixon, Bradford (Shell-Ducks).

EXTRA POULTRY.—Silver Medal, C. Lister, Mirfield (Rumpless); J. Dixon, North Park, Bradford (Carolina); J. Harrison, Wakefield (Chinese Silver Pheasants); W. Dawson, Hopton, Mirfield (Egyptian Geese). Highly Commended, J. Dixon (Mandarin); W. Dawson, Hopton, Mirfield (Egyptian Geese).

PIGEONS.

In Pigeons no previous meeting of the Leeds Society has been so successful, every class being well represented. A pen of grand Dun Carriers took the silver cup, and well indeed they deserved it. The Powters were also capital. Almond Tumblers were very limited, only two pens being shown, but both good. The Owls were also first-rate specimens. Fantails were shown numerously, but not so clean and good as we hoped for. The classes of Nuns, Barbs, Turbits, and Jacobins deserve special mention. Classes expressly assigned to Swallows and to Magpie Pigeons were, of course, quite new to the generality of shows, nevertheless they were well supported, and with perfect representatives of these singular breeds. The class for Any other variety of Pigeons contained some very beautiful pairs of Pigeons. This class was evidently quite a public attraction, and one of the most interesting in the exhibition.

The weather at the commencement seemed threatening, but on the whole proved more satisfactory as time wore on.

CARRIERS.—First and the Society's Silver Cup for the best pen of any variety of Pigeons exhibited, T. Colley, St. Philip's Road, Sheffield. Second, F. Else, Bayswater, London, W. Commended, C. Cowburn, Calls, Leeds; G. Robson, Brewery, Hull.

POWTERS.—First, W. Ashforth, Loxley Terrace, Sheffield. Second, H. Ramsden, Rose Cottage, Armley. Highly Commended, E. Brown, Sheffield; W. Cannan, Bradford. Commended, S. Robson, Brotherton; E. Brown.

TUMBLERS (Almond).—First, W. Cannan, Bradford. Second, F. Else, Bayswater, London, W.

TUMBLERS (Any other variety).—First, W. Cannan, Bradford. Second, H. Yardley, Birmingham. Highly Commended, J. R. Jessop, Hull; C. Cowburn, Calls, Leeds. Commended, J. Hey, East Parade, Huddersfield. **Owls**.—First, H. Yardley, Birmingham. Second, J. W. Edge, Aston New Town, Birmingham. Highly Commended, J. Hey, jun.

FANTAILS.—First, J. Thackray, Petergate, York. Second, F. Else, Bayswater, London, W. Highly Commended, E. Horner, Harewood; H. Yardley.

BARBS.—First, H. Yardley, Birmingham. Second, W. Massey, Gedney, Wisbeach. Highly Commended, J. Firth, jun., Webster Hill, Dewsbury; W. Cannan, Bradford. Commended, J. R. Jessop, Hull.

TURBITS.—First, F. Else, Bayswater, London. Second, H. Ramsden, Armley. Commended, J. W. Edge, Birmingham; H. Yardley, Birmingham.

JACOBINS.—First, J. Thompson, Bingley. Second, W. Massey, Gedney, Wisbeach. Commended, W. Massey; J. W. Edge, Birmingham; H. Yardley.

TRUMPETERS.—First, F. Key, Beverley. Second, F. Else.

NUNS.—First, F. Key, Beverley. Second, B. Season, Driffield.

RUNTS.—First, S. Robson, Brotherton. Second, J. Wade, Bank, Leeds.

DRAGONS.—First, W. Cannan, Bradford. Second, E. Moorehouse, Haley Hill, Halifax. Highly Commended, H. Yardley, Birmingham. Commended, J. Thompson, Bingley; H. Ramsden, Armley.

ANTWERPS.—First, J. R. Kidson, Burley Lawn, Leeds. Second, H. Yardley.

MAGPIES.—First, J. Harrison, Wakefield. Second, A. P. Leite, Manchester.

SWALLOWS.—First, J. W. Edge, Birmingham. Second, H. Yardley, Birmingham. Highly Commended, J. Hey, Huddersfield.

ANY OTHER VARIETY.—First and Second, H. Yardley, Birmingham (Satinettes and Spots). Highly Commended, A. Brahm, Potternewton (Archangels); T. H. Sagar, Park Lane, Leeds (German Letts). Commended, A. P. Leite (Laced Fantails); J. W. Edge, Birmingham.

Mr. Edward Bond, of Leeds; Mr. John Douglas, of the Agricultural Hall, London; and Mr. Edward Hewitt, of Sparkbrook, Birmingham, were the Judges.

WEIGHTS OF PRIZE POULTRY, AND MATTERS RELATING TO THE BIRMINGHAM SHOW.

I RECEIVE so many letters, and see so many statements, about the weights of prize poultry, that I am tempted to give you the following remarks. I regret to say that last week, only four days after the great Birmingham Show, the Aylesbury drake shown by me, and which was in the second-prize pen there, suddenly died, apparently from no cause whatever, and I found he weighed $9\frac{1}{2}$ lbs. Previous to going to the Show he was upwards of 10 lbs. This is the largest weight, I believe, ever attained by either Aylesbury or Rouen. He was allowed to be, by all who saw him, the handsomest bird ever bred, and was but nine months old.

Let me add a few words about Geese. It was remarked at Birmingham, by many, that no pen of adult Toulouse Geese was from my yard. I had sold my old birds, the winners for four years running, at that show and elsewhere, and which always weighed from 73 to 75 lbs. the three; and I did not think their descendants good enough to win, so I did not send any. Judge of my surprise when I found the winning pen weighed the miserable weight of 37 lbs. the three; whereas my gander alone weighed 34 lbs., and those which I did not send weighed 64 lbs. the three. I mention this that the public may not give undue preference to White over Grey Geese. I cannot understand the judgment about the White goslings. According to your paper the first-prize birds of Mrs. Seamons weighed 57 lbs.; mine, when they left home, weighed 63 lbs., and on their return weighed 61 lbs., and were only commended.

Now as to Rouens. We must all congratulate ourselves on the magnificent show of these splendid birds; and, although they do not attain the weight of Aylesburys, nor are they noted for such early maturity, nor are they such prolific layers, yet their seeming adaptability for most parts of the country makes them justly popular. I must confess I think the Judges very sparing of their favours. There were many pens fit to win at any show entirely passed over, and which I must attribute to the miserable provision made for them by the managers of the Show. Nothing could possibly be worse than the position of all the water fowl. No one could see them except he went down on his hands and knees, and then, from the depth of the pens, the frightened creatures rushed into the farthest corners, and were quite out of sight. Why did not the Committee raise these pens about 18 inches from the ground? this would have enabled all to have been seen.

I would also suggest that in future only a gander and goose, and a Turkey cock and one hen, should be shown: there would be a much larger entry, the Committee would save money in feeding, and the exhibitors a large sum in

carriage; and the other shows through the country would soon follow the example. This is of the greatest importance just now, as I am told the railway companies have ordered that poultry should pay fifty per cent. more than any other class of goods! I must say I think this one of the most monstrous and disgraceful acts on the part of the railway companies that I have ever heard of. It really means that they will put a stop to most of the poultry shows throughout the kingdom; and why they should do this I cannot conceive. I hope you will write down this attempt at extortion, and prevent, ere it be too late, this gross imposition. Here is a capital opportunity for the Poultry Club to show its utility, by raising an agitation, and by its members all uniting in a remonstrance against the project. Already the charges are excessive, and ought to be reduced.—JOHN K. FOWLER,
Prebendal Farm, Aylesbury.

[Not only the Poultry Club, but all exhibitors of poultry, and all committees of poultry exhibitions, should unite in memorialising the directors of such lines as so unjustly and short-sightedly have raised the charge for poultry carriage, request to be informed of the reason why it is so raised, and endeavour to remove the reason assigned. Failing in this, we would have it stated in Parliament as one of the instances rendering it desirable to have the railway monopoly abated; because, let it be remembered that the question of terminating that monopoly in many lines will soon have to be debated and decided by the Legislature.]

OLD COMB.

MR. S. BEVAN FOX in the report of his apiary for 1864, states that the comb in one of his straw hives, although eight years old, "appeared by no means worn out." This shows the wisdom of Mr. Woodbury's advice at page 244 of the Journal, where he counsels us, as a rule, never to "resort to comb-pruning with the view of rejuvenating old stocks."

Seldom, if ever, do old stocks die simply from their combs having become, through age, unfit for breeding purposes. At all events I never met with a case, and I have seen some very aged hives.

Those managed on Nutt's system and in which swarming has been effectually prevented, are in a few years left with aged and effete queens, which besides being unable to keep the population up to the mark, may perish in winter or at a time when their loss cannot be repaired.

Those old stocks, again, in which swarming is allowed, are left with the younger queens, and if the season is advanced or proves wet and unfavourable, they may meet with an accident in their wedding flight, or through impregnation being retarded, turn out drone-breeders, and thus bring ruin on their hives. Besides, stocks which give out swarms are sometimes left with a very small population at the close of the season, and are, consequently, unable to bear up against the rigours of winter. In addition to these evils the stores of old stocks which have given out swarms are often greatly reduced, not only by what the young brood has consumed, but by what the swarms have carried off. I, therefore, regard, not comb old and unfit for breeding purposes, but paucity of numbers, poverty of store, and accidents of one kind and another as the destroyers of old stocks. I have seen the bees demolish 3 or 4 square inches of old and unfit comb composed of worker-cells, and insert comb with drone cells in its place. I say then, with Mr. Woodbury, As a rule, leave the bees to themselves to renew their aged combs.—R. S.

FOUL BROOD.

It is certainly most singular that the position of pupæ in foul-breeding stocks should be found reversed. Whether such peculiarity may yet afford a clue to the elucidation of the greatest of all aparian mysteries—foul brood, or is simply a distortion of weakness or approaching dissolution, a turning of the face to the wall, as it were, remains yet to be explained.

In the black stock sent "A DEVONSHIRE BEE-KEEPER" last year to be ligurianised, ere yet he had discovered the cause of his "dwindling apiary," and which had been infected from his Ligurians, he informed me of having discovered, on cutting up a royal cell, a defunct princess in this novel pre-

dicament. I looked on the matter at the time, as very possibly did my esteemed correspondent, as purely accidental. On foul brood showing itself generally in my apiary in the end of last season I was very much puzzled at finding worker brood so placed, and on making a renewed acquaintance with this vile scourge this season paid particular attention to this, and invariably found the diseased grubs reversed, the only stray exceptions to the rule being defunct embryos that had evidently advanced a stage or two further before their demise, and were, besides, not in so foul or rapidly decomposing a condition.

Noticing that the attention of the Entomological Society has been directed to this subject, it would be of the highest importance to apiarists generally were some member of that learned body to take up and investigate the point—say by making a daily microscopic comparison during the coming season of the evolutions of the pupæ from the egg upwards, in a diseased and healthy stock, thereby detecting the exact stage, if not the cause of the change of posture and demise.

The above allusion to this season's experience of foul brood reminds me that my contributions to the aparian corner of "our Journal" have fallen grievously behind, and if occupation with other matters do not supervene, some older jottings may be pardonable during the dormant season, when, generally, there is a greater lack of more stirring events.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

To POULTRY BREEDERS AND THE TRADING COMMUNITY GENERALLY.—Has any one had dealings with a person calling himself Thomas Andrew, writing on letter paper headed Andrew Brothers, African Merchants, 48, Dale Street, Liverpool, and what was the result?

CROSS BETWEEN WHITE COCHIN-CHINA AND SILVER GREY DORKINGS (W. T.).—Never having seen the progeny from this cross-breeding we cannot give an opinion upon them. We should expect them to be good table fowls.

BRIGHTON SHOW (T. C. H.).—You will find a notice of this show at p. 483.

DARLINGTON POULTRY SHOW.—Mr. Kershaw, Ashton-under-Lyne, informs us that his Cochin-China cock (any variety) was "highly commended" at this Show.

WHITE BANTAMS (J. W.).—We most unhesitatingly say, Select the small birds. We hardly know what to call good ears, as the white ears are not imperative in them, as in Black Bantams. Where other points are equal, there can be no doubt whatever that smaller size should turn the scale in favour of the birds exhibited.

TAIL OF PARTRIDGE COCHIN-CHINA COCK (Cochin-China).—One or two white feathers are not a disqualification. It is common in old birds. The only feather-disqualification is red, or blotched breast.

BRAHMA POOTRA PULET STAGGERING (Country Rector).—Administer castor oil freely, in doses of a tablespoonful. If this fail, you may bleed from the comb, but do not cut off any of the points or serrations. Feed entirely on soft food, as bread, meal, &c.

VARIOUS (Rouen).—You must choose your breeds. Brahmans, Spanish, Cochins, and Crèves Coeurs, and also La Flèche, will do well in a small space. You do not say you mean to rear chickens. If you want only eggs you will not require to change your cock. If you wish to breed only Brahmans you must keep with them Crèves Coeur or Spanish; they lay white eggs, the Brahmans brown. Give them as much sun as you can. If your yard is paved, cover it with loose gravel an inch or two deep, and supply them with turfs, cut with plenty of mould. No bird bears confinement worse than a Dorking. Three, or at most four Ducks, are enough for a drake. They do not require to be fattened from the time of hatching; but a bird that is intended to be a winner at some time must always be kept in the highest condition, and may be put up for a fortnight before it is sent to a show, for the purpose of increasing weight. A Duck is never in better condition than at ten or twelve months old, but she often gets heavier as she gets older.

PROFITS OF POULTRY-KEEPING (R. F. E.).—Poultry-keeping, on a small scale, will help a man to live, but will not secure a living, we think; but we commence a series of papers on the subject to-day. New-laid eggs in the winter are very profitable.

WEIGHT OF BANTAMS (E. H.).—There is no fixed weight for any but the Sebright Bantam. These should not exceed—cock, 17 ozs.; hen, 14 ozs. A Bantam cannot be too small. The hen is out of condition. If she wants medicine, give castor oil. The appearance you speak of is indicative of poverty; feed well, and, as the laying season comes on, the comb will be red.

EARLY BAOD ON SILVER-PENCILLED HAMBURGS (Poultry).—Let your chickens have good sound, and not weak beer to drink. Give them goats, bread and milk, cooked meat chopped fine. Feed them after dark and before daylight by candlelight. Always recollect you have sixteen hours night to eight of daylight, and you must lessen the consequences by late and early feeding. Let the rip with the hen under it be in a sheltered and dry place. Let it be warmed, but it does not require to be artificially warmed. The later they are fed at night the less necessity there is for early morning feeding.

PARTRIDGES.—On the 7th inst. some amusement was created in the quiet little market town of Lutterworth by a covey of five or six Partridges alighting in the centre of the town, causing an immediate scramble amongst those persons who happened to be in the street. Nor is this a solitary instance—on the Wednesday previous one bird was captured in the same locality, and on Sunday last two more were also taken. Can you give me any information as to the cause?—A SUBSCRIBER.

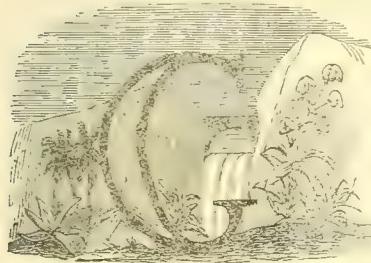

[Excessive terror from being pursued by a hawk was the probable cause. A Pheasant about three years since was flushed before the County Hospital in the centre of Winchester.]

WEEKLY CALENDAR.

Day of M'nth Week.	Day of Week.	DEC. 27, 1864—JAN. 2, 1865.	Average Temperature near London.			Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 43.2°, and its night temperature 31.5°. The greatest heat was 58° on the 28th, 1855; and the lowest cold, 1° below zero, on the 28th, 1860. The greatest fall of rain was 0.70 inch.

PLANTING AND TRANSPLANTING.

ENERALLY speaking the removal and planting of trees and shrubs is an operation to be performed in the months of September, October, and November, according to orthodox rules. But, then, as regards

myself, I happen to be one of those selfwilled individuals who follow no conventional rules in connection with garden operations, and as gardening is a matter of business with me, the fraternity will probably stigmatise me as perverse and headstrong. Be that as it may, whenever I find it desirable or necessary to remove and transplant trees or shrubs, and I have a convenient opportunity, I put aside all considerations as to the time of year, and submit only to the negative dictates of frost and much wet. I have transplanted trees and shrubs in the middle of summer and in the middle of winter, in spring and in autumn, the after-treatment, of course, being influenced by the weather, and never have I found that the success or failure of the operation could be directly or indirectly traced to the mere season of the year at which it happened to be performed.

This assertion may be diametrically opposed to the opinions of many of the most able and experienced gardeners, I nevertheless adhere to it, and even deny that the best time to remove trees is when there is plenty of moisture in the ground; in other words, when there is sufficient moisture in the soil to cause it to hold together in solid spits. I like it best when it will crumble, and run in among the fibres and roots, and this I find it will do best in the summer time, when the ground is comparatively dry. Much, I am aware, depends on the nature of the soil, and if it is naturally crumbly and light, probably the best time to plant trees in it is the autumn or winter; but even this I will not venture positively to assert, for I have invariably found that, no matter what the soil is, newly-planted trees are likely to do best when the roots start into action immediately after planting. This is certainly not done in the winter, unless the season happen to be unusually mild; and although the trees may sustain no injury from remaining a long time inactive, it does not disprove what I affirm.

Some years ago I assisted in removing a number of evergreen shrubs from one garden to another: they were taken two or three at a time on wheelbarrows to a distance of about half a mile, and the weather was both hot and dry, the period of the year being about midsummer. As each was planted a basin was formed around it, the soil being in a crumbly state. This basin was filled up twice with water, which seemed to run the soil in amongst

the roots, and leave them as though they had never been removed. They took to the soil immediately, and I never knew fresh-planted shrubs do better. I thought at the time that it was incurring too great a risk, as the shrubs were fine specimens; but the result proved that all my fears were groundless, and if since then I have had occasion to remove trees or shrubs at any period of the year I have never hesitated to do so. The weather subsequent to the operation will suggest such precautions as are necessary to insure safety—that is, in the way of shading, syringing, mulching or watering, and staking in case of high winds. These precautions are often necessary, and the neglect of them is more frequently the cause of failure than the supposed wrong time of the year.

I would not, however, have it understood that I am advocating summer planting in preference to autumn or winter planting. There are cases in which it would be entirely out of the question to perform such operations in the summer on account of the pressure of other work; nor does what I assert affect this matter in the least. What I would recommend is not to be bound by usage, nor to be led by would-be clever theorists, who describe minutely how the tree should be taken up, how the hole should be dug, how the soil should be trodden over the roots, the month, the week, or even the day on which transplantation should be performed, and such matters of detail as are far better left to the discretion of the operator.

Many gentlemen lay out large sums of money in the purchase of trees and shrubs, and make extraordinary mistakes in the planting and disposition of them, simply, it appears to me, for want of a few practical lessons, and partly, perhaps, from being unacquainted with the nature of the trees which they plant, or their knowledge being confined to the simple fact that trees should be planted with their roots downwards. This is rather a limited knowledge of vegetation; but judging from the manner in which many trees are treated one would think that it was also the extent of the knowledge possessed by the planter. For instance: a gentleman owns a field or paddock, and desires to have a belt of trees round it. He goes or sends to a nursery for one or two hundred young forest trees, and they are planted, the turf being replaced close around their stems. While the owner is congratulating himself on the pleasure he will experience in soon having a plantation of vigorous young trees, some of them are dying, and the rest do not grow. How is this? The nurseryman who supplied them is blamed; it must be his fault in supplying bad trees. What else can be the reason? Trees are pointed out as growing vigorously in neighbouring fields, with the grass extending up to their trunks, just as he would like his own to be, and he cannot see why they should not. Now, I would simply inform him that the grass growing under an old-established tree is merely there on sufferance, the tree has the mastery, and will not allow the grass to attain more than a certain degree of strength; but with fresh-planted trees the case is different, the grass pushes out fibres long before the tree, and the roots are down among those of the tree before the latter have made a single fibre.

In fact, the grass abstracts all the moisture from the ground at the time of the year when the tree requires it most, so that the latter is left to starve, consequently it does not grow. The gentleman, however, cannot see this, and blames the nurseryman; but if he will take a useful hint, and look nearer home he will find the remedy. When the trees are planted let the ground be kept bare of herbage as far as the roots extend, and this until the trees are thoroughly established.

In another case the trees are planted in gravel or sand, and in this they cannot grow from want of nutriment. The nurseryman cannot very well be blamed in this case, for the cause of failure is obvious, and the want of success is at once attributed to it. In consequence of this discovery the owner orders the surface of sand or gravel to be removed, and two spadesful of strong manure to be placed close to the stem of each tree; or he orders each to have half a pailful of good strong liquid manure; so they are poisoned, and eventually succumb to their fate. Possibly the gentleman employs a gardener, who well knows that liquid manure beyond a certain strength will injure, perhaps kill, his Cabbages, and he will possibly suggest that the stuff might be a little too strong. Well, then, the gentleman will buy more trees, and treat them to liquid manure in a weaker state; but even then somehow or other they do not grow. Now, I would suggest that newly-planted trees have neither the mouth to imbibe nor the stomach to digest liquid or even solid manure, and that trees require plain soil to fibre into; consequently if a good-sized hole had been made in the gravel for each tree, this filled up with common soil, and the trees planted in it, they would probably have done well, and, when established, pushed their roots into the gravel, and derived a certain portion of nourishment from it.

It must not be supposed that I have merely pictured imaginary possibilities; for I have seen instances of what I have described, and have known gentlemen purchase valuable shrubs and trees to plant on their lawns; but, as a rule, the practice has been to lay the turf close up the stems after planting. Two-thirds of those which I have known treated in this way have either died or barely existed, and this I can ascribe to no more likely cause than replacing the turf over the roots. I have frequently taken off the turf round coniferous and other trees, removed some of the soil, and have noticed that in almost every instance, except after continued rains, the ground has been hard, dry, and seemingly impervious to any amount of rain. It is evident that such are not the conditions in which a tree could be expected to grow and flourish; it is worth while, therefore, to take a lesson from the fact, and in planting trees, especially those which are valuable, to leave the surface of the soil bare for a certain space round the stems when they are planted on lawns. Let a neat circle be cut in the turf, and the appearance will be quite as good as if the turf had been laid close to the stems. This will go far towards insuring the safety of the trees both by permitting rain and artificial waterings to sink down, and saving the trees from the drying and exhausting influence of the grass, which takes up the moisture for its own support.

There are other circumstances in connection with planting trees and shrubs which it would be worth while to notice, for it is astonishing how little attention is given to the subject by a large number of gardeners, young ones in particular, who apparently consider it a matter scarcely deserving more than a passing thought. Numbers of trees are thrust into the soil with torn and bruised roots; others are buried much deeper than they ought to be; many have the soil thrown in solid lumps on the roots, this being often trampled and trodden until it becomes as hard and solid as it is possible to make it, as though planting a tree were an operation differing in no respect from setting up a post or scaffold-pole. Then, again, fresh-planted trees are left all the winter to sway and twist about with the force of the wind, which alone would prevent the roots taking hold of the soil. These and other shortcomings are not at all uncommon, and appear to result from a thoughtlessness that in effect is as culpable as wilful carelessness or neglect. The old axiom, that "what is worth doing at all, is worth doing well," applies in all its force to planting trees; for it is by no means pleasing to the owner nor creditable to the operator when, after planting a number of trees or shrubs, a

large per-cent of them die, leaving ugly gaps, which must be, and are, eyesores to all who behold them. The neglect of such precautions as are necessary to insure success cannot be excused on the score of taking up too much time; for to plant a tree well, and as it should be, does not take a minute longer than to plant carelessly. There are, it is true, causes of trees dying which are not always under the control of the planter, and for which a certain allowance ought to be made; but, then, it is undeniable that careless planting is productive of more failures than any other cause that I am aware of, and this must be my apology for offering these remarks.

What I have said refers more particularly to that class of gardeners who have no under gardener or other assistance, and many of them perform such work as planting in a manner far from creditable to themselves or the vocation which they assume to represent. It is not too much to assert that nothing can be of more consequence, as a rule, than the success or failure of fresh-planted trees, since they are ever before the eye, and criticised by employers and visitors. The character of the planter is, consequently, involved, and it would be well for him to give his attention a little, or, rather, much, to the art of planting, and not be contented simply with relying upon the facts that a hole must be dug, the root of the tree placed in it, and the soil returned and trodden over. Any labourer knows that much, and can do as much; and if the gardener desires, as he should, to receive credit for a little more understanding, he must show it in the way he performs his work.—F. CHITTY.

FLOWERS OF THE PAST SEASON.

GREENHOUSE PELARGONIUMS.

WHEN the objection is made that flowers are being continually brought before the public which are no improvement on kinds already in growth, there are a few things to be considered before condemning the raisers and distributors. The perfection to which many of our most favourite flowers have been brought is such, that a very slight improvement is often all that we can hope for in the colour or form of the flower; but this improvement is often combined with an improved style of growth, which greatly enhances the value of the variety; and this is a step greatly needed in some of our best flowers even yet. Thus, one of the very finest Pelargoniums of the past season—Achilles, has in point of colouring reached a climax which can hardly be surpassed; but then its style of growth is such that it is impossible ever to make a good plant of it. Raisers must, then, try if they cannot get such a flower on a robust style of growth. Then, again, some varieties are over-robust. The foliage is so coarse, that, although the blooms are good, yet they are either too sparingly produced or else smothered by the foliage. When I make such observations I have not in my mind the needs of exhibitors, but of the general grower. A painstaking trainer can make an exhibition plant in course of time out of almost anything, even as Sergeant Hopkins will, if you only give him time, convert the veriest Johnny Chawbacca into a smart and well-set soldier; but amateurs who never think of exhibiting, and yet who desire to have a good show of Pelargoniums, do want to know which are those best suited for the home stage, and it is their wants that I would ever bear in mind—exhibitors can and will take care of themselves.

As usual, Messrs. Hoyle, Foster, and Beck have supplied the new flowers; the productions of the two former going to Mr. Turner for distribution, and of the latter to Mr. B. S. Williams. I have had, thanks to them, the opportunity of seeing their flowers in my own little greenhouse, and of taking notes from day to day of their qualities. In this way a more satisfactory conclusion can be arrived at than from a mere cursory glance at an exhibition or in a nursery; and although it is very possible there may be mistakes in the following lists, yet the remarks are made according to the best of my ability, and may, I think, be depended upon.

MR. HOYLE'S.

These deserve the first place, for unquestionably he is the best seedling-raiser that we have, and his flowers always appear in large numbers in every winning set of exhibition

plants, and, moreover, amongst his lot were decidedly the best flowers of last season.

Artist.—A very fine large flower. Upper petals very dark; lower, a clear bright rose; white centre. A bold-looking flower, and the habit of the plant good.

Achilles.—A flower of the most brilliant colouring, orange ground, strongly marked; upper petals dark beautiful maroon with fiery crimson edge. Habit of plant very weak, difficult to grow.

Diadem.—A rosy purple flower, and with a deeper shade of colour in it, with a bright white centre. Quite a novelty in this shade of flower. Top petals very dark, narrow border of bright carmine. Habit of plant good. A first-rate flower.

Emmeline.—Orange rose lower petals; very dark maroon top, margin of bright carmine.

The Prince.—Clear rich orange flower, white centre; top petals maroon, broad border of carmine. Very free-flowering, and of good habit.

Royal Bride.—A white flower; top petals, large deep blotch, narrow bright border. No improvement on other similar flowers as far as my judgment went, and in that of a friend and neighbour whose opinion on these points is worth having.

Amy.—Peculiar shade of purple, with very large trusses, but a gross habit of foliage, which detracts from its value.

Alexandra.—A shaded lilac rose flower; top petals bright scarlet rose, with small blotch. A novel-looking flower of good habit.

Lord Eversley.—Very free flowering; of excellent quality and rich colours. Light centre; top petals bright maroon, with narrow shaded margin.

Cherry Ripe.—Bright rosy orange; centre white. Very fine. Blotch not very dense. Good habit.

Phantom.—Lower petals rather long, white throat; flowers somewhat loose, but striking in colour.

A few of Mr. Hoyle's flowers I had not the opportunity of seeing, so cannot say how they have turned out—such as Aristides, Peerless, Penelope, and Philo. Of those enumerated above the best are unquestionably *Artist*, *Achilles*, *Diadem*, and *Alexandra*. *The Prince* and *Lord Eversley* are well worth growing.

MR. FOSTER'S.

Belle of the Ball.—A strongly-coloured painted flower; somewhat long lower petals; top petals quite black, margin rose; eye white and clear.

Rienzi.—Painted carmine lower petals, black maroon top petals; narrow crimson edge.

Princess Helena.—A little rough. Very dark, in the style of *Topsy*. Lower petals painted.

Miss Burdett Coutts.—Rose-coloured flower, not of first-rate quality.

These flowers have all, more or less, the fault which I have always found in Mr. Foster's flowers—that they are not sufficiently broad in proportion to their length, and which I have no doubt excludes so many of them from the exhibition stage; still they are improving, and with a little foreign blood infused into them would be much better. They are very rich in colour, and their habit is generally fair, so that there is only this change needed. *Belle of the Ball* and *Rienzi* are the best of those named.

MR. BECK'S.

Display.—Very dark heavy spot; nice dwarf habit, but somewhat too long in the petals.

Maggie.—Pretty light spot; very free flowering; shape good, and habit very dwarf. An excellent variety.

Princess of Wales.—Bright rose colour; very bright, but not constant.

Spotted Nonpareil.—Excellent dwarf habit; free bloomer; the colour bright and rich. An excellent variety.

Hector.—Good smooth flower; colour bright rose, white throat, dark shaded spot; habit good. A very pleasing flower.

Diana.—Habit of the plant dwarf; lower petals painted; top petals very dark, with margin of scarlet rose. An excellent variety.

Paris.—Smooth flower, but common in colour, and in no respect remarkable.

The Charmer.—A nice, smooth, rose-coloured flower of fair average properties.

We have already had some very excellent flowers from Mr. Beck, and some of the above are in habit all that we want, the growth short-jointed, plants "stocky," as the phrase is, and the bloom freely produced. The flowers may not have, perhaps, quite that refinement (I know of no better term to use), that Mr. Hoyle's have, but they are some of them such as an amateur will delight in for their style of growth. As far as I could see *Maggie*, *Spotted Nonpareil*, *Hector*, and *Diana* are varieties that will be found well worth growing, and will keep up the credit of Mr. Wiggins, who has given us many very beautiful varieties.

It is impossible not to see that the *Pelargonium* is still amongst our most favourite flowers, although, from the present style of exhibition, the same plants are too often, from year to year and from show to show, placed before our eyes. If more encouragement were given to smaller plants, I am persuaded it would be more popular than ever; it possesses so many advantages, is so easily grown, is so free-flowering, and continues for so long a period in bloom, that from cottage to palace it finds a home; and it is quite a pleasure, in our neighbourhood at least, to see how the old worthless kinds in cottage windows are being displaced by better and newer varieties. Again are there new candidates for public favour, and amongst them probably the very finest *Pelargonium* ever raised, John Hoyle. On these I hope to report in due season.—D., Deal.

HOUSE SEWAGE.

REMOVED as I am from the great centre of practical thought and speech, I appear to myself as a humble worker upon the outskirts of the earth, creating in my little sphere motives for my own forces to exert themselves on, and occasionally using the press as my safety-valve. I find it a great blessing thus to be able to occupy my mind independently in a little exclusive borough, where scarcely a neighbour feels sufficient interest in one's proceeding to wish one good speed, nor inclined to take any advantage from my undertakings for their personal interests. Mr. Fish in his "Doings," expressed a wish that I would further enlarge upon the subject of sewage soon after I wrote about it in May last (Vol. VI., page 365). I will not repeat what I then said, but as the question is very important to the country, and is becoming very popular, as well as out of regard for the request of Mr. Fish, I willingly take it up. A few words as to the past. It is thirty years since (I was then a boy), the great utility of sewage and liquid manure became impressed upon my mind by accident. I have, with but a few years' intermission, used it ever since, and fifteen years ago, in my first article in this Journal, I touched upon the utility of sewage, and I have every year since adverted to the subject, both in these columns and in those of four other periodicals.

To help to reconcile opinions, I think it well to send some specimens of our fruit for you to pronounce on, and if you find that it possesses any quality worthy of mention, you may chiefly attribute it to the supplies of sewage which the trees have been accustomed to receive. I could not arrive at flavour in this soil, even when I had twice taken up the trees experimentally and changed its texture. Till the happy idea of sewage came to aid me Pears were scarcely equal to Turnips, and the Apples were on a par. It is seven years, I think, since I first sent you some of the same sorts from the same trees to taste, in consequence of the improvement in flavour after the first summer's supply of sewage, and the trees have never since had any other manure, for we keep neither horses nor pigs, and dung is very expensive.

I feel that I cannot take so firm a grasp of my subject as I could wish, unless I revert somewhat to the state of this garden on my introduction to it. From inquiry I found out that it had long been considered a piece of ground quite worn out, and occasioning more expense to cultivate than it was worth. It had been upwards of two hundred years under fruit and vegetables, and the miserable specimens which I saw and the appearance of the whole were so different from what I had been led to expect, that any person not accustomed to look beyond the surface would certainly have been disheartened. To examine the subsoil was my first proceeding. I found that it had never been disturbed since the garden was made, and, consequently, that the soil

in time could probably with honest treatment be brought back to what it was at first, a sound gravelly loam. About 3 feet deep a natural clay presented itself, and this made me decide at once for drains. It is now seventeen winters since, reckoning in the present, a re-arrangement of the ground took place and it was drained; plain-trenched I cannot say that it was, for what with new fruit-borders, shifting walks, and so on, a great body of soil was removed to new positions. Care was taken to keep the bottom spit down as much as possible. Rotting wood and débris, the accumulation of several years, and famous as a preserve for rats, were cleared out of the back yards, and added as the completion and planting went on, and this was all the manure afforded. Just before sowing-time next spring soot and salt were applied as a top-dressing, and the greater part of the ground was cropped with Potatoes. The result was upwards of two hundred sacks per acre, of a sort of Kidney much grown about here at that time, excellent as a cropper but worthless to eat.

This example serves to show the beginning of a principle upon which old gardens can be renovated, and let me add, all holdings, be they great or small, agricultural or horticultural. For my own part rather than allow the excuse of want of dung to distress me, I would delve into and break up the most uncongenial subsoil as a means of compensating for the want. I had no liquid-manure tanks here, neither from the state of affairs with which we had to contend for some years would the idea of making them have been entertained; but as time rolled on hard cropping began to tell once more on the soil, and the knowledge that the nourishment which it required was running daily away to pollute the river, caused the masons to be set to work to form a tank. From one, in due course, we advanced to two, and also two large soft-water tanks, which catch the rain that falls on the roof of the house and outbuildings; and, as if human nature were never satisfied, I want another of each kind. The ground here has never shown any signs of exhaustion since I have used the sewage; of course it also receives the decayed vegetable matter, tree leaves, and other rubbish annually collected on the premises, with the addition of the decayed manure of a two-light hotbed judiciously applied, occasional dressings of lime rubbish, or a few bushels of quicklime, and the sweepings of chimneys. Still these additions would not be nearly sufficient to keep the soil productive without the application of the sewage.

Having arrived at this point, I will now try to describe the manner in which I apply the sewage to the land, and in order to do so intelligibly, I have taken measurements, and made calculations, the results of which will, I hope, come within the comprehension of the least informed of my readers, and meet the wants of the smallest operator.

I will take as my basis an area of 44 square yards of turf, covering the roots of our largest Apple tree. Our largest sewage tank holds 850 gallons (not including the unpumpable sediment), which would weigh about 4 tons. Our hand-waggon holds 30 gallons, and by this I have been enabled to know the exact quantities I have allowed for the above space. Three hundred gallons of sewage to the 44 square yards is as much as this soil will carry, and I avoid driplets as I would the plague. Except with light, sandy, and gravelly soils, one can pretty well judge when the ground is thoroughly saturated, for then the water will run from the surface.

I withhold sewage from fruits and vegetables till such time as they most require it. I give it to the Cabbage family, and all succulent plants at periods from their young strength up to production; to the pod-producers from their midgrowth up to the last gathering; to fruit trees in the open ground as soon as the fruit is set and established upon the trees, and again when it is half grown; to Vines from the time of the berries setting up to the first indications of colouring; to orchard-house trees in pots from the fruit being well established up to the first signs of its ripening. I give a good soaking once a-week; and this applies with me to flowers in pots, even up to the time of their ceasing to bloom, and to Roses, evergreen shrubs, and deciduous trees down to the Filberts, or to any spare ground during the winter, and according to the amount of sewage manure at command. For fruit-borders, previous to the application, I slightly fork over the surface, and for turf under Apple

trees I ply up the surface with the same implement gently, to allow of the sewage sinking in, and prevent its running off by the surface.

On the supposition that 300 gallons of sewage have been given to our Apple tree a week or so after the falling of the blossom, and that the Apples are beginning to swell, when they sorely tax the tree for nourishment, then apply 300 gallons more, and so that the extremities of the roots may receive the greatest share. The quantity will then, in two waterings, have amounted to 600 gallons to the 44 square yards of ground, and that is the proportion which I allow, whether the space be large or small, using judgment, however, and having regard to the thorough saturation of the soil, of course, making allowances when this is in a wet state. I water with the sewage in a dry time if possible, and on the third day I work over the surface of the soil with a scratch-trident, for if this operation were neglected the moisture would be rapidly evaporated. Though we may be sure that the soil would not part with any of the manurial particles added to it by the sewage, let it filtrate downwards, or evaporate upwards, still the condition in which its nutritive properties are most available to the spongioles of the roots is when the soil is kept open, warm, and moist.

Now, as 44 square yards are to 4840 (the number of square yards to an English acre), so are 600 gallons to 66,000, or 310 tons 11 cwt. 3 qrs. 20 lbs.—say 310 tons 12 cwt. From chemical analysis I learn that 1250 tons of London or Edinburgh sewage are equivalent to 1 ton of Peruvian guano, the present market price for which would be, I believe, £13 12s. 6d. per ton. Then, according to the above calculation, 310 tons 12 cwt. of Woodstock sewage would be equal to 4 cwt. 3 qrs. 20 lbs. of guano, and in value to £3 7s. 1d. per acre, presuming the Woodstock sewage to be equal in strength to that of London or Edinburgh. I have no reason to believe that it is less so; for the sewage of this house does not become intermixed with waste water, every drop of which is made use of for some household purpose before it enters the tanks, which also receive the excreta from the closet, and soapsuds. The quantity of sewage from this small establishment that I have distributed to the garden in the last twelve months has been 8250 gallons, weighing 33 tons 16 cwt., calculated to be equal to 2 qrs. 13 lbs. of guano, worth 8s. 4d., which cost rather staggers one by its insignificance, when the immense results that we have derived from it are taken into consideration. It is quite evident that there must have been other manurial agents at work in the sewage, besides that equivalent in guano in a liquid state, fit to be absorbed by the young rootlets of the plants and trees. At any rate I consider the system is paying us fifty per cent., notwithstanding that our sewage waggon has recently had a new bottom, and the pump-bucket and hose require repair.

As respects deodorisation, I require but little assistance, as the sewage here is seldom allowed to remain long enough to become offensive; and I generally, during the summer time, give my sewage-waterings in the evening, and by next morning I find that the bad smell has almost disappeared, in consequence of the gases being absorbed by the soil. Connected with one of the tanks, however, there is a drain leading direct from the scullery, and, there being no stink-trap, I generally use a disinfectant, for the house-servants complain of the effluvia in the kitchen; and, what is worse, they complain of Mr. McDougall's disinfecting powder, which I have for a long time been in the habit of using; they declare it has a pitchy smell of its own worse than that of the sewage. I used the box of powder which was sent to me from your office early this spring as a disinfectant for the tank and drain in question, and it immediately took away all bad smells, and left none of its own. I really wish I could find out whence it was obtained, in order that I might procure some more. I think you informed me that Mr. Fish had a box of this powder sent to him. Did he try it? A half-peck or so, qualified by a bucket of water, as we do soot or lime, to be stirred into 600 gallons or so of sewage a few hours before making use of it, and then the utensils dusted with the powder through a coarse dredger after they were used, completely destroyed the bad smell. I use McDougall's powder now in the manner described, and I do not know of its equal for the purpose, excepting the powder above mentioned. Mr. McDougall, for

his sewage works at Carlisle, I read, uses a liquid disinfectant; it may possibly be a better ingredient for the purpose than his powder.—**UPWARDS AND ONWARDS.**

HAGLEY HALL.

THE SEAT OF LORD LYTTELTON.

A PLEASANT walk of a mile from Stourbridge led to the lodge gates. Having entered the carriage-drive a portion of the diversified scenery of the park is seen on the right; turning to the left by the stables, visitors are requested by a notice on the gate to proceed through the small pasture field, and ring the bell at the garden entrance.

On entering is a small flower garden, gay at the time of my visit with Scarlet Geraniums, Calceolarias, Verbenas, Lobelias, &c. A large Juniper, its drooping branches loaded with red berries, was likewise an attractive object. Further on is the kitchen garden of six acres. The first house we entered was the stove, which contained good specimens of Stephanotis floribunda, Bignonia venusta, and the usual assortment to be seen in such places. There were a Cucumber-pit 50 feet long, a viney 50 feet long, containing good bunches of Black Hamburgh and White Nise; a Peach-house, 30 feet long by 15 wide, with fine healthy trees of Grosse Mignonne and Noblesse. A fruit of the latter weighed 10 ozs.; and Mr. Mackie said it was but little more than the average weight of every one on the tree. A second viney, 30 feet long, contained fine bunches of the Barbarossa, a favourite late Grape here. The plant-house, 30 feet long, was filled with Camellias and a good collection of Chrysanthemums. The fruit-room contained a choice assortment of Pears and Apples, such as one can only expect to see in Worcestershire, and a few other localities favourable to their growth and maturation. The Dahlias were worthy of notice for their size, beauty, and constancy. The best, where every one was good, were Bob Ridley, Dodds' Minnie, Triumph, Dr. Hogg, Garibaldi, Lord Russell, Mrs. Crisp, Warrior, Mount Vesuvius, Merrivale, and Loveliness. In the pleasure-grounds are noble clumps of Rhododendrons, and a large specimen of the Pampas Grass. A summer-house, with stained-glass windows, represented the seasons, as described by Thomson; and among the forest trees was a Larch that measured 11 feet 3 inches in girth 3 feet from the ground, and having a straight bole 50 feet high.

It may be interesting to the reader to know that this beautiful park and grounds, of about one thousand acres, were laid out by the first Lord Lyttelton, assisted by his friend Shenstone. We are told that the manner of laying out ground in the natural style was quite in its infancy when Shenstone began, about the year 1750, to carry out his ideas of rural elegance, and by degrees he brought his own place, The Leasows, to such perfection that, long before he died, his little domain had not only attracted the notice and procured him the acquaintance of persons the most distinguished for rank and genius, but had become the envy of the great and the admiration of the skilful—a place to be visited by travellers and copied by designers.

The first object that attracts attention in the park is the Grecian temple, situated on rising ground; then a pedestal dedicated to Thomson, with a Latin inscription. The next is Jacob's well, with the rectory-house, on the brow of a distant knoll, partly visible through the trees. Further on is the dingle, with a rivulet meandering through the valley; then another testimonial of friendship, with the following lines—

To the Memory of
WILLIAM SHENSTONE, Esq.,
In whose verse
Were all the natural graces;
And in whose manners
Was all the amiable simplicity
Of pastoral poetry,
With the sweetest tenderness
Of the Elegiac.

On, still on, to the Rotunda, whence there is an exquisite view of the dingle. The rivulet that runs along the bottom is dammed into pools, and one of them is seen through a vista or arcade formed by the branches of the trees. It is a scene to be felt, not described—a music of the eyes, a melody of the heart, whose truth is known only by its sweetness. Short views of forest glades down the glen are diver-

sified by the straggling trees that hang upon the declivities. A Cedar of Lebanon in the dell measured 18 feet 3 inches in girth at 3 feet from the ground. It appeared worthy indeed to be the emblem of the majesty of Israel. An Oak larger than its companions measured 15 feet 7 inches in circumference, and the bole to the branches was 20 feet high.

The next object I came to was a pedestal, with the following brief notice—

"ALEXANDER POPE, 1744."

The next was the crowning-point of all—the Ruined Castle, a masterly deception, standing on the highest ground in the Park, and commanding an extensive prospect on to the Malvern Hills, the Welsh mountains, Woodbury, and splendid home views of the diversified scenery of the park, the dingle, and the pools. Then home by a tablet dedicated to Milton, with the following lines from his "Paradise Lost:"

"These are thy glorious works, Parent of Good!
Almighty! Thine this universal frame,
Thus wondrous fair. Thyself how wondrous then,
Unpeakable! who first above these heavens
To us invisible, or dimly seen
In these thy lowest works; yet these declare
Thy goodness beyond thought, and power divine."

Geologists tell us that the body of the earth was once in a state of fusion—that is, it was once all in a melted state, glowing, burning, flaming, and that it gradually cooled until it became covered with a hardened surface. This park in the convulsions of Nature seems to have been tossed up into all sorts of forms, and is now clothed with trees, some appearing in full view, others half concealed behind the rising banks, and others with their rounded heads appearing above the summit of one range as if they were clumps of shrubs seated on the sloping banks of the more distant hills. Such extent of ground, such variety in the disposition of it, objects so interesting in themselves and ennobled by their situations, each contrasted to each, every one distinct, and all happily united—the parts so beautiful of a whole so great compose altogether a landscape of some magnificence and of great beauty.

I have seen many landscape paintings where the trees have been grouped in the most picturesque manner, and where the soft green glades have been displayed in a very delightful style to give variety, light, and shade, and where the tone of colouring and all the other accompaniments have been employed by the landscape painter to realise the best creations of the imagination; but I have rarely seen any landscape to compare with the scenes that are produced in this place. These scenes are produced by groups of trees, the Oak, Beech, and Chestnut predominating, disposed, not in the random manner recommended by some landscape gardeners to produce some effect, and to be left as a haphazard attempt at a composition most incongruous, but in a method upon which the mind was employed to picture the future effect from the original arrangement—to see them gradually developing their forms and features with their growth, until they ultimately attain a beautiful landscape, the object pre-conceived from the beginning.

Mr. Loudon, in his "Encyclopædia of Gardening," describes Hagley, "A square house with raised pavilions at the angles, in a park long celebrated for the beautiful undulations of its surface, the fine scattered groves and thickets of Beech and other trees. As a seat, however, it is deficient in having no pleasure ground or flower-garden scenery near the house. This must naturally lessen the comforts of its possessors in the winter months, who must cross the open park before they can get at gravel paths of any kind." A person who had never seen the place would naturally conclude from this description that the house was isolated in an open exposed situation. It is true there is no pleasure-ground or flower-garden scenery around the house, but it is naturally sheltered by rising grounds, and the walk of about 50 yards leads to the shrubbery and pleasure grounds. To my taste it is better as it is. You go forth to enjoy the shade and shelter of a short walk through flowers and shrubs, or, if inclination leads you to extend it through woodland scenery in the park, there is the charm of variety to engage your attention; while flower gardens or pleasure grounds seen from the house, being always visible, become monotonous and devoid of interest. The beautiful ground

around the house is varied by gentle swells and graceful slopes; here dipping into easy hollows, and there rising in gradual ascents of moderate height. The varied undulations, and the different shadows and tints of mild colouring thrown across the view by the different inequalities, form of themselves a pleasing picture.

I cannot conclude without returning my grateful acknowledgments to Mr. Mackie, the head gardener, for his hospitality and kindness in accompanying me to all the various scenes in this extensive and beautiful park.—W. KEANE.

ASPARAGUS-BEDS—FRENCH CULTURE.

I do not know if it be permissible to comment on your answers to correspondents, but if so, may I be allowed to make a few remarks on "G. A.'s" answer to "H. N. E." page 479, No. 194.

I cannot tell what the questions may have been, that were put by "H. N. E." but presume them to have been elicited by my short paper on the French method of cultivating this esculent in your Number of the 1st of November; but I will confine myself to the remarks of "G. A." He says—"There is no benefit in the French system, unless you wish to have Asparagus with a long, slender, underground shoot, with no more of it eatable than the green or purple tips." Well, I must not be rude, so will merely say, that it appears to me rather a cool assertion, after my description of that grown by L'Héraut, père et fils, a bundle of thirty-six heads of which weighs 14 lbs. I admit that the shoots are long, very long, 14 inches, but with that weight the reverse of slender, I think.

I saw the plants growing, and although I certainly did not measure them, yet I may venture to say that the stems were 1½ inch in diameter above the ground. Is that called slender? "G. A." then goes on to say, "In what way the uncovering of the roots in winter can benefit the plants we cannot perceive." I beg his pardon, he does perceive it, and very clearly, too, which he proves himself, as he says a little further on, "The beds being covered with soil in spring, it is necessary to take a quantity off in autumn, so as to prevent the crowns rotting, as they are liable to do when in a wet soil, and in order that the roots may be better manured." That is it exactly. I could not put it better myself.

Again, he says, "The earthing-up in spring blanches to the length of 9 inches, with the tips just coloured. Such look very nice, but are tasteless, the underground white part being about as tough as the root of an Elm tree." May I ask "G. A." if he has ever been in France, and did he ever eat French Asparagus? Does he know that hundreds of pounds sterling are taken of Englishmen weekly in the "Halles" of Paris, for this vegetable for the London market?

Does he think that Frenchmen, notably the greatest epicures in the world, that Englishmen who can afford to pay 20s. for a bundle of thirty-six heads of Asparagus, would be likely to eat it, if it were as tasteless and tough as an old Elm tree? I can assert, on the contrary, that it is deliciously tender, and full of flavour, green, purple, and white.

I fear "G. A." is one who thinks nothing can be good out of England. I do not particularly object to that, I rather admire a man of good, obstinate prejudices in favour of his own country, as Dr. Johnson liked a good hater.

I could not, perhaps, discuss scientifically this question with "G. A.", but I see the naked fact staring me in the face—the French produce finer Asparagus than we do. We cannot get over that. Let us try, then, and equal them if we cannot surpass them. L'Héraut tells me we shall never do this last, because we have no worn-out vineyards in this country, and that is the soil especially adapted for the growth of Asparagus.—H. S. WATSON, *The Cottage, Old Charlton.*

[It is quite admissible to comment upon anything that appears in our columns, for we have no object but the eliciting of truth. We have seen Asparagus grown in England as large as that named by our correspondent. A bundle was exhibited any three heads of which weighed a pound. It was, as our correspondent describes the French Asparagus, fully a foot in length; but then if 3 or 4 inches of the French Asparagus are eatable, then is it superior to that we saw exhibited of English growth, for of that not more than from 1 to 2 inches were edible, the rest, as "G. A." describes it,

was "as tough as the root of an Elm tree." Soil, no doubt, has much influence over Asparagus, but climate has more. In a warm climate where its progress is more rapid, the white part during early growth is less woody, as for the same reason it is in forced Asparagus.—EDS.]

PEARS FOR THORN STOCKS.

I SHALL feel obliged if you will inform me what varieties of Pears take best on the Thorn. I have an idea that, double-worked, it will be a very good stock in some soils; but so far as my own experiments go, although the fruit seems to be improved in flavour, the trees are short-lived. If I could find a sort that took kindly and grew vigorously I should feel inclined to propagate it freely.—T. G.

[The Vicar of Winkfield and Louise Bonne of Jersey you will find two varieties that make a vigorous growth on the Hawthorn. That some varieties are not short-lived when grown on that stock we have sufficient evidence, for we know a tree of the Styrian nearly thirty years old which is now perfectly healthy, and bears an abundance of fruit annually. This is a subject we should like to see carried out more fully than it has hitherto been by fruit-growers.]

BIRMINGHAM FRUIT SHOW.

In your last week's impression appeared a well-written paper by Mr. W. Miller, which in my opinion was indeed a word in season. I attended the above Exhibition, and looked carefully through the different classes, and I was quite as much surprised as Mr. Miller seems to have been at the way in which many things were managed. In the first place, the first prize for twelve varieties of kitchen Apples was awarded to Mr. C. J. Perry, one of the Honorary Secretaries. This collection should have been disqualified, not but that it was undoubtedly the finest collection, but it consisted of only eleven varieties, two dishes containing Blenheim Orange—one dish exhibited under the above name, and the other under the name of Blenheim Pippin, which every gardener knows to be one and the same variety.

In the second place, the gentlemen's gardeners who exhibited at this Show are not likely to exhibit again unless under very different conditions; for one well-known fruit-cultivator told me that it was the first and last time he should think of exhibiting on any such terms. If it is foreign fruit that is wished for by the managers of the above Society, why not have a collection limited to such, and also a collection of English-grown fruit for English gardeners to exhibit, and of which they might be justly proud, instead of inviting them to be at the expense of conveying their own productions to and from an exhibition, without the slightest chance of success, against Channel Islands' fruit? It is not to be expected that gentlemen's gardeners with their numerous and never-ending duties, if they even wished so to do, could find time to tear about the country like a commercial traveller to hunt up the finest dishes of different examples they might meet with, much less could they visit the Channel Islands.

In the third place, the twelve first and four second-prize cards placed in front of the Hon. Secretary's winning collections contained the following words:—"First or second prize (as the case might be), to C. J. Perry, Esq.;" but then followed, "Gardener, Thomas Pointon." This last part at least must be a delusion, for what could this Thomas Pointon know about the greater part of his master's winning-dishes of fruit? Nothing more than, perhaps, the unpacking thereof. What care or pains had this gardener bestowed on their production that his name should so figure? How often had he rolled down the tiffany to protect the blossoms in the spring? or later in the season carefully thinned the fruit? or, later still, protected it against and watched for wasps and other pests? There were exhibitors at this Exhibition who had bestowed all due care upon their productions; but how did they stand? Why, by the side of this fine foreign fruit they were many lengths behind. It may be said they were not obliged to exhibit. Certainly not; but why send invitations round, and so get together some good growers with good English productions, to find

themselves cut out altogether by fruit grown in a more genial clime, and purchased, begged, or borrowed purposely for this Exhibition—and by whom? Why by one of the Honorary Secretaries.

The Pears and Apples from Jersey were certainly very fine indeed, but it is out of all reason for them to come into competition with English-grown fruit; and therefore, as I said before, it shows the absolute necessity of distinct classes for all foreign fruits, if any satisfaction is to be given.

Lastly, I agree with Mr. Miller in thinking that a thoroughly healthy horticultural society is much wanted in Birmingham; but at the same time I trust the next schedule of a fruit show that may be issued, will be one that will not only tempt but repay thoroughly good fruit-cultivators to put in an appearance, so that really fine English fruit may meet with its deserts, and not all the principal prizes go to foreign fruit-jobbers.—W. H. TREEN.

WINTERING PLANTS WITHOUT ARTIFICIAL HEAT.

In your Number of December 13th, there is an inquiry from a "YOUNG GARDENER" as to the best method of preserving his bedding plants during the winter in an unheated greenhouse. This is a difficulty that must have forced itself upon the attention of gardeners over and over again, especially of late years when so large a stock of bedding plants is required.

Professor Piazzi Smyth informs us that from careful observations carried on for many years at the Royal Observatory at Edinburgh, it is found that the mean semi-annual variation of heat amounts at the surface of the ground to 50° Fah.; at 3 inches under the surface 30°; at 3 feet 16°; at 6 feet 10°; at 12 feet 5°; at 24 feet 1°.

Thus we see that at a depth of only 6 feet, the mean variation is five times less than at the surface of the ground. I cannot, therefore, help thinking that the knowledge of these facts might lead gardeners to a solution of their difficulty. Let the house intended for the preservation of plants during the winter be sunk 6 or 8 feet below the surface of the ground, and you may do away with flues, and pipes, and charcoal, with their disagreeable accompaniments of coal and smoke and ashes, to say nothing of the expense, and constant attention and anxiety which attend them.

As regards light, the glass roof would be the same as now. For ventilation, air might be admitted to the bottom by means of a pipe, similar to the wind-sails for admitting air to the holds of ships, with two or three ventilators or apertures at the top of the structure; and the necessary drainage could be easily effected.

It also appears to me that the present sloping stages with the plants in pots exposed to the air on all sides, are very unsuitable for preserving them during the winter. Would not horizontal stages be better? the plants being placed in boxes somewhat larger than Mignonette boxes; and two or three of these horizontal stages might be arranged one over the other, thus accommodating a greater number of plants. The lower stage would not have much light, but that is not of vital importance with the present object.

If additional security against frost were required, a baize cloth might be stretched when necessary at the top of the house, from back to front, about 1 foot beneath the glass. I have made the above remarks merely by way of suggestions.

—ISLE OF WIGHT.

LATE MELONS.

I SEE in your report of the Fruit Committee of the Horticultural Society that a Melon was exhibited by Mr. Short, gardener at Clewer Park, Windsor, of excellent quality for so late in the season. I cannot but congratulate Mr. Short on such a decided success. A late Melon cannot be otherwise than a decided acquisition where much fruit is in demand, more especially when it is required to be of good flavour. Some time ago I communicated an article to your pages pointing out the desirability of a good late Melon, as I then considered such possible, and I am glad such results are already accomplished. When gardener at Crom Castle

in Ireland, Mr. Short kindly forwarded me a few seeds of a Melon called "Graham's." I changed my abode before the Melon was ready for table, but I understand from my successor that "Graham's" Melon is a first-rate kind as regards flavour, being the best by far amongst a good many other kinds. Mr. Short appears to possess some really good kinds, which I hope he will enable other cultivators to obtain.—JOHN EDLINGTON, Wrotham Park, Barnet.

PROTECTING BUDS FROM BIRDS.

I WAS much struck the other day while walking round the grounds of my neighbour, Mr. Rivers, with two rows of Plum trees, large pyramids from 12 to 14 feet high, and nearly as many years old, all apparently surrounded by a network of lace, which in the bright sunshine was quite dazzling, owing to the heavy coat of rime on each thread. I found on inquiry that the buds of these Plum trees were in such high favour with the sparrows and bullfinches, that they usually stripped the trees during the winter, not attacking trees of other sorts growing near them, the buds of the sort in question, the Reine Claude de Bayay Plum, being apparently their favourite food. On examining the trees I found the apparent network formed by white worsted carried round the outside shoots of each tree, with a twist round the ends of several twigs to make it hold fast. It thus formed a net with meshes from 1½ to 2 feet in diameter. I was assured that this was an old custom, but a sure preventive to the vexatious depredations of bud-eating birds. I observed, also, on the lawn some large bushes of the May Duke Cherry, the buds of which are such especial favourites with bullfinches, protected by white worsted, and not a bud was touched. The cost and trouble were not heavy, 2½ lbs. of worsted and two boys with a short ladder netted one hundred large Plum trees in two days.—PRUNUS.

WHITE ISCHIA FIG—CANARY AND HONEY PEACHES.

IN reply to "R. F.'s" inquiry (page 439) regarding the White Ischia Fig, I cultivated it many years in a house without heat, but never obtained anything more than a stray specimen of fruit. This was, of course, fruit of the first crop. Upon making inquiries of a Fig amateur who had lived in Italy, I was informed that the White Ischia was equally loth to give a first crop in its native land, so I put my plant into a heated house, and now obtain an abundant second or autumnal crop. Its flavour is so peculiar and so excellent, that I have increased my stock, and tried one tree in the border of the house, but the fruit was no larger than from pots. The compact growth of this variety makes it very desirable where space is scarce.

In page 430 of your Journal Mr. Bréhaut appears to say that a Canary Peach ripened in his orchard-house on the 11th July. Surely, if this is not a misprint, the house must have been heated. The Honey Peach, to which he also refers, is a most singular fruit. In taste it is very sweet; but the shape is so like a swollen almond that it is possible that the Peaches described by the ancient Romans may have been nearly allied to this variety.—S. B.

NEW BOOK.

The Cottager's Garden Guide. Edinburgh: Andrew Elliot. London: Hamilton, Adams & Co.

We believe that it is no secret, and we are sure that it ought not to be, that this excellent little threepenny book was prepared by Mr. Cunningham, a writer to the signet, and landed proprietor in Scotland. He had observed, as all must have observed who have travelled among highland and lowland cottiers, that they, as a rule, neglect gardening. There are many notable exceptions to be met with, but generally the Scotch cottager neglects his garden. This, at the first thought, seems the more surprising, because gardeners are one of the three great exports of Scotland, doctors and black cattle being the other two; but if we inquire we find that the gardeners by profession are not

usually the offspring of Scotland's cottagers, they are, for the most part the sons of a higher class.

Be the reason what it may, the fact is patent that Scotch cottagers neglect gardening, and to rouse them and to guide them from this injurious neglect is the object of the work before us. "They will find," says the introductory note, "by paying a little attention to the subject, that it is quite within their power to obtain either some addition to the comforts of their own firesides, or a little money from the sale of the produce."

"This small publication may also, perhaps, prove useful to parents who desire to give their children a taste for flowers, and to encourage them in the innocent pleasure of rearing their own plants."

"The object has been to give practical information, so that any one may easily find out what to put in his garden, the quantity and price of seeds required, and how common vegetables ought to be cooked."

Such are the writer's praiseworthy, disinterested objects, and without any reserve we say that whoever follows the instructions he gives, will not fail to attain them. Let us add, that although Mr. Cunningham gives the instructions, and is well capable of giving them, yet with the good spirit of one who not only wishes to be of service, but is anxious to adopt the surest mode of conferring the benefit, he has had the pages of his little book revised by some of the ablest gardeners, and other good authorities.

We commend the work to our readers; and those of them who wish to distribute such a guide among cottagers not yet attracted to gardening, or who need more information, may obtain the book at the reduced price of 2s. per dozen.

PRODUCE FROM AN ORCHARD-HOUSE.

SEEING a wish expressed by one of your correspondents, that cultivators of orchard-house trees would furnish a statement of the quantity or size of various fruits under their superintendence, I enclose mine, hoping you may think it likely to prove interesting to your readers.

I have two small houses, one 15½ feet by 12, the other 18 feet by 8½, and in them about eighty trees of various descriptions. The Peaches, Nectarines, and some of the Plums are kept under glass the whole season. The Pears, Apples, and the remainder of the Plums are placed out of doors about the 25th of June, the pots being plunged half their depth in the soil. Size of the pots 12's, 8's, and 6's.

The Peaches and Nectarines were over-cropped, one having forty left on it, when prudence said twenty would have been a good crop, consequently they were rather small, but the flavour was generally good. The Pitmaston Orange Nectarine bore a large crop of excellent flavour and size. As regards Plums, Coe's Golden Drop bore a good crop, flavour delicious; Jefferson, two years in pots, bore forty-six fruit of the usual size; Pond's Seedling, thirty fruit, beautifully coloured, six weighing 13 ozs., or rather more than 2 ozs. each.

APPLES (beautifully coloured).—Brandy Apple, 7½ inches circumference; Mela Carla, 11 inches; Melon Apple, 12½ inches; Reinette du Canada, 13½ inches.

PEARS.—Beurré d'Esperen, 7½ inches by 7½; Beurré d'Arenberg, 9 inches by 8; Joséphine de Malines, 8½ inches; by 8½; Winter Nelis, 9¾ inches by 10; Beurré Diel, 7¾ inches by 11. The flavour of those which have ripened has been delicious.—W. H. T., *Sawbridgeworth, Herts.*

P.S.—Mr. Rivers saw the above Apples and Pears growing, and pronounced them first-class fruit.

CULTURE OF LEOPARD'S BANE.

OWING to the machinery being out of repair at a woollen mill, a number of young women were for a time thrown out of employment. Having nothing to do they took a ramble into the country. One of them bent on gathering wild flowers rambled into a wood, where, in a boggy place near a stream, she gathered a handful of the flowers of *Doronicum pardalianches* (Leopard's Bane). Pleased with them she showed them to her partners, who on their return gathered handfuls of the flowers. They were shown to the operatives at the mill, the flowers were new to them; having

cottage gardens at home, they inquired where the wild plants grew, and went and gathered roots which they planted at home. They grew, and next season flowered abundantly. The cottagers were pleased with the flowers, and distributed roots among their neighbours and friends. The Leopard's Bane is now a common plant, and is one of the cottager's favourites. It is easily propagated by dividing the roots, which are composed of several knobs connected by long fibres. The best spot to grow it is a damp soil, there it will flower for a long time. The flowers come at the end of the branches, are overtopped by succeeding ones, and are of a bright yellow colour.

With us it is a rare wild plant, and if the herbalists collect the leaves as eagerly as they have done in the last season, it will not be long before it is exterminated.—*RUSTIC ROBIN.*

THE MATURING OF FRUITS.

I SHALL be glad of some information relative to the maturing of fruits, particularly the later sorts of Pears. I think there is much yet to be learnt of their proper treatment, which treatment, perhaps, ought in some measure to vary with each sort, if this were practicable.

Take, for instance, the Beurré de Capiaumont. Mr. Rivers classes it among the stewing Pears, whereas with me if not allowed to hang too long on the tree, and so soon as gathered put into a room where the temperature never or seldom falls below 60° Fahr., it is in about a fortnight or three weeks one mass of juice, and of very high flavour, but, unfortunately, it does not keep after this stage is reached more than a day or two.

So with the Marie Louise, the Beurré de Rance, and some others, although I prolong their season by keeping them in a cold room, I never develop their flavour as I do when kept warmer. In fact, in the case of Beurré de Capiaumont, if I keep it cool a fortnight after gathering it never becomes melting.—T. G.

PROFITS OF A VINYERY.

HAVING noticed discussions on orchard-houses in your Journal for some time, I thought an account of a house under my care might interest some of your readers.

When I came to this place (Manor House, Ashton-on-Mersey), an orchard-house was about to be erected. It is 60 feet by 20, but 6 feet are taken off for the boiler and potting-shed. Air is given at the sides and top, in a similar manner to the one at Great Marlow. It has a double row of four-inch piping, flow and return, along each side and one end; but as the lady I have the honour to serve wanted flowers, the internal arrangements were altered. A partition was put across the centre, making each part 27 feet long. The front was filled with stands suitable for plants, the other portion with bedding plants. Ten Vines were planted on each side; they were planted inside, and the roots allowed to run out. In the hot summer of 1859 they made excellent growth, and in 1860 they were allowed to carry two bunches each. In 1861 they carried six bunches each. In 1862 we began selling the Grapes, realising £40, and in 1863 we made £51 13s. 6d. We have just done cutting Grapes, and I find we have made this year £61 19s. 10d. If the account from Great Marlow be a fair calculation, I think Vines would be most profitable, besides the advantage of growing plants underneath them.—S. RYDER.

[Our correspondent calls the structure an orchard-house, but it is a heated vinery. He does not say when he begins forcing, nor how early the Grapes were ripe.—EDS.]

RETINOSPORA OBTUSA.

I OBTAINED a few small plants of this Japan tree about a year ago, and being uncertain whether they would prove perfectly hardy or not I planted them in a cold pit. In the severe weather of last January I stuck a few laurel boughs amongst them and over them, and they escaped without the least injury. In fact, I think they would not have suffered if they had been perfectly exposed. It is not, however, to their hardiness but to another circumstance that I wish to direct attention. Since the summer growth has perfected

itself, or even before then, the plants have become of a pretty golden yellow, quite as much so as *Thuja aurea* in its best state in spring or early summer, and the appearance is certainly more handsome than the Golden Yew is at any time. I now ask if this is the usual character of the species, and if not, whether this feature is likely to become permanent? If so, the tree will be a great acquisition to our shrubberies and elsewhere.

I may add, that *Retinospora pisifera* is growing by the side of the plant above mentioned, but shows no symptoms of turning yellow; and one plant of *R. obtusa* also retains its green colour. The soil they are growing in is a sandy one, such as is occasionally used for cuttings, and plants only partially rooted. I do not perceive any disposition on the part of other plants in the pit to change colour, there being some of *Cupressus*, *Juniperus*, *Wellingtonia*, &c., and to the best of my memory the plants of *Retinospora* here alluded to showed no symptoms of turning yellow at the time they were planted, which was at the end of October. If others of your readers have plants of *Retinosporas* that have changed in like manner, they may, perhaps, be able to throw some light on the matter.—J. ROBSON.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE Entomological Society's meeting for December was held on the 5th inst., the President, F. Pascoe, Esq., F.L.S., being in the chair. A numerous collection of entomological publications presented to or purchased by the Society since the last meeting were laid on the table, including Dr. Haagen's recently published memoirs on the invertebrated animals of Prussia and on the Odonata of the Holy Land; MM. Saussure & Sichel's new work on the Scoliidae, Dr. Candeze on new Elateridae, the Baron Lelys Longchamps on Agrionides, &c.

Mr. Jenner Weir exhibited a series of carefully prepared microscopical slides containing specimens of the spiral tongues of numerous species of British Butterflies, and exhibiting great variation in the striation of these organs, and in the form, arrangement, and number of the minute papillæ at their extremity. Even in closely allied species, as *Vanessa C. album* and *Io*, these variations were found to be very strong.

Mr. Frederick Bond exhibited a photograph of a strange variety of the common Magpie Moth, *Abraxas grossulariata*, the fore wings of which were nearly suffused with black markings; also a drawing of the larva of *Acronycta strigosa*.

The Rev. Hamlet Clark exhibited a collection of minute Beetles collected in Egypt by the Rev. P. Cambridge, as well as a number of Ants of different species collected in Syria by Mr. Lowne.

Mr. F. Smith exhibited, on the part of Mr. Stone of Bright-hampton, a remarkable Wasps' nest, variegated in the colours of its outer covering, having been formed jointly by two distinct colonies of *Vespa vulgaris* and *V. germanica*, one of which was placed in a box in a bedroom window, and the other in the window immediately beneath it; and Mr. Stone observed that when any individual of the upper colony flew low on returning home, it mistook the nest and entered the lower one instead of its own, and thus a different colour was caused from the two species differing in the nature of the wood of which the covering was made, one species selecting hard sound wood, and the other such as was decayed. Mr. Stone also exhibited the larvae of *Ripiphorus*, parasitic in Wasps' nests, one of which still remained attached to the body of its victim, the grub of the Wasp.

Mr. W. F. Evans exhibited a number of specimens of a small green species of Cockchafer (*Pyronota aestiva*), from New Zealand wool, in some bales of which thousands of specimens could have been procured. It was supposed that in flying about the sheep they had become entangled in the fleece.

The President exhibited some small globular nests of a species of Spider from South Australia, collected by Mr. Audubon, closely resembling the seeds of *Lophospermum*, the Tea plant of Australia, whilst the Spiders themselves resembled small lumps of birds' excrements; and as they kept watch near the nests, insects on which they fed were easily deceived.

Mr. Stevens exhibited a number of insects forwarded from

tropical Western Africa, Fernand-vaz River, by M. Du Chaillu. He also read a letter from the same gentleman, stating that he had dispatched a living Gorilla to Europe; but it had unfortunately been killed in the boat which was conveying it to the vessel, in which it got loose. Mr. Stevens also exhibited some specimens of the rare African Beetle *Cheirobasia Barkei*, one of the males of which was remarkable as wanting the brush of hairs on the fore tarsi, which is one of the distinguishing characters of the male of this species. These insects had been sent by Mr. Layard from South Africa.

Mr. Hewitson sent a monograph of the genus *Ypthemia* belonging to the Satyroid Butterflies, together with descriptions and figures of two new allied genera.

Mr. Kirby read some notes on the synonymy of various British species of Butterflies, insisting that their names required changing by the rule of priority in favour of other names bestowed on them by previous writers.

Mr. F. Moore exhibited an extensive series of silk and silk-producing insects; and communicated the completion of Captain Hutton's remarkable Memoir on the reversion and restoration of the Silkworm in India, containing descriptions and figures of the caterpillars of various kinds of Silkworms cultivated in that country.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

ACMENA FLORIBUNDA (Copious-flowered Acmena).—*Nat. ord.*, Myrtaceæ. *Linn.*, *Icosandria Monogynia*. Native of New South Wales. Flowers inconspicuous, but its clusters of bright purple berries are very showy. Tree 20 feet high, like a gigantic large-leaved Myrtle, would be highly ornamental in the conservatory.—(*Botanical Mag.*, t. 5480.)

ARAUJA ANGUSTIFOLIA (Narrow-leaved Arauja).—*Nat. ord.*, Asclepiadaceæ. *Linn.*, *Gynandria Pentandria*. Native of the forests of Uruguay. Stove climber with yellowish white, not conspicuous flowers.—(*Ibid.*, t. 5481.)

DENDROBIUM JAPONICUM (Japanese Dendrobium).—*Nat. ord.*, Orchidaceæ. *Linn.*, *Gynandria Monandria*. Common in Japan. Flowers white, not showy.—(*Ibid.*, t. 5482.)

BARTONIA NUDA (Naked (Bractless) Bartonia).—*Nat. ord.*, Loasaceæ. *Linn.*, *Icosandria Monogynia*. Native of Missouri, introduced by Mr. Thompson, of Ipswich. Flowers yellow, but, as Mr. Thompson fairly points out, "It cannot be looked upon as a hardy ornamental plant, the flowering taking place only late in the evening, and at a season (October), when it is too late for the ripening of the seeds."—(*Ibid.*, t. 5483.)

VERONICA HULKEANA (Hulke's New Zealand Speedwell).—*Nat. ord.*, Scrophulariaceæ. *Linn.*, *Diandria Monogynia*. "Quite a new form of *Veronica*." Native of the mountains in the middle island of New Zealand. In a cool greenhouse it flowered in May, but from growing at 2000 feet elevation in its native island, it may be expected to be hardy here. Flowers lilac, and in a thyrsus like those of the common Lilac shrub.—(*Ibid.*, t. 5484.)

EPISTEPIUM WILLIAMSII (Mr. Williams's Epistephium).—*Nat. ord.*, Orchidaceæ. *Linn.*, *Gynandria Monogynia*. Native of tropical South America. Flowers of a fine, light, red-purple colour.—(*Ibid.*, t. 5485.)

SAXIFRAGA FOETIDA.—One of the numerous variegated plants of Japan. The leaves are of the dark green usual in the genus, but variously blotched on the upper surface with white and pink.—(*Floral Mag.*, pl. 221.)

GLADIOLUS, ELEANOR NORMAN.—Raised by Mr. Standish, Royal Nursery, Ascot. Flowers white tinged with pink, and flaked with dark pink stripes.—(*Ibid.*, pl. 222.)

DISA GRANDIFLORA var. *SUPERBA*.—We noticed this recently in Messrs. Warner and Williams's "Orchidaceous Plants."—(*Ibid.*, pl. 223.)

PENTSTEMONS.—*Princess of Wales*, white, with lips broadly bordered with pink. *Attraction*, white, tinged with pink. Both raised by Mr. Salter, Versailles Nursery, Hammer-smith.—(*Ibid.*, pl. 224.)

CLEMATIS RUBEO-VIOLEACEA.—Raised by Mr. G. Jackman, Woking, by crossing *C. lanuginosa* with *C. viticella*. It is quite hardy, and, as its name indicates, the colour of the flowers is reddish purple.—(*Florist and Pomologist*, iii., 265.)

FOUNTAINS AND ROCKWORK AT DINORBEN HOUSE.

THESE, which we noticed at page 436, were executed in terra cotta by Mr. James Pulham, Broxbourne, Herts, in the year 1859.

The fountain called the Hebe is represented in our engraving; it is 20 feet high, and is in the centre of a four-lobed basin 42 feet in its widest diameter. The whole cost £280. The material of which it is formed is terra cotta of the colour of Caen stone, and is said to be very durable, which might be expected from its being burned until semi-vitrified. The water of the fountain, from the jug held by Hebe, flows into a cup held in her other hand; but it also rises from the nostrils of four dolphins, and from the upper basin falls into the lower one. Round the latter is an outer basin 3 feet wide, for plants. A similar Hebe fountain has been sent to Bombay by Mr. Pulham, to be fixed in the grounds of Sir Jameset Jeebhoy.

It is ornamental, even when the water is not flowing, which cannot be said of all fountains.

TRENTHAM BLACK GRAPE.

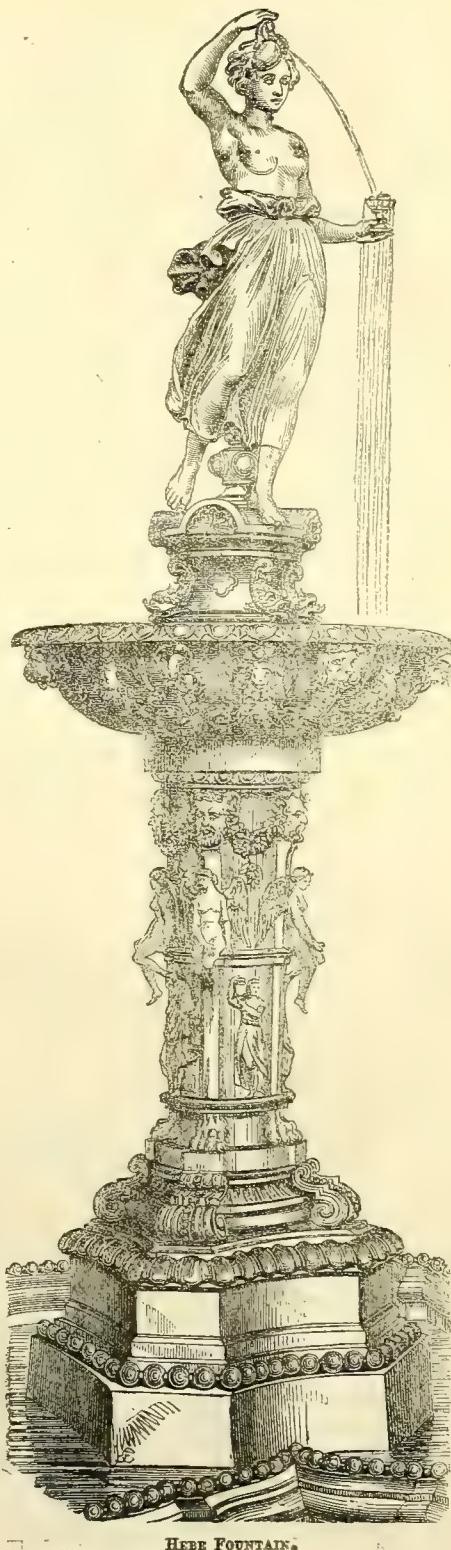

RESPONDING to your request in the JOURNAL OF HORTICULTURE at page 410, I beg to state that I obtained a plant of the Trentham Black Grape direct from Mr. Fleming as soon as it was distributed, which I think was in the year 1858. I was induced to get it through the recommendation of a friend of mine (now deceased) who had just visited Trentham, and had there seen it fruiting remarkably freely in pots. So fine were the bunches, and such the number produced on comparatively small Vines, that he thought it would prove the most useful and prolific Grape for pot culture that he had ever seen. Being myself fond of the cultivation of Vines in pots, I immediately set about propagating it from all the laterals I could command, and by the autumn I succeeded in obtaining several strong canes fit for fruiting in the ensuing season. These were duly started the following spring, and I naturally anticipated a fine crop of Grapes, but to my surprise such was not the case; for, instead of bunches, I had claspers in almost every case, the isolated bunch or two produced being also of a very inferior character com-

pared with what I had been led to expect. I, however, resolved to try it another year, and at the same time to send an eye or two to a friend of mine, who is a first-class grower of pot Grapes, to see if he would meet with any more certain success than I had done. However, in the following spring I received a note to the effect that

Trentham Black had proved a failure with him, as well as myself, and that he considered it a shy bearer, and consequently an unsuitable variety for pot culture.

So much for its unsuitability for pot culture. I will now endeavour to state its adaptability for viney cultivation. The original Vine was planted out in the June of the same year in which we received it into an inside border of a cool viney, where the Grapes are generally ripe by the first week in September. It was allowed to grow vigorously for a couple of years, and the third year we hoped to have taken a few bunches from it; but strange to say, although an unusually strong well-ripened cane, it showed but two or three bunches, and these were small and puny. The next year, however, the result was gratifying, and for the last two or three years it has borne magnificent bunches, with a profuse bloom of an intense purplish black colour, and a most delicious flavour, being more juicy and rich than the Black Hamburgs in the same house, and it has in every way proved itself a most desirable (and with my employer a favourite) variety. I have observed that it retains its leaves in a healthy green state much longer than any other variety growing in the same house, which would naturally lead one to suppose that the bunches would hang much longer than on the other varieties having less vitality. This, however, is not the case with us, for we find the berries invariably mould and decay earlier than the Black Hamburgs in the same structure. This circumstance arises probably from the berries containing a larger quantity of those juices which tend to hasten decay.

From the above facts I am led to infer that this variety is not a desirable one for pot cultivation; but when grown in a cool or warm viney, and closely pruned, it cannot fail to give universal satisfaction. For an orchard-house, regulated as Mr. Pearson advises or teaches in his very sensibly written book on orchard-houses, I have not the slightest hesitation in recommending it as a suitable variety.—HENRY MUNBO, Cleveland, Lyme Regis, Dorset.

HEBE FOUNTAIN.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE weather must now decide the operations to be performed in the kitchen garden. If frosty all manures ought to be wheeled to where they are wanted. If the Asparagus-beds are not soiled up for the winter, no time should be lost in getting it done. In open weather trench or dig all vacant spaces; trenching is a prospective operation, therefore the bottom ought to be manured well, as by that process land will remain in heart three or four years, and after that time a second trenching will bring up the soil from beneath. *Brussels Sprouts*, when gathering do not cut out the crowns until spring. Some do so in the hope of inducing them to throw out more sprouts, but we think it injurious at this season, as it admits moisture, which in the event of severe frost, proves fatal to the whole stem. *Cauliflowers*, stir the surface of the soil amongst the plants under hand-lights, and sprinkle some charcoal dust or wood ashes amongst them; it will sweeten the surface of the soil, and prevent the green growth over it, which stagnant air is apt to produce. For land that has been long cropped with vegetables, a dressing of fresh loam would in many cases be preferable to manure, and where this is wanted, and can be obtained, it should be at hand, in order that advantage may be taken of frosty days for wheeling it upon the ground. Where fresh soil cannot be obtained, charred vegetable refuse, such as prunings of shrubberies, edgings of walks, and many things which turn up in course of the season, may be cheaply made to form an excellent manure.

FRUIT GARDEN.

Figs against walls will require some protecting material placed over them in the midland and northern counties. When the frost sets in lay a coat of manure—say 3 inches thick around the Gooseberry and Currant bushes. Continue to prune and nail wall trees; however judicious the system of summer management, many small bits will require removing before nailing, if the trees are to be kept handsome. We are also alive to the great importance of having a just equilibrium betwixt roots and branches, and in rich garden soil this can only be attained by lifting the trees every two or three years or by root-pruning.

FLOWER GARDEN.

Many persons object strongly to planting shrubs or trees in winter, believing that the roots if hurt at this season are liable to rot, and certainly early in autumn is a much preferable season; but with favourable weather we would not delay such work a single day, and if the soil is properly prepared by draining, &c., where necessary, as should always be done before planting, there will probably be fewer failures from planting now than if the work were delayed till March. But where the garden is of a clayey nature, and in an unkind state at present, it will be better to defer planting until spring. Where Rhododendrons are grown in masses, and exhibit any indications of having exhausted the soil, a top-dressing of rotten cowdung 3 inches deep, and extending as far as the roots, should be applied at once. This will strengthen the plants for flowering, prevent rapid evaporation in summer, and keep the ground cool and moist, which is essential to the well-being of this handsome tribe of plants.

GREENHOUSE AND CONSERVATORY.

The changeable weather which we are now experiencing will render it necessary to carefully attend to specimen hardwooded plants which have to be wintered in these houses. Many of these are impatient of heat and a confined atmosphere. Use no more artificial warmth, therefore, than is absolutely necessary, and endeavour to counteract its drying effects, either by means of evaporating-pans, or by sprinkling the paths or borders, &c., in order to prevent anything like a dry parched state of the atmosphere.

STOVE.

If there is any prospect of a scarcity of plants in flower next spring, a portion of the Gloxinias and Achimenes which have been the longest at rest may be started at once, as also a few Clerodendrons. The latter should be cut back to the lowest eyes so as to secure bushy specimens, with the pots covered with foliage, and when the plants have fairly

started into growth the balls should be reduced sufficiently to allow of giving a good shift in fresh soil without increasing the size of the pots. A few of the Allamandas may also be pruned and placed in heat, provided the wood is well ripened. A plant or two of Echites splendens and Dipladenia crassimoda may also be started. Let Ixoras and all other hardwooded plants that have made sufficient growth be kept rather dry at the roots in order to check their growth, and induce a tendency to form bloom-buds, but do not let the soil in the pots become so dry as to affect the foliage.

FORCING-PIT.

This structure will now be kept in full activity to supply the various calls for plants in bloom, which at this season of the year are more or less in demand in most establishments. Care should be taken before plants are moved to sitting-rooms to gradually harden them for a day or two, either by placing them in the conservatory or an intermediate house. Dutch bulbs should be largely used for present forcing. Do not forget to introduce a good batch of Roses, choosing the most promising plants of Teas, Bourbons, and Hybrid Perpetuals, which are the best kinds for winter flowering. Next to Camellias, Azaleas are, perhaps, the most showy plants that can be had in bloom at this season, and where there is a good stock of these to draw from, some of the most forward plants of the common varieties should be placed in heat at once, moistening them overhead two or three times a-day; but unless the plants have set their flower-buds early in the season, they can hardly be expected to flower so freely or finely as under more natural circumstances in the spring.

PITS AND FRAMES.

The inmates of these structures will require but little water for some time, and the little that may be necessary should be given early in the morning of a fine day, when air can be given to dry up the atmosphere before night. Also, guard against the ill effects of damp by giving air whenever it can be done without risk, but do not expose the stock to cold north, or north-easterly winds, which seldom fail to turn the foliage brown and rusty.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The frost came as was anticipated, 5 10, 15, and more degrees, but with an inch of snow that protected things very much, which was a great advantage after the warm muggy weather had kept plants growing without enough of sun to consolidate that growth. An inch of snow is a matter of importance in such cases. We can offer no better protector. Every flake as it falls on another flake shuts in so much air, and that air so shut in becomes a nonconductor.

Our chief care as to vegetables was confined to Cauliflower, Celery, and Lettuces. The Celery we banked up with stubble, placing a little all over the ridge of the bed, between the plants and over the plants; all the rest will now remain for the season, except what is over the plants, which will be removed that the tops may have sun and air, and may with a few branches of spruce and other evergreens be replaced on a frosty night; and the current of wind and the slight freezing would seem to say we shall not be long without it. These changeable days, ranging so soon from 40° to 26° or lower, render much more care and attention necessary. The Cauliflower under hand-lights was covered over with litter after the soil inside was crusted, and the leaves hard. We thought we were in for a fortnight's frost, or we would not have waited so long. We knew that the frost allowed would do no harm, and after a slight freezing, the plants being in a state of rest, we knew they would take no harm if shut up for a fortnight, a month, or even two months. We once had Cauliflowers shut up thus for ten weeks, and we never had earlier or better Cauliflower. The temperature for all that time must have been from 28° to 32° under the covering. Had it been from 40° to 45° we should have expected to have seen a sickly blanched vegetation. As it was, the covering remained on for twenty-four hours after the thaw set in, and the Cauliflowers being

thawed gradually looked as well as if they had been shut up for one night only. They were just as fresh as a lawn would be that had fallen to a temperature of about 31° before it was covered by a foot of snow for six weeks. As soon as the snow went the lawn looked more healthy and green than it did before the snow came. Cauliflowers and Lettuces for use were protected before they were much, if at all, frosted. In their case the less they are touched the better, and they should not be long covered up continuously unless the temperature is very low, close or freezing.

As to the protecting materials to be used in a hurry, mats are as good as any, but then a single or a double mat is of little use in a severe frost, in a cold pit. A little rough hay is a grand thing for protection, as it lays open, and can also be pressed a little close. Straw is also good, and the less broken it is the better if you can cover with something closer at the surface. Rough stubble is also a good protection for many things, and chiefly because it is open, and allows the air to penetrate and circulate. We protected a lot of glass in a cold pit with it alone the first cold night, and our superintendent of protecting told us he thought it was of little use for a severe frost. That depends entirely on how it is treated. Of itself it would not be sufficient to keep out our most severe frost without very frequent turning, as its very looseness and roughness would allow lines of radiation to reach from the glass to the sky, and thus the frost would enter. But supposing that 6 inches of this loose rough stubble were placed over the glass, and 2 or 3 inches of tree leaves, as we used, or half as much of soft rough hay were placed over the stubble, it would require a very severe frost to penetrate beneath the glass. The very openness of the stubble, a drawback if used alone, became a great advantage when joined with the closer material at the surface. Not only would every straw of the rough stubble serve to prevent radiation, but the closeish material at the surface would make the whole body of stubble beneath a non-conductor. We were not over-well provided with protecting material; but though we had a great number of tender plants in cold and earth pits, the stubble, branches, &c., and some 1 or 2 inches of tree leaves on the top of everything made all quite safe, so that we have not lost a plant.

Those who would take a lesson in protecting should, in a severe frost, examine the state of the ground under long grass, moss, or even a slight covering of tree leaves. We have often been surprised to find how thoroughly Nature accomplishes her objects with the slightest materials. Hints from our pastures and woodlands are often as valuable as hints from books. We have had several letters, in spite of the standing protest of our conductors, about our old friend who took all his bedclothing to save his Apricots and Peaches. It is often important to know what to do in an emergency, and therefore we will mention how another friend, now gone, saved thousands of pots of Mignonette, when almost every neighbour lost them, though we have alluded to the matter previously. The frost came so suddenly that much litter for protection had not been procured. A mat was put over the glass, and a thin covering of litter over it. The frost was so severe as soon to penetrate beyond the mat; but its intensity was rendered harmless by a constant shaking and turning of the litter over the mat. Our old friend and his man Friday worked as hard as they could, one at the front and another at the back of the frames and pits, in turning this litter the whole night, beginning at one end, again, as soon as they reached the other. Every time the litter was shaken and turned it presented a fresh surface to the action of radiation and conduction, and Mr. Frost had to begin his work afresh. We have saved many plants by having the surface of the covering broken before daylight, as just before the dawn is generally the time when the frost is most intense. We have had several private complaints that we did not tell how to save the plants from the coming frost, and we suppose it will be best to plead guilty of not knowing the future; but sure we are that all amateurs will receive a helping hand from their neighbours, and, if wise, they will use the experience of being caught napping as a good reason why they will never be found so unprepared again.

Fruit garden very much the same as in previous weeks.

Looked over Grapes. Gave enough of heat to keep the frost from them, more especially as the most of the foliage was removed. Looked after Strawberries, examined fruit stores, and washed and cleaned second viney, much as was stated as respects the first.

Vines.—We have put in a few eyes, in case we may want them. Those who intend forcing Vines in pots should commence as soon as this sees printer's ink. Young plants are best for this purpose, supposing that a good crop is taken from each plant, and the plants are then thrown away. When the plants are kept on from year to year, a very moderate crop must be taken yearly. We have had from eight to sixteen and twenty good bunches from plants fifteen, sixteen, and seventeen months from the bud-cutting. To expect future crops from such plants would be useless. On the whole, where means are at command, and a fine show a feature, we prefer taking only one crop from the plants. For this purpose the single buds, with three-quarters of an inch at each end of the bud, should be inserted singly in the smallest pots by the first week in January, be placed in a moderate hotbed for a fortnight, and then in a nice sweet hotbed with a temperature of 85° bottom heat, and 60° or 70° top heat. Here the little pots will soon be filled with roots before the bud has made much top growth, and should then be shifted into a larger—say a four-inch pot, using warmed soil, and never allowing the least check to the plants. This plant must be followed, shifting as soon as needed, and giving bottom heat until the plants are in pots from 12 or 18 inches in diameter. These well ripened and placed out of doors in the autumn for a month or six weeks, will be in good order to start in November and December. The general routine has already several times been given. When pots are intended to bear continuously, about four bunches should be the medium. It is best to take a good crop, bring on fresh plants, and throw away the old ones.

Ice.—We went round and looked at the usual pools for supply, and, though there was but little water in the most of them to freeze, we had everything ready to take that little on the following day; but the thaw at night came more suddenly than the frost, and, instead of being helped by rolling snow, the snow had all disappeared before the morning. What ice we could have secured was very hollow, but still it would have been ice; and if we had not still a pretty good supply we certainly should have taken the first chance to obtain a little, even if we had put it in an ice-heap for present use. Most likely we will yet have a more continuous frost ere long; but, as the weather may be uncertain, it will be well not to lose another chance.

We find, on inquiry, that some of our confectioners in neighbouring towns procure the ice they want from London in summer, as the demand for ices, and cooled drinks, is growing even in our out-of-the-way places; and they consider that as yet this mode suits them better than having an ice-heap of their own, though they complain sadly of the necessary expense for carriage, &c., making sad work of what otherwise would be their profits. A larger demand for iced articles would, no doubt, lead to a more general supply. Many large hotels in the country thus obtain their ice from London, or the nearest seaport, and the blocks from Wenham Lake are most valued. In the case of some large hotels this practice is followed even after going to the expense of forming ice-houses, in which the ice will not keep; so that, simple though the matter seems to be, there must be some of the simplicities overlooked, where such failures take place. We have proved over and over again that snow, rolled into large heaps, and well consolidated in the ice-house or heap, is only a little inferior to ice for keeping. If too fluffy to beat well, a little water will remedy that defect. It is best rolled when soft. It is no use trying it when the surface is hard and frost-crusted; and collecting it without rolling it into huge balls is but poor work.—R. F.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—*Sutton's Amateur's Guide and Spring Catalogue for 1865.*
James Veitch, Royal Exotic Nursery, King's Road, Chelsea.—*Catalogue of Garden and Flower Seeds for 1865.*

COVENT GARDEN MARKET.—DECEMBER 24.

Supplies are good and the demand fair, but not very brisk. Pines and Grapes are fully sufficient for the demand; Apples abundant; but good dessert Pears not over-plentiful. Notwithstanding the severe frost of the 18th inst., and general coldness of the weather, the supply of out-door vegetables continues good. The first consignment of Cornish Broccoli has just arrived, and the heads though small are of very good quality. As usual at this season, the market is crowded with carts and waggoners from the country bringing Christmas trees, evergreens, and Mistletoe, for which, notwithstanding the large quantities which have been already disposed of, there is still a ready sale.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

HEATING BY GAS.—In answer to the inquiry made by "G. P. S." I saw a very simple apparatus which appeared to answer the purpose for which it was intended in a small greenhouse belonging to a Mr. G. West, a retired ironmonger, whose invention it is. It is very simple, and consequently inexpensive; but whether the warmth generated would be sufficient for a large house I am unable to say. Mr. West lives on Bexley Heath, Kent, not far from Woolwich, and I am sure he will readily explain his method of heating, and, if required, would erect the apparatus.—G. A. LANDDALE.

CHARCOAL FOR VINES (*A Subscriber*).—We do not know the translation from the German you mention. If we wished to apply charcoal to the roots of Vines we should remove the earth down to the roots nearest the surface, and sprinkle some charcoal broken into small pieces over them. It might be done now.

BUNSEN'S BURNER (*W. Dickson*).—We do not know the maker, but we are told that the burner is well known to and supplied by the gas-fitters.

TAN FOR CLAYEY SOIL (*J. Hurst*).—Decayed tan will be a good and enduring manure for your garden; but, as it is infested with slugs, we would pare off and burn 6 inches in depth of the surface before applying the tan.

MARSH-GARDENING (*R. F. F.*).—We know of no other work on the subject besides that you mention.

FRENCH PELARGONIUMS (*K. D. J. M., Jersey*).—The best houses in Paris for Pelargoniums are Thibaut et Keteler, Rue de Charonne, and Rougier-Chauvière, Rue de la Roquette.

PROTECTING BLOSSOM (*R. S.*).—Your thin canvas will do very well, but we would bring it within a foot of the ground, and only cover that space in severe nights. It would be well to have a two-feet opening every 12 feet, at the top of the wall, to open on sunny days. Your cloth will be more serviceable, if strained, for keeping the blossom dry, than for keeping out much frost.

DOUBLE-GLAZING (*M. R.*).—The distance between the two tiers of glass need not be more than the eighth of an inch. As you are using Hartley's rough plate glass, two tiers of that would exclude the light too much. The inner tier had better be of clear glass.

ASPHALT PATH (*Tyro*).—Take two parts of very dry lime rubbish, and one part coal ashes, also very dry, and both sifted fine. In a dry place, on a dry day, mix them, and leave a hole in the middle of the heap, as brick-layers do when making mortar. Into this pour boiling-hot coal tar; mix, and, when as stiff as mortar, put it 3 inches thick where the walk is to be. The ground should be dry and beaten smooth. Sprinkle over it coarse sand; when cold pass a light roller over it, and in a few days the walk will be solid and waterproof.

FUCHSIA—*CORSEA SCANDENS (Ruby)*.—We do not recognise the Fuchsia by the flower and leaves sent. The flower is that of *F. fulgens*, with the leaves of a reflexed-sepaled kind, as Banks' Glory. As a flower, judged by the standard of the florist, it is valueless; but as a plant for greenhouse decoration, we should think it very ornamental. When it commences to grow thin out the suckers, leaving one only if you wish a plant with one stem, or two or three of the strongest, taking the others away. This will cause the sap to flow more freely into the shoots left, and they will be stronger in consequence, and the plant will bloom more freely. *Cobea scandens* is not hardy so far as we know in any part of Ireland, except in very mild situations, and against walls when protected from frost by a covering of mats or straw. *Lomaria L'Herminieri*, *Nephrodium molle corymbiferum*, *Nothochilus lendigeri* or elegans, *Lastrea glabella*, *Pteris argyræa*, and *Adiantum cuneatum*. *Anemidictyon phyllitoides* requires a cool stove to grow it well, though it will do well in a viney; but what is a viney but a stove in summer? In a greenhouse, especially if cool and airy, it does no good. We are quite certain the plant sent for us to name was *Polypodium cambricum*. We have plants of it from its native home with the fructification plentiful. The person alluded to, we are quite sure, only stated his own experience, and had only come across barren forms of the species.

CHRYSANTHEMUMS DONE BLOOMING (*Chrysanthemum*).—Keep the plants in the pots in a cold frame with the old stems cut down to the surface. Take cuttings in March or April, and these will soon root in a little heat. Such make nice small plants for blooming late in small pots. Shift them into 24-pots in May, and transfer into nine-inch pots in June. Stop them when well rooted to four leaves, and when they have pushed sufficiently stop again to four leaves by pinching out the tips of the shoots. Keep them stopped until the middle of July, then discontinue the stopping process. If you want large specimens pot the suckers in March, otherwise we like to do it in November, place in a cold frame for a few days, then harden off. In potting select the strongest and best rooted short-jointed suckers. Stop them when 6 inches high, and you may stop again in the end of May or beginning of June, and again in the end of that month or beginning of July. The *Mandevilla suaveolens* will most likely bloom another year if you do not cut it in too much, but merely thin out and shorten the shoots a little, giving it abundance of light and keeping it moderately dry at the root during the winter. It is one of the sweetest flowers grown.

PROPAGATING POINSETTIA PULCHERRIMA (*E. M. S.*).—Cuttings of this put in about the middle of July will root freely if the pots are plunged in a hotbed. If they have two joints, one in and one out of the soil, they will do well. The cuttings are best inserted singly in 60-sized pots, in a compost of turfy peat, loam, and leaf mould in equal parts, with a free admixture of silver sand. This will suit established plants; but more sand should be mixed with the soil for the cuttings. The plants thus struck should be potted in six-inch pots, kept near the glass in a moist atmosphere in a stove temperature, and well watered. Cuttings may also be put in February and treated in the same manner, stopping them in May, and much larger and earlier-blooming plants will be the result. It is an intermediate stove plant. There are many berry-bearing plants called Winter Cherries, but that usually known as the Winter Cherry, is *Physalis Alkekengi*. Any of the nurserymen who advertise in our columns can furnish you with double Pansies.

GREEN FLY ON GOOSEBERRY BUSHES (*J. King*).—We were at one time sorely pestered with fly on Currants and others of the *Ribes* family against walls. The fruit was dirty and not fit for use, though larger than that from bushes. We were in the habit of washing our wall trees with a solution of different ingredients at the winter dressing to prevent summer attacks of insects, and with good success tried it on the *Ribes* tribe, as the Gooseberry and Currant. It was made as follows:—One stone quicklime, and 14 lbs. sulphur vivum, 1 peck of soot, 14 lbs. soft soap, with tobacco water made by adding four gallons of water to the tobacco liquor of the tobacco manufacturers, sufficient to form the whole into the consistency of thin paint. With this we painted every branch, upward from the ground, with a common paint brush immediately after the winter pruning, or before the buds began to swell. Birds do not like the buds after this dressing, and the fly was not troublesome in summer, and in many cases did not attack the trees. If it did we syringed the trees during bright weather, just when the fruit was full grown, with tobacco water made by adding six gallons of water to the tobacco liquor of the shops, or by pouring a gallon of boiling water on an ounce of the strongest slug tobacco. The smoke of a large town would not bring on attacks of green fly, for we have grown Gooseberries in such a locality very fine and clean, and we were much assisted in the work by the grossly maltreated house sparrows, which devour green fly, caterpillars, and other garden pests. Preserve such friends as these and you will find them assist in ridding you of your enemy. We should think your Currants will not produce fine fruit if the leaves are taken off the bushes during the height of the growing season, especially if this practice be continued year after year.

GUM IN APRICOT TREES (*Hampshire Hills*).—There is, so far as we know, no care for the gumming of fruit trees in some soils, and the Apricot is very subject to it on the red sandstone, and thin sandy soils with a gravelly subsoil. It will not interfere with bearing further than this, that a diseased branch is liable to die off at any time, and is just as likely to do so when the fruit is nearly ripe as at any other time. The gum which exudes should be removed with a knife, and the place pared down to the fresh bark, and the wound will heal over if the hole be stopped well with clay and cowdung. Though this may prevent the accumulation of gum at that part, the plaster assisting the healing of the wound, yet it will not prevent its exudation from another part of the tree. You will gain nothing by cutting the branches of the Pear tree back, but, on the contrary, lose a number of years in getting the wall covered again. We would insert some buds in the spurs on the lower parts of the branches next summer, and the buds, if they take, will, in a short time, produce fruitful spurs on the lower part of the branches.

BOTTOM HEAT DEFICIENT (B. T. E.).—We think your simplest plan will be to lower your slate a foot or 15 inches, so as to be 2 or 3 inches from the pipes. These two pipes ought to give you enough of bottom heat. Stop the top holes in the slate, and, if necessary, make two or three holes at the bottom of the chamber, near where your return-pipe now is. If you want more piping we think you would require it most for the atmosphere of the house. We presume your pipes in the viney are all right as to level. The simplest way of heating such an arrangement would have been to have taken a flow from the boiler to a cistern at the farther end of the propagating-house—say 2 or 3 feet above the highest piping—and from thence, by plugh, give top or bottom, or viney heat, as required.

HYACINTH CULTURE IN HOLLAND (A. N. Morin).—The articles to which you allude appeared in Nos. 19, 20, 21, 24, and 25, May and June 1853. They have not been republished.

NEW ROSES (H. L.).—Our Number published on Nov. 1 contains a criticism on the new Roses. You can have it free by post if you send four penny postage stamps to our office with your direction.

HEATING A PIT (T. W. U. R.).—Such pits, to be heated with dung, must be provided with linings, if early Melons or Cucumbers are desired. As you wish to have an open area round your pipes for bottom heat, your best plan would be to cover the chamber with slate, within 2 or 3 inches of the pipe. Place 6 inches of open rubble over the slate, beneath the soil, with openings back and front, by pipes or otherwise, to let the heat up. By pouring water into these openings, among the rubble, over the slates, you can have a moist bottom heat and a moist top heat at command, and a dry heat, as you desire. We have no objection to tanks or evaporating-pans, on your pipes, but the above would be the simplest. For early work for such a pit you would need two four-inch pipes for bottom heat, and two for top heat. For late spring, summer, and autumn work, two pipes at bottom would do, if top heat, by means of openings, could be taken when necessary. For winter Cucumbers you would require three bottom and three top pipes. The simplest plan of all would be to have pipes alone for bottom heat, surrounded with clinkers, brickbats, &c., with means for sending water amongst these clinkers and bats when necessary. The reason why so many people fail in obtaining bottom heat from pipes is—the air gets too confined, and thus becomes a non-conductor; the material placed over them also gets too dry, and that becomes a non-conductor as well. It is a mistake to have a mound over such pipes, and expect it to be heated through, unless the air at the bottom of the mass is kept moist and in motion. See answers to other correspondents to-day, and lately, and Mr. Fish's description of heating at Mr. Lane's, of Berkhamstead, last season. There is no difficulty in getting plenty of bottom heat in Mr. Lane's enclosed chambers. Without chambers, with merely open rubble round the pipes, the secrets of success are moist air, and air in motion. These two little facts are, as respects heating by bottom heat, worth the expense of several volumes. The age of monuments, however, is passed, and well passed.

SEX OF ACCUBA (Idem).—The common Accuba japonica of our gardens is the female variety. Mr. Standish has the male variety, introduced by Mr. Fortune.

VINES UNFRUITFUL (Tyro).—If you look back to Mr. Fish's description of border-making at Keele Hall and Trentham, or see what is said on the subject in the "Vine Manual," published at our office, you will see that you could not have done worse than plant the Vines at the bottom of your border, and take the stems in at the bottom of the front wall, as shown in your black ink line. Your red ink line would be preferable, but even that shows the Vine planted too low. As your front wall is 2½ feet high, make your border 2 feet 4 inches in height; place 9 inches of open rubble at the bottom, with a drain in front, and spread out the roots of the young Vines within 4 inches of the surface. Your Apples are small specimens of the old Golden Pippin. They attain four times the size in an orchard-house.

LOBELIA GORDONII (A Lover of Flowers).—Lobelia Gordonii is a good deal in the same way as Paxtoniana. A lot of these Lobelias requires a microscope to distinguish them. We raised seedlings of Paxtoniana last year, and though like, they also differed a little from the parent, and we suspect this will be the case with the others less or more.

SUNDERLAND PUBLIC PARK (M. B.).—We do not know whether the prizes for the plants have been awarded. You had better write to the Town Clerk of Sunderland.

ICE-HOUSE (G. C., Penrith).—We think in your case, if the house is small, the lining with straw would be an advantage, but as it becomes wet it should be withdrawn. For years we have used none, and we thus get rid of much wasting vapour.

LATE VINEY (J. Goodear).—It will be safest to keep your viney shut during frost. You may use it until March or April for wintering bedding plants. You will not start the Vines if you do not raise the temperature above from 40° to 45°. You may wash your Vines with a paint of clay and sulphur. You may do the same with Gishurst at about half a pound to the gallon.

AZALEA LEAVES FALLING (Liverpool).—The treatment you describe is good, only the buds were set or the growth made before the plants were placed outside; a cool house, however, would have been a better position for them, for the sudden changes consequent on their being placed out of doors, and brought in again, have had an injurious effect on the plants. The leaves falling so much is in most instances principally caused by forcing the plants to set their buds early in the season, and long weak growths are the consequence. The leaves fall early because they were formed early and imperfectly. We fear the drainage is not over-perfect, that the plants have been too freely watered, and the soil thus rendered unsuitable for the roots. A temperature of from 40° to 45° from fire heat is quite warm enough for Azaleas in winter. You say you noticed appearances of red spider on the leaves. This is rather uncommon; it was more likely to be thrips. You syringed the leaves with tobacco water, and that has been too strong, and turned the leaves brown—in fact destroyed them. The house should have been fumigated with tobacco, and so filled with the smoke that not a plant could have been seen from the outside. Leave the plants alone now, water only when they require it, and we think they will bloom well after all. Make the drainage more secure after they have bloomed, and pot them if they require it, elevating the necks of the plants a little in the centre of the pots. The buds of the shoots sent were sound, and will bloom we think.

NAMES OF FRUITS (C. R.).—Your Apple is certainly quite distinct from

Ribston Pippin, and is apparently a very excellent keeper, but we cannot say what it is. One of the specimens is exactly like a Ribston in appearance, but the flavour is quite different. (J. B. Z.)—**Pears.**—1, Colmar; 3, Broom-park; 5, Knight's Monarch; 6, Beurré de Rance; 7, Passe Colmar. **Apples.**—2, Ord's; 7, Dutch Mignonette; 8, King of the Pippins; 11, Sam Young; 12, Coe's Golden Drop; 14, Devonshire Queen; 16, Bedfordshire Foundling. The numbers not named are unrecognised. (Montgomery).—The large green Apples are Yorkshire Greening, and the round yellow ones Dumelow's Seedling. (J. M. Miller).—3, Passe Colmar; 4, Beurré d'Aremberg. The others were smashed.

NAMES OF PLANTS (M. P.).—1, Blechnum occidentale minus; 2, Doodia caudata; 3, Goniopteris appendiculatum; 4, Lastrea patens; 5, Asplenium fontanum.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

HAMBURGH FOWLS ARE PROFITABLE.

HAVING kept Gold and Silver-pencilled Hamburg fowls for some years I am able to speak respecting them. As layers they stand alone, never ceasing to lay but at moulting time; and the Golden lay much larger eggs than the Silver, and are healthy, bright, happy birds if allowed freedom, but they will not thrive in confinement. Being obliged to keep mine confined for about five weeks before the grass was cut, though a tolerable yard was allowed to each breed, their feathers became in a most deplorable state. First, the cock lost all the soft down of his hackles, the stump of the feathers remaining. The heads, breasts, and nearly all the feathers of the hens then became diseased. I tried cocoa-nut oil and turmeric rubbed on but to no purpose, and until the moulting season they never recovered their fine plumage. The cock nearly died. They ate well and continued laying, but they were frightful objects to look at. During this time they were well supplied with lettuce and greens, and always allowed to run on the lawn and garden every morning for a short time. I have found half-bred Silver or Gold Hamburgs lay larger eggs, and never offer to sit more than once in a year; and these would be the breed of poultry "CHANTICLEEE" wants as "good egg-producers, hardy, easily reared, and not large." They mix well with the thoroughbred, and do not prevent the exhibition of prize poultry. I should advise a cross of the Dorking and Hamburg, and then putting some of these pullets with the thoroughbred birds. They (Hamburgs) are very easily reared and beautiful when first hatched. Out of thirty or forty I did not lose one this summer.

Very good birds may be bought by answering the advertisements in this Journal and learning the pedigree of the fowls.

A few feathers cut off one wing, leaving the flight or large wing feathers, will not disfigure the Hamburgs, and will prevent their flying over every fence.—SHARP-SPUE.

POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

(Continued from page 502.)

THE ROOSTING AND LAYING ROOM.

THIS should be kept scrupulously clean, swept out daily, and occasionally thoroughly whitewashed. The floor, composed of concrete, ought to be slightly sanded over daily. The sides and ceiling, also the divisions of the nests for laying, should be made of boards well whitewashed. The nest (fig. 5), should be made of earthenware, and partly filled with fine sand or cocoa-nut refuse, and slightly sprinkled over with flowers of sulphur.

Fig. 5.

The roosting-perches should be formed of hot-water pipes, as they are of the Earthenware Nest, of utmost importance to keep the poultry warm during the cold nights, and cool during the hot nights, which will induce continuous egg-laying at a period when eggs are most scarce, whether for hatching or consumption.

Most persons must have observed that even the heaviest fowls will seek to perch nearest the ceiling, and that when roosting their feathers are ruffled or open. This is easily explained by all persons conversant with aërostatic laws—namely, that heated air being lighter than cold air, the former will ascend; consequently the warmest place in a

room will be nearest to the ceiling; and fowls open their feathers when roosting to admit the warm ascending air.

Another important point in the construction of this room is to create perfect ventilation without causing a draught. Now, different gases varying in their specific gravity are formed in this room—namely, carbonic acid, which is a heavy gas and hangs near the floor, ammoniacal gas from the excretions of fowls, and carbureted hydrogen gas from the exhalations of the fowls, both of which are light, and consequently rise to the ceiling. It therefore becomes necessary to adopt a principle of ventilation by which both the heavy and light gases can be got rid of without causing a draught, which would be prejudicial to the health of the fowls. This is accomplished by two pieces of perforated zinc, one opposite the other near the floor, and the same

near the ceiling, and at least 12 inches above the roosting-perches.

THE HATCHING ROOM.

This in my plan is situated above the roosting-room, and is composed of two compartments—the one in which the hen sits, the other where she has a supply of gritty dust to perform her ablutions (see fig. 6). The sides, floor, and ceiling are formed of boards well whitewashed. Light is admitted through a glass door from the passage, over which perforated zinc is fixed to provide for efficient ventilation. The roof is covered with asphalted felt, and the nest ought to be of earthenware, the same as those for laying.

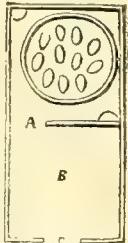

Fig. 6.—Plan of hatching-room.

THE POULTRY HOME AND VINYERY.

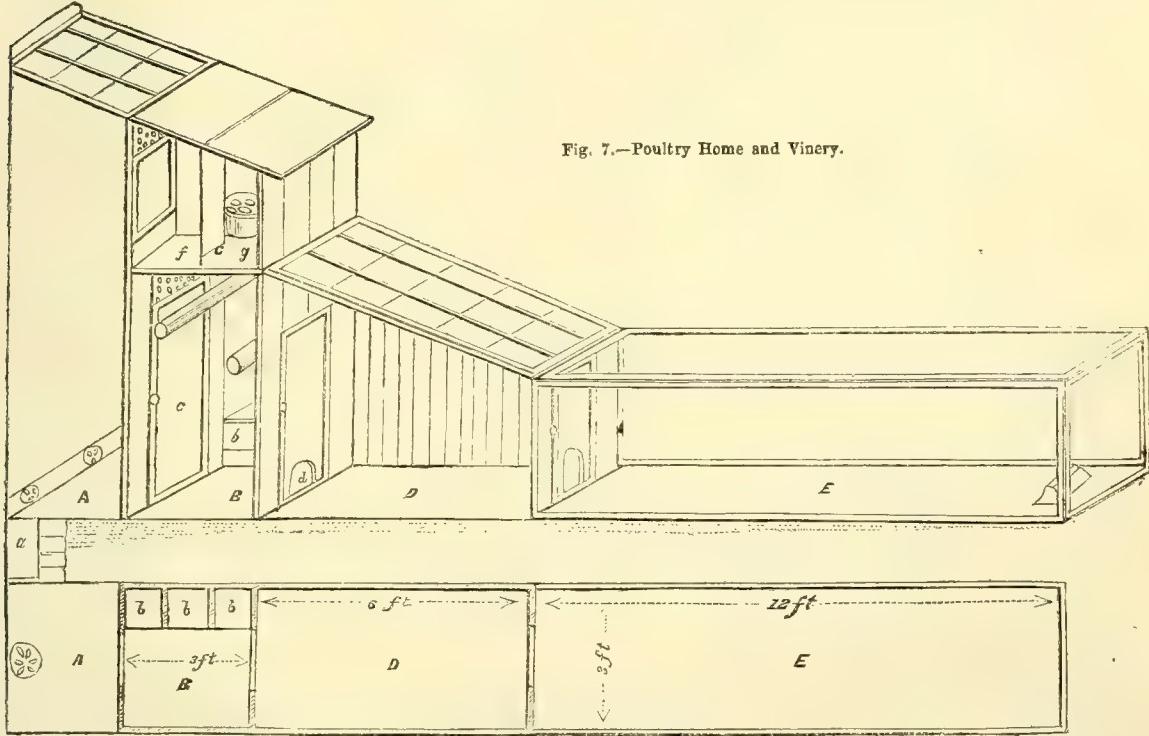

Fig. 7.—Poultry Home and Vinery.

a Is a glass-covered passage running the whole length of the building, and from which communication is obtained by means of doors to all the compartments of the homes on either side. This passage ought to be about 6 feet wide and 8 feet high to the rise of the roof.

b Is a flue formed of bricks and covered-in with paving tiles, with ventilators at certain distances. This flue runs the whole length of the building, and ought to be about 9 inches wide and 15 inches deep. It serves for warming the building by means of hot air, steam, or hot-water pipes; and the admission of heat to the passage is regulated by means of the ventilators.

The floor should be formed of concrete, the sides of whitewashed boards, and the roof of glass, with moveable frames at certain distances to allow of ventilation. This passage can also be turned to profitable account without extra cost by being used as a viney or greenhouse.

c Is the roosting room, about 3 feet square and 6 feet high. The floor should be made of concrete, the sides and ceiling of whitewashed boards. Near the ceiling and to the floor pieces of perforated zinc ought to be fixed opposite one another for the thorough ventilation of this compartment. The partitions of nests, b b b (fig. 8), should be made of whitewashed boards, the top projecting about 3 inches to prevent the droppings falling in. The nests should be made of earthenware in the shape of fig. 5.

d Is a door communicating with the passage, and e with the covered run. In this door an opening ought to be provided with a glazed slide for the egress and ingress of the fowls. In this compartment fowls should be fed in wet weather, and the drinking-fountain ought also to be placed here. The perches where practicable ought to be formed of cast-iron hot-water pipes running the whole length of the building. These can be partly covered with felt, which should be removable for cleaning. These perches should be about 3 and 4 feet from the floor.

e. The hatching-pens are immediately over the roosting-room, and should be 3 feet deep, 18 inches wide, and 2 feet high. This space is divided into two compartments, f and g, the one for the nest and the other for the ablution of the hen in dry gritty dust (see fig. 6). The sides, floor, ceiling, and partition are made of whitewashed boards; the door is glazed with a perforated zinc plate over it for ventilation, and the roof covered with asphalted felt. The nest should be of earthenware, the same as that for laying (see fig. 5), with a layer of sand, which again is covered by a piece of fresh-cut turf, on which the eggs are placed. See "Natural Hatching" in a subsequent paper.

f. The glass-covered run should not be less than 6 feet long, 3 feet wide, 4 feet high to the rise, and 6 feet to the apex or top of the glass frame, which ought to be moveable to admit of ventilation. The sides should be formed of

whitewashed boards; and the floor of about 6 inches deep of gritty dust. A perch can also be fixed in this compartment with advantage.

E. The open run should not be less than 12 feet long, 3 feet wide, and 3 feet high, and the floor made of concrete, as shown in fig. 1. The sides and top should be of galvanised iron netting. It is not, however, advisable to fix wire netting in too great lengths without support, as, with the least strain upon it, it gets out of shape. The plan I recommend for the construction of open runs consists of separate wooden frames 6 feet by 3 feet, on which the wire netting is fixed

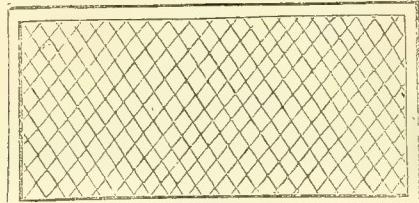

Fig. 9.—Wire Frame.

(see fig. 9), and grooved uprights in which these frames are slid (see figs. 10 and 11). The frames forming the top can

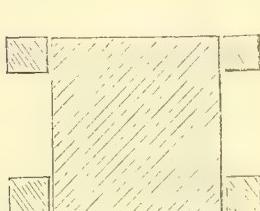

Fig. 10.—Central Upright.

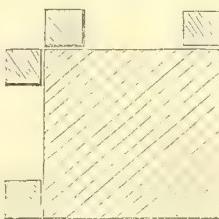

Fig. 11.—Corner Upright.

be joined together by hinges. By adopting this plan the whole run can be removed in a few minutes, or any part can be taken away for repair without interfering with the other, or some spare frames might even be kept in stock to replace those in want of repair.—G. K. GEYELIN, Civil Engineer, London.

(To be continued.)

THE POULTRY CLUB'S CENSURE OF THE BIRMINGHAM SHOW COMMITTEE.

I SEE by a report, printed and sent me by the Secretary of the Poultry Club, that a vote of censure was passed by the meeting on the Birmingham Committee for the appointment of the same Judges as last year at Bingley Hall. I beg to say that, although I took part in the discussion of several subjects at that meeting, the vote was passed after I with many others left the room, and that if I had been present at the time I should have opposed the vote most strongly, as I should have hesitated to censure a body of gentlemen from whom I have always received the greatest courtesy, and whose conduct is always characterised by such thorough fairness and honour, evinced towards exhibitors on all occasions.—JOHN K. FOWLER, Prebendal Farm, Aylesbury.

WHY ARE SHOWS HELD SIMULTANEOUSLY?

In your report of the Leeds Poultry Show, you allude to the fact that the Newport Exhibition was held at the same time, and to the injury which meetings held thus simultaneously inflict upon each other. I am glad to see the subject noticed in your columns.

While on the one hand, we hear complaints both of the non-success of poultry shows, and of their dearth in the south of England, we find on the other hand existing exhibitions jostling one another, nay more, "cutting each other's throats," by seizing with fatal precision the same day for their respective meetings. Last year Basingstoke and Islington were contemporaneous. This very month Birmingham, Brighton, and York, were held at the same time.

Now, it is bad, certainly, for birds to travel from show to

show without an interval of rest, but it is worse for managers to injure each other's chances of success, and for exhibitors to lose half their chances of a prize, owing to the suicidal rivalry of leading shows. Can we not induce some of our managers to vary the monotony which crowds the month of December with incessant and competing shows, by a few exhibitions of old birds in the spring, and young ones in summer and autumn? Will not Islington or Alexandra Park, or the Crystal Palace take the hint? Can we not have a metropolitan show when London is full, and days are lengthening, when moreover a railway journey is not as at this wintry season an act of penance?—BRAHMA POOTRA.

MANCHESTER EXHIBITION OF POULTRY AND PIGEONS.

FOUR years have now passed away since the first show of poultry was held at the Belle Vue Zoological Gardens, Manchester. Year by year this meeting seems to grow more important, and to gain rapidly on public favour; in fact, the aggregate entries of the Show just concluded exceed those of last season by very nearly 130 pens—as strong a proof, perhaps, as could be adduced, that the untiring efforts of the Messrs. Jennison to deserve public support are duly appreciated by exhibitors generally.

The majority of our poultry readers are most probably aware, that the large Music Hall in connection with this establishment, is one of the most eligible and convenient places we can call to mind for the holding of such an exhibition. We may mention, too, the great advantage arising from the proprietors being able to thoroughly warm the whole building by hot-water apparatus, similarly constructed to those in use for horticultural purposes. The advantage arising from this fact, to such poultry as have been long accustomed to great care and attention when at home cannot possibly be overrated, and it was spontaneously acknowledged by several visitors, that the fowls not unfrequently came back from the Manchester Exhibition in actually improved condition to that in which their owners had forwarded them. "To serve all alike without respect to rank or station, the printed rules being always adopted," is punctiliously observed throughout the whole proceedings, and, consequently, when one knows that these regulations will be enforced, very few try to evade them, and general satisfaction ensues. We purpose making a few passing remarks on the classes generally.

Silver Grey Dorkings are the variety that head the list, and we cannot help feeling regret so beautiful a breed of poultry seem so little supported. The popular notion we are aware is, they are more tender to rear than the common-coloured Dorking; but our own experience in a run holding generally about a hundred specimens, convinces us they are equally hardy with other Dorkings, and that they lay more abundantly, which is no inconsiderable recommendation. The classes for Coloured Dorkings, except Silver Greys, were, however, exceedingly well filled at Manchester; the choicest specimens from the stockyards of Viscountess Holmesdale and Captain Hornby here vied with each other in close rivalry. It would be useless to hope for a better display. It was in these classes that Lady Holmesdale's adult Dorkings secured not only the first position for merit in their respective class, but also the extra silver cup given to the best pen of fowls in the Exhibition regardless of variety. About forty of the best first-prize pens were selected as fitting competitors for this principal premium, and the invidious and delicate task of such an award was deputed by the Messrs. Jennison to Mr. Hewitt, of Birmingham, alone; those gentlemen thus carrying out thereby the principle of "voting for the Judges," as pursued by the exhibitors at the time of making their entries, by individual endorsement on each entry paper. This fine pen of Dorkings is certainly one of the best pens we have seen for many years past, and was again shown in first-rate condition. We cannot pass over these classes without remarking that, perhaps, the competition in the Grey Dorking classes throughout was never excelled, consequently those Dorking breeders who missed the opportunity thus afforded lost a treat of no common character.

The Black Spanish were numerous, and shown in first-rate

condition. We are glad to see that the now old-fashioned corrugated faces once so coveted, are quite fallen in public estimation. That it is a direct step to improvement admits of no doubt, the exquisitely kid-like face, soft and unstained as a lady's dress glove, being infinitely more beautiful than the so-called "cauliflower" faces, that at three years old generally deprive the male birds not only of the power of vision, but even of feeding themselves at all without special assistance.

The classes for *Crève-Cœur* fowls may be regarded as an entire failure, for only two pens (both very good, however), were entered in the general class; and the class for *Single Cocks* was entirely empty.

The *Cochin* classes were almost a counterpart of the Birmingham Exhibition, Captain Heaton still standing a-head, but pressed even more closely than ever by his former competitors. Few fowls "ever worked so hard," to use the expressive term of a bystander, as these magnificent pens of poultry have done during the last few weeks. It is evidently telling rapidly on constitution, and to give these worthy antagonists a few weeks' rest to invigorate them before the fast-coming breeding season, would be a most prudent step for their respective owners, bearing so materially as it inevitably must do, on the robust character of next year's chickens. White Cochins were few as to entries, but little from perfection as to character; and the Partridge-coloured Cochins and also the *Brahmas* were good. The classes for the last-named breed were divided for light and dark-coloured birds.

The Silver-spangled *Polands* were quite the best of the Poland tribes exhibited, but the Black Hamburghs were very deficient specimens.

In *Hamburghs* we regretted to find several very "rousy" pens exhibited, capital birds, but quite out of place where they then were, even if considered only in common justice to the poultry in their vicinity. Silver-spangled Hamburghs were a most meritorious feature of the Show, but the Golden-spangled variety were unusually faulty in combs. Great care and attention to this point is necessary to success.

The Game fowls were a capital display, a great portion of them being evidently in the most perfect condition that could be desired, hitherto unaccustomed to the exhibition pen, and evidently competing to no mean advantage thereby over those that have been of late quite overtaxed by the combined trials of excessive travelling and close confinement.

The Game *Bantams* were especially good, as were the *Turkeys*, *Ducks*, and *Geese*. Among the latter were shown some extraordinarily fine specimens of the *Sebastopol Geese*, and a pen of *Brent Geese*, in so exquisite condition, that the feathers shone, and were smooth as the skin of a living seal. They attracted great attention.

The *Pigeons* were numerous and very good, and embraced the most perfect selections from all our principal breeders, and the accommodation for these public favourites could not have been improved.

DORKINGS (Silver Grey).—First, R. W. Boyle, Dundrum, Dublin. Second, D. Parsons, Cuerden, Preston. Highly Commended, Rev. T. O'Grady, Ashbourne. *Chickens*.—First, Rev. T. O'Grady. Second, D. Harding, Middlewich, Cheshire. Commended, Rev. J. F. Newton, Kirby-in-Cleveland.

DORKINGS (Silver Grey).—Cockerel.—First, M. Heddley, Red Hill, Surrey. Second, T. Statter, Stand Hill, Manchester. *Pullets*.—Prize, T. Statter.

DORKINGS (Coloured, except Silver Grey).—First, Viscountess Holmesdale, Staplehurst, Kent. Second and Third, Captain W. Hornby, Prescott. Highly Commended, Rev. J. F. Newton. *Chickens*.—First and Second, Captain W. Hornby. Third, Rev. J. F. Newton, Kirby-in-Cleveland, Yorkshire. Highly Commended, Sir St. G. Gore, Bart. Commended, W. A. Taylor; D. Parsons, Cuerden, Preston.

DORKINGS (Coloured, except Silver Grey).—*Hens or Pullets*.—First, Viscountess Holmesdale. Second, Sir St. G. Gore, Bart, Hopton Hall, Derbyshire. *Cock*.—First, Viscountess Holmesdale. Second, E. Tudman, Salop. Third, Captain W. Hornby. Commended, Rev. J. G. A. Baker, Biggleswade. *Cockerel*.—First, E. Shaw, Oswestry. Second, E. Tudman. Commended, Miss S. J. Whitham, Brierfield, Marsden, Lancashire. Highly Commended, Viscountess Holmesdale.

DORKINGS (White).—First, D. Parsons. Second, H. Savile, Ollerton. Highly Commended, Sir St. G. Gore, Bart.

CRÈVE-CŒUR.—Prize, J. Harrison, Blackpool. Commended, J. K. Fowler, Aylesbury.

SPANISH.—First, Viscountess Holmesdale. Second, J. Garlick, Liverpool. Highly Commended, J. R. Rodbard, Wrington, Bristol. *Chickens*.—First, E. Jones, Clifton, Bristol. Second, Viscountess Holmesdale. Third, J. R. Rodbard. Highly Commended, Master P. H. Stevens, Macclesfield. Commended, E. Brown, Sheffield; J. Garlick, Liverpool.

SPANISH.—*Cock*.—First and Second, H. Lane, Bristol. Third, T. P. Wood, jun., Chesterfield. Commended, H. C. Mobbs; J. Smith, Openshaw. *Hens*.—First, H. Lane. Second, Viscountess Holmesdale, Staplehurst, Kent. Commended, S. Robson, Brotherton, Yorkshire; R. B. Postans, Brentwood. *Cockerel*.—First, S. Robson, Brotherton. Second, R. Paton.

Third, H. Beldon, Bingley. Commended, J. L. Lowdes, Hartwell, Aylesbury; E. Brown, Sheffield. *Pullets*.—First, H. Lane.

COCHIN-CHINA (Cinnamon and Buff).—First, Captain H. Heaton, Manchester. Second, H. Bates, Birmingham. Third, C. T. Bishop, Lenton, Nottingham. Highly Commended, R. Adams, Handsworth, Birmingham. Commended, C. T. Bishop. *Chickens*.—First, J. Nelson, Heaton Mersey, Manchester. Second, R. Adams. Third, Captain H. Heaton. Highly Commended, W. F. Zurhorst, Donnybrook, Dublin; J. Shawcross, West Gorton, Manchester.

COCHIN-CHINA (Cinnamon and Buff).—*Cock*.—First, W. F. Zurhorst, Donnybrook, Dublin. Second, J. Smith, Openshaw. Third, H. Ogden, Ashton-under-Lyne. Highly Commended, E. Bemrose, sen.; J. Kershaw, Mossley. Commended, C. Kershaw, Ashton-under-Lyne; Captain H. Heaton, Lower Broughton, Manchester; J. Shawcross, West Gorton, Manchester. *Pullets*.—First, Captain H. Heaton. Second, C. T. Bishop, Lenton, Nottingham. Third, T. Stretch, Ormskirk. Highly Commended, C. T. Bishop; J. Nelson.

COCHIN-CHINA (Brown and Partridge-feathered).—First, E. Tudman, Whitchurch, Salop. Second, C. Kershaw, Ashton-under-Lyne. Highly Commended, J. Stephens, Wallsall, Birmingham; T. Stretch, Ormskirk. *Chickens*.—First, E. Tudman. Second, C. E. Riddale, Skircoat, Halifax. Third, C. Durham, Manchester. Highly Commended, W. A. Taylor, Manchester. Commended, T. Stretch.

COCHIN-CHINA (Brown and Partridge-feathered).—*Hens or Pullets*.—First, C. W. Brierley, Middleton. Second, E. Tudman, Whitchurch, Salop. Highly Commended, J. R. Rodbard, Wrington, Bristol. *Cockerel*.—First, J. Elliott, West Leigh, Lancashire. Second, T. Bott, Bury, Lancashire. Third, E. Tudman. Highly Commended, W. H. Kershaw, Ashton-under-Lyne. Commanded, E. Tudman; J. Ashcroft, Liverpool.

COCHIN-CHINA (White).—First, R. Chase, Birmingham. Second, G. Lamb, Compton, Wolverhampton. Highly Commended, Rev. F. Taylor, Kirby-Lonsdale. *Cock*.—First, G. Lamb. Second, R. Chase. Highly Commended, Rev. F. Taylor. Commanded, W. Copple, Prescot.

BRAMHA POOTRA (Light).—First and Commended, J. Pares, Chertsey. *Chickens*.—First, J. Pares. Second, F. Crook, Forest Hill, London.

BRAMHA POOTRA (Dark).—First, H. Lacy, Lacy House, Hebden Bridge. Second, W. Hargreaves, Bacup. Third, R. W. Boyle, Dundrum, Dublin. Commended, J. B. Stevens, Macclesfield. *Chickens*.—First, H. Lacy. Second, J. K. Fowler, Aylesbury. Third, R. W. Boyle. Commanded, W. A. Taylor, Manchester; H. Lacy. *Cockerel*.—First, T. Statter, Stand Hill, Manchester. Second, J. Poole, Ulverstone, Lancashire. Highly Commended, W. Hargreaves. Commanded, H. Lacy.

POLISH (Silver).—First, H. Beldon, Gilstead, Bingley, Yorkshire. Second, J. Heath, Cheshire. Highly Commended, J. Percival, Harborne, Birmingham.

HAMBURGS (Black).—First, J. Hope, Oldham. Second, R. F. Goodwin, Middleton. *Chickens*.—First, R. F. Goodwin. Second, H. Savile, Notts. *Cork*.—First, H. Beldon, Gilstead, Yorkshire. Commanded, W. K. Duxbury, Leeds.

HAMBURG (Golden-pencilled).—First, T. Wrigley, sen., Tonge, Middleton. Second, J. E. Powers, Biggleswade, Beds. Commended, J. Grundy, Wrigley, Manchester. *Chickens*.—First and Second, F. Pitts, jun., Isle of Wight. Third Miss M. A. Fielding, Newchurch, Manchester. Highly Commended, E. Bemrose, sen.; Sir St. G. Gore, Bart, Hopton Hall, Derbyshire. Commanded, J. Moss, West Gorton; J. Gleave, Cheshire. *Cockerel*.—First, T. Wrigley, jun. Second, Rev. R. Roy, Worcester. Third, J. E. Powers. Commanded, F. Pitts, jun.; C. Tattersall.

HAMBURG (Silver-pencilled).—First, Sir St. G. Gore, Bart. *Chickens*.—First, Sir St. G. Gore, Bart. Second, W. Bradley, Worcester. Third, Miss M. A. Fielding, Newchurch, near Manchester. *Cockerel*.—First, D. Illingworth, Burley, Yorkshire. Second, H. Charnock, Accrington.

HAMBURG (Golden-spangled).—First, I. Davies, Birmingham. Second, Sir St. G. Gore, Bart. Third, N. Marlor, Denton. Highly Commended, S. H. Hyde, Ashton-under-Lyne. Commanded, J. Pickles, Slaithwaite. *Chickens*.—First, Miss E. Marlor, Denton. Second, J. Roe, Hadfield. Third, M. H. Broadhead, Holmfirth. Highly Commended, J. Buckley, Ashton-under-Lyne; W. H. Nicholls, Sale, near Manchester; Sir St. G. Gore, Bart. *Cockerel*.—First, J. Mellor, Slaithwaite. Second, J. Roe. Third, Sir St. G. Gore, Bart. Commanded, Miss A. A. Roe, Hadfield; C. Broadbent, Saddleworth.

HAMBURGH (Silver-spangled).—First, Sir St. G. Gore, Bart. Commanded, E. T. Holden, Walsall, near Birmingham. *Chickens*.—First, Sir St. G. Gore, Bart. Second and Third, J. Fielding, Newchurch, Manchester. *Cockerel*.—First, Sir St. G. Gore, Bart. Second, J. Fielding.

HAMBURGH (Spangled).—*Hens*.—First, Miss A. A. Roe, Hadfield. Second, S. H. Hyde, Ashton-under-Lyne. Third, J. Beesley, Sale, Cheshire. Highly Commended, H. Beldon, Gilstead; W. Cooper, Helmsley. Commanded, W. Cooper; W. K. Duxbury, Leeds. *Pullets*.—First, J. Wright, Melton Mowbray. Second, E. Hyde, Ashton-under-Lyne.

GAME FOWL (Black-breasted Reds).—First, J. Halsall, Ince, Wigan. Second, Sir St. G. Gore, Bart. Third, J. Fletcher, Stoneclough, Manchester. Highly Commended, J. H. Williams, Welshpool; W. K. Duxbury, Leeds. *Cock*.—First, W. Gammon, Thornton-le-Moors, Chester. Second, Sir St. G. Gore, Bart. Third, J. H. Williams. Highly Commended, J. Smith, Breeder Hills, Grantham. *Chickens*.—First, J. Halsall. Second, H. Thompson, Milnethorpe, Westmoreland. *Cockerel*.—First, W. Gammon. Second, Sir St. G. Gore, Bart.

GAME FOWL (Brown and other Reds, except Black-breasted).—First, J. Smith, Breeder Hills. Second, T. West, St. Helens, Lancashire. Third, J. Fletcher, Stoneclough, Manchester. Highly Commended, T. Statter, Stand Hill, Manchester. *Cock*.—First, J. Smith. Second, T. Statter. Third, R. Swift, Southwell, Notts. Highly Commended, N. Grimshaw, Burnley; W. Galley, Nantwich; E. Bowens, Nantwich. *Chickens*.—First, T. West, Second, J. Fletcher. Third, E. Aykroyd, Bradford. Highly Commended, M. Billing, jun., Erdington, Birmingham. *Cockerel*.—First, M. Billing, jun. Second, T. Statter. Third, N. Grimshaw.

GAME (Black-breasted and other Reds).—*Hens*.—First, C. W. Brierley, Middleton. Second, G. Clements, Birmingham. Third, C. B. Kennedy, Ulverston. *Pullets*.—First, J. H. Cock, Worcester. Second, T. West, St. Helen's. Third, H. Backhouse, Blackburn. Fourth, J. Halsall, Ince, Wigan.

GAME FOWL (Duckwings and other Greys and Blues).—First, Sir St. G. Gore, Bart. Second, J. Fletcher, Stoneclough. Third, S. Matthew, Stowmarket. *Chickens*.—First, Sir St. G. Gore, Bart. Second, J. Halsall, Ince, Wigan. Third, E. Aykroyd, Bradford.

GAME (except Black-breasted and other Reds).—*Cock*.—First, M. Billing,

jun., Erdington, Birmingham. Second, Sir St. G. Gore, Bart., Hopton Hall. Third, S. H. Walwyn. Hen.—First, J. Halsall, Ince, Wigan. Second, Mrs. E. Whittam. Cockerel.—Prize, W. K. Duxbury, Leeds.

GAME (White and Piles).—First, J. Fletcher, Stoneclough. Second, Sir St. G. Gore, Bart. Chickens.—Prize, J. Fletcher. Cockerel.—First, J. Fletcher. Second, H. Thompson Milnethorpe.

GAME BANTAMS (Black-breasted and other Reds).—Chickens.—First, J. Hilton, Ashton-under-Lyne. Second and Third, J. Munn, Newchurch. Fourth, R. Swift, Southwell. Highly Commended, Sir St. G. Gore, Bart., Hopton Hall; R. B. Postans, Brentwood.

GAME BANTAMS (Any other variety).—Chickens.—First, E. Mapplebeck, Moseley, Birmingham. Second, R. Hawksley, jun., Southwell.

GAME BANTAM COCKS.—First, C. W. Brierley, Middleton. Second, Sir St. G. Gore, Bart. Third, G. Smith, Staveley, Chesterfield. Cockerel.—First, W. Brierley. Second, W. Gamon, Thornton-le-Moors. Third, Miss Crawford, Farnsfield. Highly Commended, G. Smith.

BANTAMS (White, Clean-legged).—First, E. Mapplebeck, Moseley. Second, Miss K. Charlton, Bradford.

BANTAMS (Black, Clean-legged).—Chickens.—First, Miss K. Charlton, Bradford. Highly Commended, F. Pittis, jun., Isle of Wight.

BANTAMS (Any other variety).—First, W. J. Cope, Barnsley (Pekin Bantams). Second, P. W. Story, Daventry (White Feathered-legged). Highly Commended, H. Salvile, Ollerton, Notts (Japanese Silky).

DUCKS (White Aylesbury).—First and Highly Commended, J. K. Fowler, Aylesbury. Second, Sir R. Clifton, Bart., Clifton Hall, Notts.

DUCKS (Rouen).—First, R. W. Boyle, Duadrum. Second, J. Holme, Knowsley. Third, C. P. Ackers, Bickershaw, Wigan. Fourth, Sir St. G. Gore, Bart. Highly Commended, J. Nelson, Heaton Mersey.

DUCKS (Black East Indian).—First and Second, J. W. Kelleway, Isle of Wight. Third, F. W. Earle, Frescot.

DUCKS (Any other variety).—First, T. H. D. Bayly, Biggleswade (Brown Call). Second, C. P. Ackers, Bickershaw, Wigan (Brown Call).

ORNAMENTAL WATER FOWL.—First, J. Jennison, Zoological Gardens, Manchester (Carolinias). Second and Highly Commended, H. Savile, Ollerton, Notts (Manderins, Sebastopol Geese, and Carolinas).

GEES (White).—First, W. Kershaw, Heywood, Manchester. Second, Mrs. M. Seemons, Aylesbury. Highly Commended, J. Brundrett, jun., Chorlton-cum-Hardy, Manchester; W. K. Duxbury, Leeds.

GEES (Grey and Mottled).—First, R. W. Boyle, Dundrum.

TURKEYS.—First, J. R. Wood, Lower Crumpsall, Manchester. Highly Commended, J. Wood, Wigan. Poults.—First, J. Smith, Breeder Hills. Second, R. W. Boyle, Dundrum. Highly Commended, W. Wright, Fulbourne, Cambridgehire.

EXTRA STOCK (Any other variety).—First, E. Jones, Clifton, Bristol (Silver-faced Bantams). Second and Third, Mrs. E. Haig, Litchfield (Magpie Tarifans).

PIGEONS.

POWTERS.—First and Second, P. Eden, Salford.

CARRIERS (Black).—Cock.—First, F. Else, Bayswater, London. Second and Third, P. Eden, Salford. Hen.—First, F. Else. Second and Third, P. Eden.

CARRIERS (Any other colour).—Cock.—First, P. Eden, Salford. Second, H. Morton, Macclesfield. Third, C. J. Samuels, Birch Lane, Longsight. Hen.—First, F. Else, Bayswater, London. Second, P. Eden. Third, A. P. Leite, Manchester. Commended, H. Morton; F. Else.

DRAGGONS.—First, F. H. Snushall, Gedney, near Long Sutton. Second, J. Percival, Peckham, Surrey. Third, H. Yardley, Birmingham. Commended, W. Woolley, Cheshire; H. Magson, Hollingworth, near Manchester; S. A. Taylor, Birmingham.

JACOBINS.—First and Third, J. Hockenhull, Nantwich. Second, T. H. Ridpath, Rusholme, Manchester. Highly Commended, T. H. Ridpath.

NUNS.—First, F. Else, Bayswater, London. Second, T. H. Ridpath, Rusholme, Manchester. Third, E. Mapplebeck, Woodfield, near Birmingham. Commended, J. W. Edge, Aston New Town, Birmingham.

RUNTS.—First and Second, J. Baily, jun., Mount Street, London. Highly Commended, J. Baily, jun.

BARBES.—First and Second, P. Eden, Salford. Third, A. P. Leite, Manchester. Very Highly Commended, W. Woolley, Banbury, Cheshire.

TURBITS.—First, W. Edge, Ashton New Town, Manchester. Second, E. Mapplebeck, Woodfield, near Manchester. Very Highly Commended, H. Yardley, Birmingham.

OWLS.—First and Third, S. Sanday, Holme Pierrepont, Notts. Second, P. Eden, Salford, Notts. Highly Commended, P. Eden.

TRUMPETERS.—First, S. A. Taylor, Lozells, Birmingham. Second, F. Else, Bayswater, London. Third, W. H. C. Oates, Besthorpe, Newark, Notts.

FANTAILS.—First, F. Else, Bayswater, London. Second, H. Yardley, Birmingham. Commended, J. Baily, jun., Mount Street, London.

TUMBLERS (Almond).—First, F. Else, Bayswater, London. Second, P. Eden, Salford. Highly Commended, P. Eden.

TUMBLERS (Any other variety).—First and Second, P. Eden, Salford. Highly Commended, W. Leyland, Altringham.

BEARDS.—First, W. H. C. Oates, Besthorpe, Newark, Notts. Second, C. E. Samuels, Birch Lane, Longsight. Commended, F. Else, Bayswater, London.

ANY OTHER VARIETY.—First, A. P. Leite (Laced Fantails). Second Rt. Hon. the Countess of Derby (Isabels). Third, H. Yardley, Birmingham (Satinettes). Extra Prize, T. H. Ridpath, Rusholme, Manchester (Balds). Commended, J. Baily, jun., Mount Street, London (Priests).

RAFFTS.

BLACK AND WHITE.—First, H. Handford, Wilford, Notts. Second, A. Firth, Hyde.

YELLOW AND WHITE.—First, W. Howell, Harborne, Birmingham. Second, W. Stelfox, Greenheys, Manchester. Highly Commended, T. H. Ridpath, Rusholme, Manchester.

TORTOISESHILL.—First, A. Cattley, York. Second, T. H. Ridpath, Rusholme, Manchester. Highly Commended, W. Stelfox, Greenheys, Manchester.

BLUE AND WHITE.—First, Messrs. Hall & Co., Plumstead, Kent. Second, W. Hall, Leek, Staffordshire.

GREY AND WHITE.—First, A. Firth, Hyde. Second, T. Tunaby, Kensington, Derby.

SILK COLOUR.—First and Second, T. H. Ridpath, Rusholme, Manchester. LONGEST EAES.—Prize, J. Read, Coventry. Highly Commended, W. Stelfox, Greenheys, Manchester.

HEAVIEST WEIGHT.—Prize, E. E. M. Royds, Greenhill, Rochdale. FOREIGN RABBITS.—First and Second, J. Buchanan, Hertford.

JUDGES.—POULTRY: Game, Game Bantams, Ducks, Geese, Turkeys, Ornamental Water Fowl, &c., Mr. Douglas, Mr. Chaloner, and Mr. Adams. Dorking, Spanish, Cochin-China, Brahma Pootra, Crèvecœur, Polish, and Hamburg, Mr. Hewitt and Mr. Dixon. Pigeons: Dr. Cottle, Cheltenham. Rabbits: Mr. Owen, London.

LORD TREDEGAR'S POULTRY SHOW.

DECEMBER 13TH.

AMONG the birds were contributions from almost all parts of the kingdom, and the prize list will show that the competitors included the first poultry fanciers of the day. Many of the pens were really beautiful and merited the admiration they received. As usual the shed was crammed during the whole time it was open. As Mr. Logan took the champion prize for cattle, it is gratifying to find that in the poultry also, the prize given to the exhibitor who obtains the greatest number of prizes, has, notwithstanding the close competition, been retained in our own neighbourhood, it having fallen to the lot of our townsman, Mr. R. H. Nicholas, whom we have pleasure in congratulating upon his success. There was very nearly a tie between Mr. Nicholas and Mr. Fowler, the celebrated Duck breeder of Aylesbury—the former gentleman having sixty-four points, and the latter fifty-nine, the prize being reckoned by points, of which five are counted for a first prize, and so in proportion, a point less for each next inferior prize.

The following prizes were awarded:—

A Piece of Plate value Five Guineas, given by the Poultry Committee, to the Exhibitor taking the greatest number of Prizes, R. H. Nicholas, Malpas, Newport.

SPANISH.—First, R. H. Nicholas, Malpas, Newport. Second, J. K. Fowler, Prebendal Farm, Aylesbury. Commended, Mrs. N. Grenville, Butleigh Court, Glastonbury; J. Llewellyn, Caerphilly, Cardiff.

DORKING (Co'ned).—First, J. K. Fowler, Prebendal Farm, Aylesbury. Second, J. Buckley, Penyall House, Llanelli. Highly Commended, Hon. F. C. Morgan, Rupert Castle, Glamorgan; C. Lyne, Brynhyfryd, Newport; J. Logan, Maindee House, Newport.

DORKING (White).—First and Second, R. H. Nicholas, Malpas, Newport. Commended, H. J. Evans, Brecon Old Bank, Cardiff.

GAME (Black or Brown-breasted Reds).—First, M. Billing, jun., Wood End, Erdington, Birmingham. Second, J. H. Braikenridge, Chew Magna, Bristol. Highly Commended, R. H. Nicholas, Newport; J. Llewellyn, Caerphilly, Glamorgan. Commended, W. K. Duxbury, Leeds.

GAME (Duckwings or other Greys and Blues).—First, J. B. Chene, Coalbrookdale, Shropshire. Second, Messrs. J. A. & W. H. Briggs, Prospect House, Manningham, Bradford. Commended, F. King, Wellington, Salop.

GAME (Any other variety).—First, J. Llewellyn, Caerphilly, Cardiff. Second, T. Fletcher, Great Malvern.

COCHIN-CHINA (Coloured).—First, W. Bowly, Siddington House, Cirencester. Second, J. Gardiner, Bristol. Commended, Mrs. E. Everett, Monmouth; W. Bradley, Worcester.

COCHIN-CHINA (White).—First, F. W. Zurhorst, Belville, Donnybrook, Dublin. Second, J. Gardiner, Bristol. Commended, Mrs. E. Everett, Monmouth.

BRAMA POOTRA.—First, J. Hinton, Hinton, Bath. Second, J. K. Fowler, Aylesbury. Commended, Right Hon. Lord Tredegar, Tredegar Park; J. Hinton; E. Pigeon, Lymptonstone, Exeter.

HAMBURGS (Gold or Silver-pencilled).—First, J. A. & W. H. Briggs, Manningham, Bradford. Second, J. Holland, Chesnut Walk, Worcester. Third, J. K. Fowler, Aylesbury. Commended, W. Clarke, Wellington, Shropshire; T. Fletcher, Great Malvern.

HAMBURGS (Gold or Silver-spangled).—First, W. K. Duxbury, Leeds. Second and Third, T. Davies, Stow Hill, Newport. Highly Commended, T. Davies.

POLANDS (Black with White Crests).—First, R. H. Nicholas, Malpas, Newport. Second, T. Fletcher, Great Malvern.

POLANDS (Golden or Silver).—First, R. H. Nicholas, Malpas, Newport. Second, J. Hinton, Hinton, Bath. Commended, W. Pickford, Clifton Place, Newport.

MALAYS OR INDIAN GAME.—First and Second, J. J. Fox, Devizes, Wilts. Highly Commended, J. Hinton, Hinton, Bath.

BANTAMS (Game).—First, J. K. Fowler, Aylesbury. Second, C. Cambridge, Colborne Villa, Coronation Road, Bristol. Highly Commended, E. Pigeon, Lymptonstone, Exeter. Commended, Mrs. E. Everett, Monmouth.

BANTAMS (Black or White).—First and Second, T. Davies, Newport.

BANTAMS (Any other variety).—First, Miss G. Everett, Gibraltar Cottage, Monmouth. Second, R. H. Nicholas, Malpas, Newport.

ANY OTHER DISTINCT BREED.—First and Second, R. H. Nicholas, Malpas, Newport. Third, F. W. Zurhorst, Belville, Donnybrook, Dublin. Fourth, Miss Brown, Hardwick House, Chepstow. Fifth, J. K. Fowler, Aylesbury. Commended, E. Pigeon, Lymptonstone, Exeter (La Flèche); R. H. Nicholas (Black Minorcas).

GUINEA FOWLS.—First, J. K. Fowler, Aylesbury. Second, R. H. Nicholas, Malpas, Newport. Commended, Sir G. Walker, Bart., Castletown, Cardiff; S. Lang, jun., the Shrubbery, Redland, Bristol.

DUCKS (Aylesbury).—First, J. K. Fowler, Aylesbury. Second, J. Pye, Spitty Farm, Abergavenny. Highly Commended, J. Logan, Maindee House, Newport; J. K. Fowler, Commended.

DUCKS (Rouen).—First, J. K. Fowler, Aylesbury. Second, R. H. Nicholas, Malpas, Newport. Highly Commended, J. Logan, Newport; S. Lang, Redland, Bristol. Commended, W. Stephens, Higham Green, Gloucester.

GERSEZ.—First, R. Rees, Coalbrook Cottage, Abergavenny. Second, J. K. Fowler, Aylesbury. Highly Commended, R. Rees; J. K. Fowler; A. Cuthbertson, Llangibby.

TURKEYS.—First, Miss J. Milward, Newton St. Loe, Somerset. Second, J. K. Fowler, Aylesbury. Highly Commended, F. C. Morgan, Ruperra Castle, Glamorgan. Commended, F. C. Morgan; C. Lyne, Brynhyfrid, Newport; H. J. Evans, Brecon Old Bank, Cardiff.

SELLING CLASS (For Fowls of any age).—First, R. H. Nicholas, Newport (Hampburghs). Second, J. Hinton, Hinton, Bath (Brahma Pootra). Third, E. Shaw, Plas Wilmot, Oswestry (Grey Dorkings). Commended, R. H. Nicholas, Newport (Golden Polands and Silver-pencilled Hampburghs); J. Hinton, Hinton, Bath (Silver Polands); W. K. Duxbury, Leeds (Hampburghs); Messrs. J. A. & W. H. Briggs, Manningham, Bradford.

SWEETSTAKES FOR SINGLE COCKS.

SPANISH.—First, J. K. Fowler, Aylesbury. Second, R. H. Nicholas, Malpas, Newport.

DORKING.—Prize, E. Shaw, Plas Wilmot, Oswestry. Highly Commended, J. Logan, Maindean House, Newport.

GAME.—Prize, G. S. Sainsbury, Devizes. Highly Commended, J. B. Chunn, Coalbrookdale, Shropshire. Commended, R. H. Nicholas, Malpas, Newport.

COCHIN-CHINA.—Prize, J. K. Fowler, Aylesbury.

BANTAM (Game).—First, R. H. Nicholas, Malpas, Newport. Second, J. K. Fowler, Aylesbury.

ANY OTHER VARIETY.—Prize, R. H. Nicholas, Malpas, Newport (Brahma Pootra). Highly Commended, E. Pigeon, Lympstone, Exeter (Brahma Pootra).

COTTAGERS' PRIZES.

FOWLS.—First and Third, T. Thomas, Machen Fach, Newport (Red and Pile Game). Second, G. Boundy, Malpas, Newport (Silver-pencilled Hampburghs). Fourth, Mrs. E. Ford, Malpas, Newport (Golden-spangled Hampburghs). Highly Commended, W. Jenkins, Malpas (Dorking).

DUCKS.—First and Fourth, G. Boundy, Malpas, Newport (Aylesbury). Second, W. Reed, Malpas, Newport (Aylesbury). Third, J. Thomas, Pontnewydd, Pontypool (Aylesbury).

PIGEONS.

CARRIERS.—First, H. Yardley, Market Hall, Birmingham. Second, C. Bulpin, River Side, Bridgwater. Highly Commended, C. Phillips, jun., Newport.

POWTERS.—First, H. Yardley, Birmingham. Second, G. S. Sainsbury, Devizes, Wilts. Commended, C. Bulpin, Bridgwater; J. W. Edge, Aston New Town, Birmingham; C. Phillips, jun., Newport; E. Pigeon, Lympstone, Exeter.

TUMBLERS.—First, H. Yardley, Birmingham. Second, F. Barfoot, Newport. Highly Commended, W. Bowly, Siddington House, Cirencester; J. W. Edge, Aston New Town, Birmingham.

FANTAILS.—First, T. Rowe, Newport. Second, Miss J. Milward, Newton St. Loe, Somerset. Highly Commended, H. Yardley, Birmingham; G. S. Sainsbury, Devizes, Wilts.

ANY OTHER VARIETY.—First, E. Pigeon, Lympstone, Exeter (Magpies). Second and Third, H. Yardley, Birmingham. Highly Commended, E. Pigeon, Lympstone, Exeter (Turbits).

Judge for the Poultry, Mr. Angus Sutherland, Burnley Lancashire.—(Monmouth Merlin.)

NORTH BRITISH COLUMBIAN SOCIETY.

This Society held their sixth annual Exhibition of Fancy Pigeons and Canaries in the Trades Hall, Glassford Street, Glasgow, on the 23rd and 24th December. We have only room for the awards; our remarks will appear next week.

POWTERS (Pied, except Yellows).—Medal and Second, M. Stuart, Glasgow (Blacks and Blues). Third, J. Muir, Glasgow (Blacks). Very Highly Commended, W. Lightbody, Glasgow (Blues). Highly Commended, D. Stewart, Perth (Blues).

POWTERS (Yellow Pied).—Medal, G. Ure, Dundee. Very Highly Commended, J. Wallace, Glasgow. Highly Commended, H. Simpson, Newark.

POWTERS (White).—Medal, J. Wallace, Glasgow. Highly Commended, G. Ure, Dundee; R. Fulton, London.

POWTERS (Black Cocks).—First, G. Ure, Dundee. Second and Highly Commended, J. Montgomery, Belfast. **Hens.**—First, M. Stuart, Second, J. Montgomery. Highly Commended, R. Aruckle.

POWTERS (White Cocks).—Painting and First, G. J. Maclean, Edinburgh; Second, M. Sanderson, Edinburgh. Highly Commended, J. Wallace, Glasgow; J. Luis, Edinburgh; J. Ruthven, Glasgow. Commended, G. Ure, Dundee. **Hens.**—First and Second, M. Sanderson. Very Highly Commended, J. Montgomery. Highly Commended, J. Wallace, Glasgow; G. Ure, Dundee.

POWTERS (Blue Cocks).—First and Second Sp., J. H. Frame, Carlisle. Second, G. Ure, Dundee. Highly Commended, J. Wallace; G. Ure; J. Ruthven, Glasgow; D. Stewart, Perth. **Hens.**—First, W. Lightbody, Glasgow. Second, J. Ruthven. Very Highly Commended, W. Lightbody. Highly Commended, M. Stuart, Glasgow; J. Ruthven; M. Sanderson, Edinburgh.

POWTERS (Red Cocks).—First, J. Wallace, Glasgow. Second, J. Montgomery, Belfast. Highly Commended, M. Stuart, Glasgow; J. Luis, Edinburgh. **Hens.**—First and Second, G. Ure, Dundee.

POWTERS (Yellow Cocks).—First, G. Ure, Dundee. Second, J. Montgomery, Belfast. Highly Commended, H. Brown, Sheffield. **Hens.**—First, G. Ure. Second, M. Stuart, Glasgow. Highly Commended, J. Wallace. Commended, J. Butler, Glasgow; J. Wallace.

POWTERS (Cocks, Any other colour).—First, J. Luis, Edinburgh. Second, J. Wallace, Glasgow. Highly Commended, M. Stuart, Glasgow; W. Geddes, Glasgow; J. Paul, Glasgow; J. Wallace. Commended, J. Muir, Glasgow. **Hens.**—First, W. Lightbody, Glasgow. Second, J. Muir. Highly Commended, W. Geddes.

CARRIERS (Any colour).—Prize, F. Else, London. Very Highly Commended, R. Fulton, London. Highly Commended, J. Muir, Glasgow.

CARRIERS (Black Cocks).—First and Second, T. Colley, Sheffield. Highly

Commended, J. Wallace, Glasgow. **Hens.**—First, W. B. Van Haansbergen, Newcastle. Second, R. Fulton, London. Highly Commended, T. Colley. **CARRIERS (Dun Cocks).**—First, C. J. Samuels, Manchester. Second, T. Colley, Sheffield. Highly Commended, T. Colley; H. Yardley, Birmingham.

Hens.—First and Special, T. Colley. Second, J. Muir, Glasgow. Highly Commended, F. Else, London; T. Colley. Commended, R. Fulton, London. **SHORT-FACED TUMBLERS (Almonds).**—First and Special, M. Stuart, Glasgow. Second, R. Fulton, London. Highly Commended, J. Wallace, Glasgow; G. Ure, Dundee.

SHORT-FACED TUMBLERS (Mottles, Any colour).—First, G. Ure, Dundee (Black Mottles). Second, F. Else, London.

SHORT-FACED TUMBLERS (Any other colour or marking).—First, J. Wallace, Glasgow (Kites). Second, M. Stuart, Glasgow (Kites).

BREBS.—Medal, J. H. Frame, Carlisle.

BARS.—First, J. H. Frame, Carlisle. Second, W. B. Van Haansbergen, Newcastle. Highly Commended, H. Yardley, Birmingham.

FANTAILS.—First and Medal, F. Else, London. Second, G. Ure, Dundee. Highly Commended, F. Key, Beverley; W. B. Van Haansbergen.

JACOBINS.—First, R. Pickering, Carlisle. Second, W. Nelson, Johnstone. Highly Commended, F. Else, London.

TRUMPETERS.—W. Powell, Belfast. Second, W. B. Van Haansbergen. Highly Commended, J. H. Frame, Carlisle.

TURBITS.—First and Medal, J. R. Rennards, Helensburgh. Second, H. Yardley, Birmingham.

OWLS.—First, R. Pickering, Carlisle. Second, F. Else, London.

NUNS.—First, F. Key, Beverley. Second, H. Yardley, Birmingham. Highly Commended, T. Short, Glasgow.

MAGPIES.—First, J. Sharp, Johnstone. Second, T. Short, Glasgow. Highly Commended, F. Else, London.

COMMON TUMBLERS.—First, J. Sephton, Prescot. Second, J. Sharp, Johnstone (Blue Beards). Highly Commended, T. Short, Glasgow (Black Bald Pates); J. R. Rennards, Helensburgh.

OTHER BREEDS.—First, J. Sharp (Blue Brunswick). Second, A. Heath, Caine (Isabels). Third, C. J. Samuels, Manchester.

CANARIES.

EXTRA PRIZE (A Silver-plated Teapot for best Pair of Canaries).—Teapot, D. Duncan, Carron.

SCOTCH FANCY (Yellow Cocks).—First and Medal, G. Ayton, Glasgow. Second, A. Wilson, Wishaw. Third, T. Buchanan, Glasgow. Fourth, S. Brown, Glasgow. **Hens.**—First and Fourth, T. Buchanan. Second, J. Mair. Third, A. Wilson.

SCOTCH FANCY (Buff Cocks).—First, J. Smith, Dundee. Second, G. Ayton, Glasgow. Third, R. S. Wylie, Paisley. Fourth, M. W. Ruthven, Glasgow. **Hens.**—First and Medal, D. Duncan, Carron. Second, A. Kelly, Paisley. Third, J. Templeman, Glasgow. Fourth, M. Bell.

BELGIAN FANCY (Yellow Cocks).—First and Second, T. Buchanan. Third, J. Watt, Leith. Fourth, R. Forsyth, Edinburgh. **Hens.**—First and Sp., J. Watt. Second, S. Crawshaw, Lochee. Third, R. Forsyth. Fourth, J. J. Garden, Aberdeen.

BELGIAN FANCY (Buff Cocks).—First and Fourth, J. Watt, Leith. Second, W. Jamieson, Glasgow. Third, S. Crawshaw, Lochee. **Hens.**—First and Second, J. Watt. Third, W. Pitcaithly, Dunfermline. Fourth, R. Forsyth, Edinburgh.

PIEBALDS, SCOTCH FANCY (Yellow Cocks).—First and Sp., A. Wilson, Wishaw. Second, S. Brown, Glasgow. Third, H. Fisher, Glasgow. Fourth, C. M'Williams, Glasgow. **Hens.**—First, J. Crawford, Beith. Second and Third, H. Newall, Glasgow. Fourth, C. M'Williams.

PIEBALDS, SCOTCH FANCY (Buff Cocks).—First and Third, H. Newall. Second, H. Fisher, Glasgow. Fourth, N. M'Lean, Glasgow. **Hens.**—First, T. Christie, Glasgow. Second, D. Duncan, Carron. Third, H. Newall. Fourth, D. Stewart, Perth.

GOLDFINCH MULES (Yellow Cocks).—First, G. J. Barnesby, Derby. Second and Third, W. Kirk, Dunfermline. Fourth, T. Dougall, Carlisle.

GOLDFINCH MULES (Buff Cocks).—First, G. J. Barnesby. Second and Fourth, W. Kirk, Dunfermline. Third, T. Buchanan, Glasgow.

JUDGES.—**Pigeons:** Mr. T. J. Charlton, Bradford, and Mr. J. Miller, Glasgow; Umpire, Mr. A. Cowan, Ayr. **Canaries:** Mr. R. Crawford, Kilbirnie; Mr. W. Ferguson, Beith; Mr. G. Masterton, Glasgow; and Mr. N. M'Lean, Glasgow.

KENT AND MAIDSTONE POULTRY SHOW.

The show of cattle, sheep, pigs, poultry, wool, and roots, took place in the College Yard, Maidstone, on Tuesday, the 13th inst.

Spanish headed the list. There were four entries. The first prize was taken by a very fair pen; the next two pens were mongrels, and the fourth contained three small pullets. Of Dorkings there were three entries of old birds, most of which had sore hind claws; and ten entries of young birds, among which were some good birds. There were also two pens of Dorkings in the "Any other class," making in all fifteen pens of Dorking fowls. Game came next. There were seven pens of old birds, and six of chickens, all of which were Reds, and I noticed the winning birds were marked on the legs both with white and yellow tape, which is generally considered as a good reason for disqualifying them. Hampburghs were divided into Golden and Silver, and had one entry in each class; the pen of Golden, consisting of a Black-breasted Spangled cock, and two badly marked Golden-pencilled hens, while the Silvers were represented by a tolerable pen of Spangled birds. Bantams had two classes, old and young; two prizes in each class, and two entries in

one class, and three in the others. Four pens were Game Bantams, and one Black. The class for other breeds had five entries, three of Brahmans, one of Shanghaes, being a white cockerel and dark pullets, and a pen of coloured Dorkings.

Extra stock comprised a fine pen of single-combed White Dorkings, and three pens of Pigeons, a nice pair of small blue Owls, and two pairs of Fantails, one white, the other black.

Of Turkeys there were two entries, both by the same exhibitor. Of Aylesbury Ducks there were five entries, but some of the larger birds had stained bills. Ducks of other breeds mustered seven entries. A very pretty pen of Wild Ducks took first prize, a large pen of Greys with white flights was second, and a pen of Rouens commended. The remainder were imperfect Rouens.

It will at once be seen that Dorkings are the principal fowls shown, and the Committee should put them first, and give them most classes and prizes. Classes for White, Grey, and other coloured Dorkings would be better filled than those for Hamburgs. Game came second, and then Bantams.

Poultry was also exhibited the same day at Rye Cattle Show. I am very glad to hear of such exhibitions of poultry, but am quite sure we in the south require every such local show to improve our local fowls, to wit, Dorkings, whether White, Grey, Cuckoo, Speckled, or any other colour.—B. P. BRENT.

FOWLS FOR COLD WET DISTRICT.

ONE of your correspondents, a few weeks since, was inquiring for the most profitable sort of fowls. I suppose a good deal depends on climate and locality; but here, in our wet Lancashire, nothing succeeds so well as the cross-bred fowl, between the Spanish cock and the Golden Hamburg hen. The chickens are healthy, and easily reared; the pullets lay eggs equal in size and quality to the Spanish; they rarely want to sit; they are generally black, a good size, and handsome; and the cockerels are good for the table. In all respects I think them much better than the Pencilled or Spangled Hamburgs, which are not so hardy, lay smaller eggs, and not so many of them as the cross-breds.—T. G.

BIRMINGHAM POULTRY SHOW.

ALTHOUGH the sales of poultry, in the office set apart for the purpose, were not quite so numerous as last year, they realised rather more money.

Among the pens disposed of were Mr. Yardley's (Market Hall, Birmingham), first prize Buff Cochin pullets, for £20; Mr. Lawrence's second prize Yellow Jacobin Pigeons, for £20; Mr. James Wood's first prize Black-breasted Red Game, for £12 12s.; Mr. Elijah Smith's first prize Buff Cochin hens, for £12 12s.; Mr. James Wood's first prize Brown-breasted Red Game, for £12 12s.; Mrs. Seaman's first prize Aylesbury Ducks, for £12 12s.; Mr. Shorthose's first-prize pen of Partridge-feathered Cochins, for £10 10s.; Miss Beldon's first prize Silver Polish chickens, for £10 10s.; Mr. Jas. Fielding's first prize Spangled Hamburg chickens, for £10 10s.; Mrs. Hurt's second prize Silver-spangled Hamburg chickens, for £10 10s.; Mr. Aykroyd's first prize Duckwing Game, for £10 10s.; Mr. Cock's Black-breasted Red Game (single cocks), for £10 10s.; Mr. Swift's Game Bantams, for £10 10s.; Mr. Hulbert's Rouen Ducks, for £10 10s.; Miss Biggar's first prize Spanish pullets, for £10; Mr. Bates's commended Buff Cochin hen, for £10; Mr. Bishop's commended Buff Cochin cock, for £10; Mr. Poole's first prize Partridge-feathered Cochin cock for £10; Mr. Kelleway's first prize Game Bantam cock, for £10; and Mr. Postan's highly com-

mended Game Bantams, for £9 9s. Fifty other pens sold for sums varying from £8 10s. to £5.

We append a statement of the aggregate of the sales during the last twelve years:—

1853	204 pens	£1,755 4 6
1854		1,219 18 10
1855		1,145 8 6
1856		999 0 6
1857		804 17 0
1858		946 12 6
1859	192	856 1 0
1860	203	831 0 0

1863	280	1,054 15 6
1864	273	1,066 8 6

The Stewards for this department were G. C. Adkins, Esq., Messrs. F. Sabin, W. Lort, jun., and Mr. W. B. Mapplebeck, and their duties were discharged in a very efficient manner. The latter gentleman also undertook, and zealously performed, the very arduous task of superintending the reception of the birds and the dispersion of them to their several destinations. No sooner were the doors of the Hall closed on Thursday evening that this work commenced, and was continued, with scarcely any intermission, through the night, so that by ten o'clock on Friday morning the entire 1,677 pens of poultry, and the 290 pens of Pigeons, had either been despatched to the several railway stations, or were ready for delivery to such local exhibitors as had arranged to call for them. The promptitude and ability with which the complicated regulations for the accomplishment of this removal were carried out, entitle Mr. Mapplebeck to the warm thanks of the exhibitors.—(*Midland Counties Herald*.)

SATINETTE PIGEONS.

I AM much obliged by Mr. H. Noye's explanation respecting the pretty Satinettes, but he seems to disregard the distinction between a variety and a breed. The difference may be a trifle, yet it makes all the difference between us. I am quite willing to admit them as a distinct variety, but of the same breed as Turbits—in fact, a distinct variety of the Turbit-breed or kind. How far they may be superior to the other varieties of Turbits must remain a mere matter of private fancy.

A correspondent who has bred them informs me he paired a Satinette with a Turbit, and the produce were to all intents Turbits. Change of colour, the addition of a turned crown, or a few feathers on the feet is not enough to constitute a distinct breed or sort.—B. P. BRENT.

REGICIDE AMONG BEES.

I AM very glad that "A LANARKSHIRE BEE-KEEPER" has again directed attention to this interesting subject. It is all very well for such *ad captandum* writers as Dr. Cumming to exclaim "that bees are regicides" is not true. They never kill their queen; they love and are loyal to her, and obey her commands," and so on through a mortal *Times* column, of what one of his reviewers happily styles "a mellifluous compound of nonsense and error;" but the fact unfortunately remains that bees are sometimes provokingly apt to slaughter their queens, and it is only by directing the attention of apiarists generally to the subject, and by carefully collecting and comparing facts and observations bearing upon it, that we can hope fully to investigate, and perchance, even to explain what now appears a most inexplicable and unsatisfactory chapter in the natural history of the honey bee.

Taking Huber for my guide, whenever I discovered a queen imprisoned in a knot of workers I used to fancy that she must either be a stranger, or at least a supernumerary queen produced in the same hive; and I well remember, on first finding a young imprisoned queen in a small queen-rearing box or nucleus, the long and unavailing search I at once made in the hope of discovering a second princess. On another occasion of the same kind I fancied the juvenile queen must have mistaken her hive in returning from a nuptial trip, and, therefore, having released her from her sisters' pitiless embrace, I thought I could promptly and safely resolve my doubts by introducing her to a single worker from the neighbouring colony, to which I fancied

she belonged. The solution was certainly prompt, but could scarcely be deemed satisfactory, since in little more than a second the unfortunate queen lay in the agonies of death, having been instantly stung by the strange worker to which she had been so inconsiderately introduced. Here, then, was another blow to my faith in the infallibility of Huber, who declares that "the workers at no time will attempt to employ their stings against a stranger queen."

In process of time I became aware that queen bees were really liable to hostile attacks by their own workers, such attacks assuming the form of rigorous imprisonment in a dense cluster of their rebellious children; and at length I witnessed several instances which I have already related, and in which these incarcerations terminated fatally in the case of young and perfectly fertile queens.

Although I had ascertained that princesses were very liable to these attacks on their return from their wedding flights, I was long under the impression that in their case a fatal termination was not to be dreaded, and even went the length of imagining that a brief period of imprisonment might possibly be beneficial.

Revenons à nos moutons. Where was I when I digressed? O, saying that I had fancied that a fatal termination of a regicidal attack on a princess was not to be dreaded. But before relating the facts which have this season awakened me from my dream of security, permit me a few words in reference to the hypothesis submitted by your esteemed Lanarkshire correspondent, and which hypothesis these facts will, I fancy, go far to disprove. It may be remembered that the idea that regicidal attacks might be initiated by stranger bees has been already promulgated in these pages by that careful and accurate observer "R. S.,"* and as coming from such a quarter it is undoubtedly well worthy attention. Still, I am bound to say that, so far as my observation extends, I have never met with an instance in which I could trace a regicidal attack to the presence of stranger bees. When these are introduced in large numbers, as in uniting stocks in autumn, the risk is undoubtedly great, and the queen not unfrequently falls a victim to the involuntary invasion; but so far as my experience extends, mere robber bees neither molest nor pay the slightest attention to the native queen. In those instances which I have witnessed she has passed totally unregarded, the marauders appearing too intent on plunder to take the least notice of her. In some cases it may, of course, be different: I can only speak of what I have myself seen.

But to return to the experience which completely upset all my preconceived notions with regard to what I had supposed to be the innocuous if not actually beneficial imprisonment of youthful queens. On the 20th of last June, when honey was so plentiful that no bee would dream of pilfering from others what she could so readily collect for herself, I opened a small nucleus-box, and found the young queen absent. During my examination she returned with evident signs of impregnation, and was instantly seized and imprisoned in a dense knot of workers. Having released her from her persecutors, I closed the box and let her fly. She returned to the hive's mouth, where she was instantly seized by one of the sentinels, but broke away from it and flew off again. The same thing was repeated once or twice, but ultimately she eluded the guard and slipped into the hive. As the day advanced I inferred from the restless demeanour of the workers that she was again in durane; and as on examining the hive in the evening this proved to be the case, I thought I would err on the side of caution by ensconcing her in a queen-cage within the hive itself until the next day, when on her release she was well received, and remained without further molestation. Subsequent events make it probable that she owed her life to my precaution.

Later in the summer I missed a young queen, and ultimately discovered her lifeless on the ground immediately in front of her hive, and in that shrunken and distorted condition which marks the hapless victim of a regicidal attack. I could not by the closest examination discover any sign of impregnation; but I had little doubt of her having been destroyed on her return from an excursion, whilst her demise was at any rate a fatal blow to my pretty theory of beneficial imprisonment. I had not long to wait for something even more conclusive.

At this time I possessed a young Italian princess, with which I was absolutely in love. She was not remarkably large, but in colour, grace, and symmetry I have rarely beheld her equal. Whether within the hive or on the wing she was equally lithe and agile, and she was accordingly watched with an admiring interest accorded to but few of the inhabitants of my apiary. One day I was somewhat startled at finding in her hive that horrible little knot of workers, with whose appearance I am unfortunately but too familiar. Warned by the misfortune which I have just related, I determined to leave nothing to chance, and having thus caught them *in flagrante delicto*, I congratulated myself on being, as I supposed, in time to save my especial little pet from the fate which had only a few days before overtaken her unfortunate sister. Judge, then, of my mortification on gently dispersing the cluster at finding its nucleus to consist only of the poor shrivelled and distorted carcase of my so recently beautiful queen! On examination I had the additional mortification of finding conclusive evidence of a successful wedding trip, so that it became apparent that my hopes had indeed been blasted in the very moment of their fruition.

In neither of the instances above related can I discern anything to countenance the hypothesis, that regicidal attacks are initiated by robbers. It is true, that in the first case the hive was open at the commencement, but not only was no plundering perceptible, but, as stated before, I do not believe there was such a thing as a robber bee at that season of plenty; and even setting this aside it will scarcely be maintained that the sentinels at the entrance by whom the queen was afterwards repeatedly assaulted belonged to the marauding fraternity. In the other case I can only say, that I could discover no appearance of an attack by robber bees, and that I am satisfied that none had taken place.—A DEVONSHIRE BEE-KEEPER.

SWARMING VERSUS DEPRIVING.

My experience does not all coincide with that of your correspondent "J. E. B." who at page 444 seems to imply that allowing stock-hives to swarm increases their honey store; the inverse of this rule holds good with us. Surely the queens of the storified hives must have been worn out by age, or there was something radically wrong with the management of these hives, when such an invidious comparison could be drawn.

Acting on the principle that union is strength, both of population and honey store, the escape of a swarm from a depriving-hive, despite the best efforts to avert it, is looked upon as a great misfortune by us northerners, and it is at once returned, should it stubbornly refuse to remain, even though royal cells be destroyed. The queen herself is often sacrificed, so as to keep up the population; but if the swarm is hived another prime one is as soon as possible procured and added to the emigrants, with the view of combining a sufficient force for the getting up or completing supers.

No better proof of the success of the "conservative principle" need be looked for than the interesting report of that thoroughly practical conservative bee-master Mr. S. Bevan Fox, "My Apiary in 1864," published in a recent Number.

I made an involuntary convert to the depriving system this year as follows:—A most enthusiastic bee-keeper in this quarter, of the old swarming school, who usually spares neither time, trouble, nor sugar, to have the honour of hiving the earliest swarm in the district, was left behind this season, and chancing to meet me was lamenting over his bad luck. He told me he had kept a swarm in one Stewarton octagon box purposely to have an unusually early swarm; the bees had been long "lying out," but somehow or other would not come off. He was not a little surprised on my telling him that his anxiety to effect his desire was in all probability the cause of its frustration. It was more than likely that the queen, in the small area of available comb in a single Stewarton had not room sufficient to unburden herself of her eggs, so as to fit her to be in a condition to fly off with the longed-for swarm. In addition, he was a considerable loser by allowing his bees to hang out idle during the then capital honey-gathering season. Beaten as he was, he thought he could not do better than

* Vide JOURNAL OF HORTICULTURE, Vol. VI., page 67.

follow my advice of giving a second breeding-box below at once, shortly thereafter a honey one, and further breeding-space gradually as the stock might require it. The result was his taking off a splendid super of clover honey, and a second beautiful one of the gleanings of the heather and on its return from the moors a very heavy stock. On showing me with pride the last of these trophies, he told me as long as he kept bees he would never allow a hive to swarm, to which resolution I made the addendum always providing he kept his queens young and vigorous, for which additional hint he expressed his further acknowledgements to—A RENFREWSHIRE BEE-KEEPER.

WILTSHIRE BACON VERSUS HERTFORDSHIRE BACON.

SOME weeks ago I read in your paper how to make bacon by a "WILTSHIRE RECTOR." Now, I know better; and what your Rector tells us to do about letting out the brine by a hole in the corner of the tray, taking out the bacon when cured, rubbing it with bran, and hanging it in the kitchen, you may just as well rub it with a brickbat and hang it in the sun. If you want good bacon, do as I do, place your side of a good-sized pig in your tray. If it weighs 50 lbs., take of common salt 2 lbs., bay salt 2 lbs., saltpetre 4 ozs., mix these salts well together and rub the mixture in thoroughly. This is the first day's work. The second day take 1½ lb. sugar and half a pint of vinegar, boil them together and pour on to your bacon, as is to be, hot, then rub the salts and the vinegar and sugar well in. Do this and turn the sides every day for a month, never let off the brine, then take them out and smoke them gently in wood smoke for three weeks. If my bacon does not beat the Wiltshire out and out, I am not—SALLY GRISKIN.

P.S.—Some people like their bacon hogs singed. My grandfather, a Berkshire man, would insist that no bacon was good unless the hogs were singed. He was a blue-eyed old Saxon, and like all of that race hard to move. I believe there is no occasion to singe bacon hogs. My neighbour, the doctor's wife, a Warwickshire lady, tells me they never use sugar in curing their bacon in the north, and never smoke it, drying it in the kitchen. Nasty stuff, I say.

CURING BACON.

ANOTHER inquiry concerning bacon! and from "Ballinasloe," in the land of Bacon! I shall henceforth attach a more literal meaning (not indeed forgetting the figurative), to the phrase, "Every man wants to save his bacon."

Matters relating to food must always be ranked among important matters. Thus an army kept on short rations for a week would be beaten by an inferior force of well-fed—say bacon-fed, to the last hour.

In replying to my Irish correspondent, I would say first, that much depends upon the pig. Not to take the extreme case, that without a pig there would, manifestly, be no bacon at all; but with an inferior pig, inferior in breed and feed, the bacon will be inferior too.

I would presume, then, that my inquirer has nothing to do with the Irish pig described in a book lying before me, in these not favourable words. "In Ireland the native pig is tall, long-legged, bony, heavy-eared, coarse-haired, and by no means possessing half so much the appearance of domestic swine as they do of the wild boar." I remember seeing large droves of such pigs five and twenty years ago, but I hope they are no more visible anywhere.

The best pig for a gentleman's pig—*i. e.*, where not wanted of a large size, is the Berkshire, very slightly crossed with the Chinese. I began with the rule of killing when the supposed weight was eight score pounds, but now that little mouths begin to be larger mouths, I kill at nine score.

As to the component parts of the pickle. We use a stone of salt for the whole pig of nine score including hams, faces, &c., and 1 lb. of saltpetre; nothing else whatever is used for the fitches.

A person accustomed to salting bacon soon sees, so my cook informs me, when the meat will take in no more salt. True Wiltshire people use no other ingredients even for the

hams, but usually they are cured more highly, *vide* any cookery book at hand, and choose the receipt most pleasing.—WILTSHIRE RECTOR.

LARGE IMPORTATION OF EGGS.—The enormous number of 291,597,240 eggs has been imported into this country in the first ten months of the present year!—not very far from a million a-day.

OUR LETTER BOX.

DARLINGTON POULTRY SHOW.—I have received a Game cock from the Darlington Show which does not belong to me. If the owner will write and describe the bird I shall be happy to send it to him.—HENRY HEATON, Lower Broughton, Manchester.

CHARACTERISTICS OF BLACK HAMBURGS (*Cornish Subscriber*).—The shape and comb should be the same as the other varieties of this breed. The deaf ear should be quite white, the face should not.

GAME COCKEREL CROWING (*J. F. S.*).—Although at the age of four months some cock chickens make a sort of noise that may by courtesy be called crowing, yet it is nothing extraordinary that a bird two months older should be silent. The Game are the likeliest to crow early, and the bird in question may have crowed many times without having been heard.

DISEASED FOWLS (*Lady Subscriber*).—We fear your fowls have the roup. If there are but few cases separate the sick from the healthy, and give Baily's pills. If all are affected, and you have too many to treat as invalids, give stimulants—strong beer is the best, and put camphor in all their water.

TAMING PARROQUETS (*Idem*).—We have the small Parroquets, if you mean the Undulatas, perfectly tame, and have never had any difficulty with them. We have constantly seen them at liberty flying about in rooms. A tuft of growing grass is a bribe they can never resist, and they will go anywhere for it.

DIARRHOEA IN COCHIN-CHINA FOWLS (*H. W.*).—You must continue the purging till the evacuations assume a natural and healthy state and colour. Feed on the most nourishing things, as oatmeal, but very little at a time. Discontinue the cabbage and Indian corn. We have little doubt she has picked up something that is injurious if not poisonous; but castor-oil will carry it off if ulcerated.

COCK'S LEG ULCERATED (*Lenton*).—We know no poultry doctors. If the bird keeps in good condition you will only have to wash the wound constantly, and keep it dressed with citron ointment as soon as the discharge diminishes. Generally speaking, these affections of the leg are the precursors of fatal maladies; but in these instances they are accompanied by shrivelling of the limb and wasting of the body. The absence of these symptoms in your case would seem to point to an accidental cause for the ailment.

TURBET PIGEON AFFECTED WITH COLD (*M. A.*).—To administer cod-liver oil to Pigeons, mix flour or meal with the oil to a stiffish paste, roll it into pellets, and give the bird one every twelve hours. The pellet will be more easily swallowed if a few drops of water are first put into the bird's mouth.—E. P. B.

SILVER-GREY RABBIT SKINS (*Coney*).—Refer to the London list of furriers, and write to some of them if you have a dozen or more skins.

CANARY (*W. B. A.*).—As the bird becomes dull and heavy, and his feathers ruffle only when hung from the curtain-pole near the window, it is very probable that the fumes of the gas collect there during this season, as the heated fumes rise to near the ceiling and rush to the coldest part of the room. Let the cage be suspended in a warmer part of the room, and lower from the ceiling.

CANARIES MOUFLING (*Canariensis*).—1st, Canaries occasionally lose their voice from cold. Benefit may be derived from dissolving Spanish liquorice in his drinking-water. 2nd, Maw seed—that is, poppy seed, is generally much relished by the birds, and I think it much more conducive to their health than hemp or rape seed. 3rd, Bread is not injurious, and you may let your bird eat as much as he likes. 4th, To cut the bird's claws, take him in your hand, and looking through the nails to see how far the quick extends, then cut off the remainder with a sharp pair of scissors.—B. P. B.

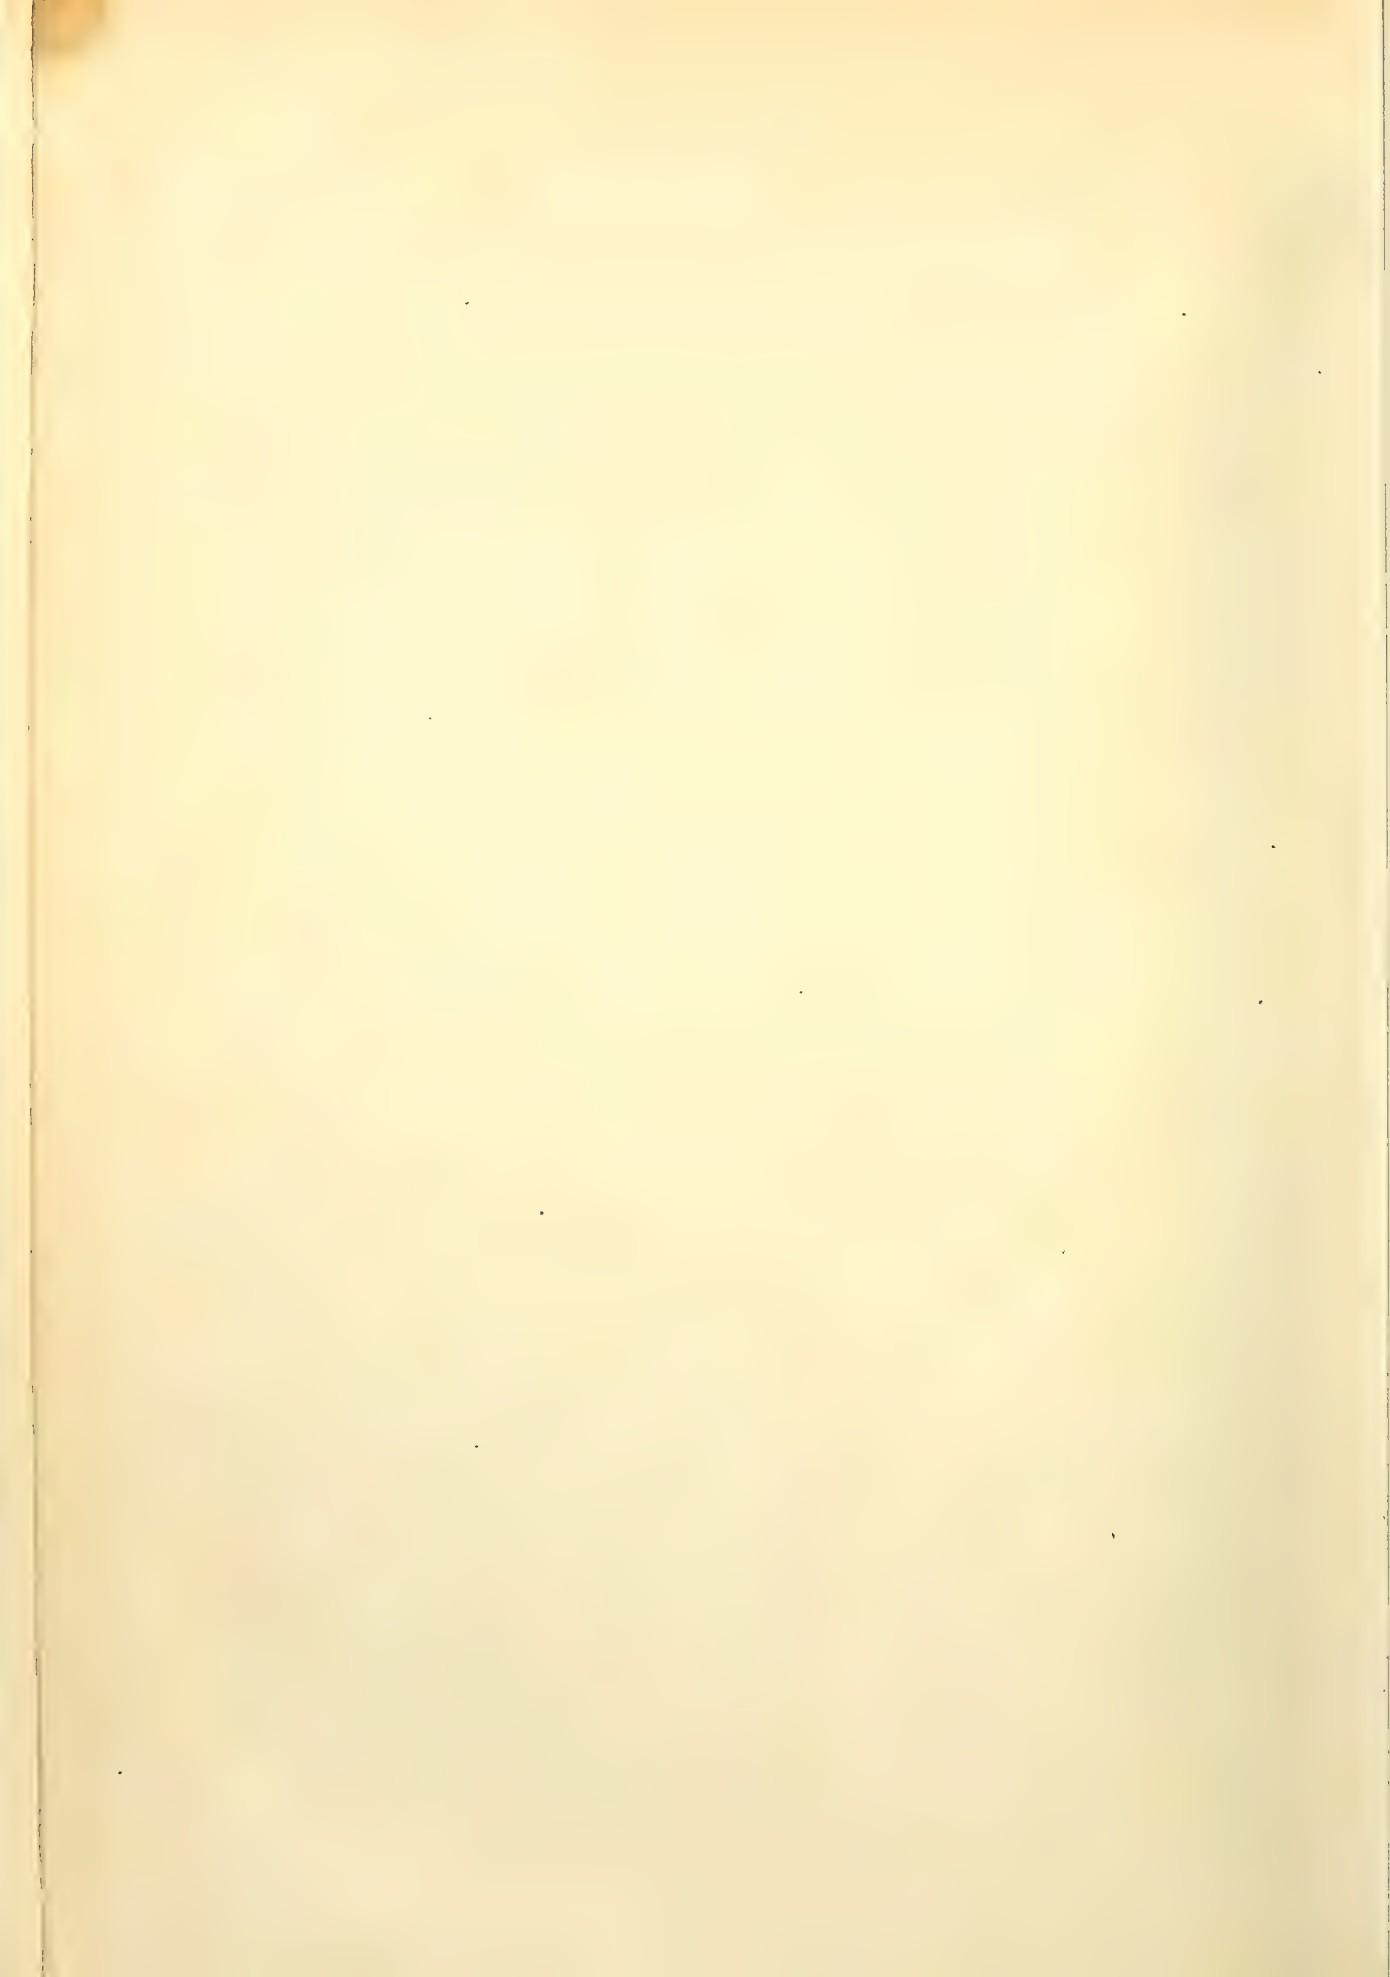

SUPERSTITIONS ABOUT BEES (*J. Jackson*).—Your letter is written in a good spirit, but is totally at variance with our own experience, and the experience of all apiarists. We are very glad that you derive assistance from our pages.

LONDON MARKETS.—NOVEMBER 21.

POULTRY.

The character of the Christmas market of late years has been almost monotonous—few first-class goods, they consequently make good prices; large quantities of inferior poultry, which finds a sale with difficulty, but is evidently remunerative from the fact it is persevered in. During the first few years of the Goose clubs the supply of these birds was inadequate, they therefore made very large prices. There are plenty of them now, but they sell well. One man sends up many thousands. Poultry is in the ascendant during this week in Sussex, Essex, Norfolk, Suffolk, Lincolnshire, and many parts of Ireland, Scotland, France, Holland, and Belgium. From the various points all come to Leadenhall as their common centre, and the market during this week is a perfectly unique sight. We do not quote Turkeys. If of good quality they are like meat, and valuable, according to weight, rising rapidly after the limit of eighteen pounds is passed.
